Dr. Murray's report seems to contain strong evidence of two definite and important facts: one, that of the mischievous effect of stimulants in the treatment of the disease already referred to; the other, that its characteristic symptom is paralysis of the sympathetic nervous system. With this knowledge to direct our experiments, we may surely hope to arrive at an intelligent mode of treatment.

Snake Poison.

The *Friend of India* says that Dr. Fayerer's prolonged and elaborate experiments on the influence of snake

poison have resulted in the conclusion that, if an animal, and probably a man, be fairly bitten by a fresh and vigorous cobra or daboia, it, or he, will inevitably succumb, unless some immediate and direct method of arresting the entry of the poison into the circulation be practised. Two surgeons, accustomed to such operations, speedily applied both ligatures and cauterization, but in vain in each case. The moment of time that intervenes between the injection of the snake poison by the powerful maxillary muscles through the tube-like fang, into the minute blood-vessels of the part, and the application of the ligature and actual cautery, is sufficient to allow of the entry of the poison into the circulation, and this reaching the nerve centres, even in a small quantity, may prove fatal. Both, however, should be had recourse to. Dr. Fayerer remarks that to conceive of an antidote, in the true sense of the term, to snake poison, one must imagine a substance so subtle as to follow, overtake, and neutralize the venom in the blood, or that shall have the power of counteracting and neutralizing the deadly influence it has exerted on the vital forces. Such a substance has still to be found, and present experience of the action of drugs does not lead to hopeful anticipation that we shall find it. But where the poisonous effects are produced in a minor degree, or when the secondary consequences are to be dealt with, much may be done to aid the natural forces in bringing about recovery.

Chloral.

Dr. O. LIEBRICH's recent paper at the Paris Academy of Sciences on the action of *Chloral* says it is a trichloride of aldehyde, and is soluble in water, and as in this solution it exercises no irritant effect, it is very suitable for absorption into the economy. It takes its place between ether and chloroform as an anæsthetic.

Experiments made on rabbits have given the most satisfactory results. Profound and calm sleep has been maintained for eight or ten hours, and Dr. Liebrich adds that the rabbits on awakening have manifested none of the usual results, and have proceeded to eat with avidity.

St. Bartholomew's Hospital.

THE lay Governors of this old charity have dismissed Dr. Mayo, an Oxford man, and Fellow of his College, from the office of House Physician. His crime is that he protested against the gigantic sham of prescribing for out-patients at the rate of forty seconds for each patient. To a mere complaint he received no answer. When he took further measures, he was referred to the contract he signed on taking office. When he took his stand on that contract, and refused to receive the orders of a paid official, he was dismissed.

This contempt of right demands the notice of the honorary staff. There are plenty of abuses yet subsisting, but we feel that the great leaders of the Profession who hold office at St. Bartholomew's, are bound to see that a junior but worthy member of the Profession shall not be insulted without the world knowing their disapproval.

When next the Prince of Wales goes round, and a lay Governor accompanies him, and glorifies all the arrangements, perhaps the surgeon or physician present will be good enough to explain that without gratuitous medical labour the work could not be carried on, but that those

who really cure the patients may be badgered by any Jack in office. The students, as well as the outside Profession, see the grievous wrong that is being done, and will take but little more provocation to drive all pupils to other schools.

No doubt overwork may be met with elsewhere, but at Bartholomew's it is at last unendurable, and yet no step is taken to remedy the evil. Prescribing for hundreds per hour is a solemn farce.

Women's Medical Mission.

WHATEVER may be the aptitude or inaptitude of the female mind for the practice of medicine it is obvious that female medicine has established a certain position, and is gradually pushing its way into public recognition and toleration; and it is not, we consider, a subject for regret that it should do so, for in no other way can the capability of women to endure the hardest trials of nerve or to perform the sternest duties of man be determined. Woman's mission in this direction has, in truth, had little to contend with in the way of man's opposition. The Profession has wisely abstained from adopting an antagonism which might have been attributed to self-interest, and the public is just now in the innovating temper which tolerates such pretensions all the more easily because they have the smack of revolution about them.

We have never opposed Female Doctoring on any plea of the incapacity of women to learn certain branches of medicine or to practise them, on occasion. If women's mind-strength were equal to the masculine standard, or if her expectations, aspirations, and desires extended no further than the successful practice of a Profession, we see no mental inferiority which need disqualify women from medical science. But, after all, hardness and unfeminine self-confidence are *not* strength of nerve, nor can any woman unfrock herself, however hard she may try, of softer domestic and maternal instincts and hopes; and this mental constitution must, we believe, for ever disqualify the great majority of women, if not from medical practice, at least from anything like professional success.

Charing-Cross Hospital.

THERE is a vacancy at this hospital which does not seem easy to fill, and we therefore bring it thus prominently forward. The following advertisement has lately appeared a great many times in a daily paper:—

CHARING-CROSS HOSPITAL, WEST STRAND,
W.C.—The Office of Physician for the Treatment of Diseases of the Skin at this Hospital being Vacant, gentlemen who may be desirous of becoming candidates for the same are requested to send their testimonials, diplomas, &c., to me not later than Tuesday, the 29th instant, at two o'clock.

The Physician for the Treatment of Diseases of the Skin is required to have a degree from one of the Universities recognized by the General Medical Council, and to be a Fellow or Member of the Royal College of Physicians of London.

HENRY WOOLCOTT, Secretary.

We must add that this vacancy was advertised several months ago, and we are informed that on that occasion a well-known physician was actually elected to the post, but that the Governors were induced to make this election conditional on his vacating all other appointments "*within a month.*" This condition was not complied with, and we are certainly glad to find some one in the Profession ready to resist the demands made by Governors on the gratuitous labour of medical men, when they are

accompanied by such scant courtesy. For a small hospital like Charing-Cross to exhibit such ridiculous jealousy as to refuse to allow a physician to one of its scarcely formed departments to employ his talents elsewhere is simply suicidal. What may be the consequence to the School of this act of selfishness we have no wish to inquire. We can only say that, after the last pretended election being rendered void by straining a rule almost to the breaking point, the hospital does not deserve to obtain a physician of the standing it might otherwise have secured.

If, for the honour of serving in gratuitous offices, medical men are to be treated with less consideration than many *gentlemen* bestow on their footmen, and no one ventures to decline the honour, physicians and surgeons may some day be expected to black the boots of the lay Governors when they enter the hospital.

The Medical Officer of the Privy Council.

IN the new Blue Book of the Medical Officer of the Privy Council we are glad to observe that Mr. Simon is not ready to extend the Contagious Diseases Act to the civil population. As we have often had occasion to differ from Mr. Simon, and to criticise in him an apparent tendency to be led away by others, in spite of his own independent order of mind, we have the greater pleasure in observing that he makes a stand here. We trust that he will not be content with expressing an opinion once. We remember the sensation he made when he went to the Medical Teachers' Association and delivered the most liberal address that had been heard for years; but what has come of it? The matter has been suffered to drop. Here, again, is an exceedingly liberal utterance about the effervescence that has appeared concerning contagious diseases. Is it a single utterance, or will it be acted upon?

We are thus concerned to fathom Mr. Simon's opinions, as it is rumoured that his views on the Medical Council are totally at variance with the Profession at large. It is but a rumour, but a very prevalent one, that Mr. Simon favours the notion of a small Government-appointed Council, and a centralization, which would sweep from the Profession every chance of self-government, and reduce it to dependence on a Ministerial *bureau*. Such a scheme would rouse the anger of the most apathetic of professions. Its supporters would be denounced as traitors to their brethren. The perpetrators of such an outrage would be execrated by the army of medical practitioners who demand a voice in the existing Council, and have faith enough in their power of self-government to resist being handed over to the tender mercies of a subservient *bureau*. Mr. Simon should be aware that the incredible rumour as to his views is so general that the Profession would gladly hear it contradicted on his own authority.

The Newport Poisoning Case.

THE adjourned inquest on this strange case, where a boy charged himself with poisoning a child, the daughter of his employer, was held on Thursday. Dr. Taylor had made an analysis, but, failing to find anything, the jury requested that the case be referred to Dr. C. Meymott Tidy, of the London Hospital, for examination and analysis. On Thursday, Mr. Brewer was examined and

stated that the symptoms were not those of poisoning, the boy himself asserting that what he had previously said was false. The Coroner then read the following letter from Dr. Tidy :—

“The Laboratory, London Hospital, Medical College,
Sept. 13, 1869.

“Re Emily Amelia Collier, deceased.

“SIR,—I received, Sept. 4, at the laboratory, through Mr. J. G. Huxtable, Chief Superintendent of Police—

“1. A small wooden barrel containing part of a fowl.

“2. An earthenware jar, corked, tied over with red tape, sealed with red wax, seal being unbroken, and marked with the letter T.

“It was labelled,—

“‘Case of E. A. Collier, Newport.’

“Delivered to Superintendent Huxtable—Part of liver, part of heart, part of the lungs, the kidney, portion of intestines.

“1. The chicken was entirely dried up, and the greater part of it had been removed. I submitted portion to a complete analysis, but found no traces of any poison whatever.

“2. I cut open that portion of the intestines that were in the jar, but found nothing whatever unnatural; nor, so far as their state of preservation would admit of examination, did I find any peculiar after-death appearances in those portions of the viscera submitted to me requiring notice, each and all of which I examined.

“I then submitted (1) the intestines, (2) the liver, (3) the lungs and kidney, separately, to a most careful and systematic analysis, for both mineral and vegetable poisons, but with entirely negative results.

“My analysis therefore fails to prove that the deceased, Emily Amelia Collier, died from the effects of poison.

“C. MEYMOTT TIDY, M.B., F.C.S.,
Lecturer on Chemistry at the London
Hospital, Master in Surgery, &c.”

The inquest was again adjourned.

Lunacy in France.

WE have often spoken of the apparent increase of lunacy as distinguished from the actual. It appears that the same condition of things prevails in France; for while the Census of 1851 gave a total of 4,625 lunatics, the number in 1855 was 60,290, and in 1861 the numbers had reached 84,214. In 1867 they were 90,739. It appears, therefore, that in 1861 there were 124 cases of lunacy to every 100,000 inhabitants of France, and that in 1867 there were 133 cases. According to the last annual report, the number of lunatics in England was 53,177, and this was an increase of more than 2,000 on the previous year. The explanations we have so often offered as to our own lunatics are, we do not doubt, equally applicable to those of France.

Outdoor Relief.

MEDICAL societies have often had their say on this subject. It is but fair, therefore, to record the opinion of the relieving officers, who see so much of the working of our laws.

The Metropolitan Relieving Officers' Association, in view of changes that are being made among the unions and parishes of London, have adopted the following recommendations, and forwarded them to the Poor-law Board :—

“1. That, in the opinion of this association, the relief districts of the metropolis should, as opportunities occur, be re-arranged; that no relieving officer should be required to administer relief to a district of which the average number of recipients during the preceding five years has exceeded 1,000 persons weekly; and that every relieving officer should have at his entire command the services of an assistant, who should be a young man of good character and education, with a progressive salary. Thus, a staff of officers would be efficiently

trained to a service requiring as much wisdom, patience, and discrimination as any other necessary for the government, protection, and education of the people. 2. That the relieving officer should pay and administer the relief of all paupers in his district, as the appointment of other officers for this purpose destroys the proper weekly supervision necessary to keep up his knowledge of the circumstances and condition of the recipients. 3. That in the opinion of this association it is desirable, as opportunities occur, relief stations should be established in central positions in each district, and that persons in receipt of out-door relief should not be required to attend workhouses for that purpose.”

The association believes that if these suggestions were carried out it would conduce to the benefit of the poor, the comfort and efficiency of officers, and ultimately to a diminution of the rates.

The Vaccination Question.

THE case of the little girl which excited so much sympathy at the police-court has been officially inquired into by order of the Privy Council. Dr. Seaton, after investigation, addressed the following letter to the magistrate before whom the case had come :—

“8, Richmond-terrace, Whitehall, Sept. 14.

“SIR,—The allegation of injury to a child's health from the use of improper lymph in the performance of vaccination, which was under your notice on Friday last, involves considerations of so much consequence that I offer no apology for writing to you to inform you—first, that whenever such allegations are made as affecting public vaccinators, or whenever intimation or suspicion of either malpractice or mishap in the conduct of public vaccination comes in any way to the notice of the Privy Council, official inquiry is always made; and, secondly, that inquiry has therefore been made into the particular case to which your attention was called. Acting on the general instructions I have in regard to all such cases, I, on reading what had taken place at Bow-street, went at once to Mr. Bennett's vaccination station, examined his books, and found entry of the vaccination of the child (Alice Hudson) said to have been contaminated, with due record also of the source from which the lymph employed had been obtained. The lymph source was a child between three and four months old, named Pratt, residing in Great Wild-street. I went to see this child, and found it as plump and healthy a child as could well be. It was entirely free from any cutaneous eruption or trace of any ailment whatever; and I was assured by its mother and by others that it enjoyed perfect health from its birth. It had on its arms the cicatrices left by normal vaccination. I then went to see the child Hudson—a very flabby and delicate child, who had been vaccinated along with another child at Mr. Bennett's station on the 19th August (not one of the regular vaccination days), by Mr. Bennett's assistant. It appeared from the mother's statement that Mr. Bennett himself saw both cases a week afterwards; that they were doing well, and had no eruption; that from one of the children (not Hudson) Mr. Bennett, took some lymph, but that from the other he declined to take any on account of the child's delicacy. It was not till ten days after this, and consequently not for a full week after the active phenomenon of vaccination had subsided, that (on September 4)—after a day or two of previous indisposition—an eruption came out on the child Alice Hudson. The eruption is apparently eczema, aggravated by the child's ill-nourished and chetic condition. These facts are, I think, sufficient to set at rest the notion of there having been any transmission of disease from one child to the other. Whether the vaccination may have had any part in evolving in the child Hudson an affection extant in its own system is another, and may be quite an open question. The events were in too close proximity not to raise the suspicion of it. On the other hand, these eruptions are constantly being met with in children who have not been vaccinated, and their most common cause—unsuitable diet—was not wanting in this case. But independent of this question, I must not withhold the expression of the opinion I formed that the child's state of health, when presented for vaccination, rendered it desirable that the vaccination should be postponed, and it is greatly to be regretted that the proper course of referring the parents to Mr Bennett himself, at the appointed time, was not adhered to,

and that the assistant should, without authority, and contrary to regulations, but doubtless with a kind desire to save trouble to the parents, have proceeded to vaccinate the child himself. Four children besides Hudson were vaccinated with lymph taken from the child Pratt. Two of these have gone away and cannot be traced; the other two I have seen, and both went through the vaccination regularly. It has been said that the child living in the same house as Hudson had had, in a less degree, the same eruption; but this is a mistake—the fact being that this child, at the time the vaccination was at its height, had a sprinkling of what is termed 'vaccine-lichen'—an eruption of short duration, familiar to vaccinators, and referred to in the official instructions as not unfrequently occurring at that stage, especially when the weather is hot.—I have the honour to be, your obedient servant,

"EDWARD SEATON, M.D.,

"Senior Medical Inspector of Her Majesty's Privy Council.

"To James Vaughan, Esq., police magistrate,
Bow-street."

Dr. Pettenkofer's Cholera Theory.

THE local Indian Governments and administrations have been instructed to institute experiments for testing, in some well-selected civil stations, Dr. Pettenkofer's theory regarding the origin and propagation of cholera. This theory is that the infecting matter of cholera is developed from a germ, which, as long as it remains a germ, is powerless to produce disease, but which is developed into infecting matter in the sub-soil, if this affords a suitable nidus. After development (if the superincumbent layers are permeable) the infecting matter ascends and the disease is evolved. The infecting matter may enter water and poison it, but the *germ* cannot be developed in water. The conditions in the subsoil which produce the infecting matter are a certain degree of moisture (a soil may be either too dry or too wet to favour the development of the germ, and thus increase or decrease of moisture, as the case may be, will produce the same result), and the presence of organic matter, which washes down through any permeable soil and accumulates in the sub-soil water. The chief point to be observed in testing this theory is the association of the occurrence of cholera in any locality with a change in the amount of sub-soil moisture. The mode of testing the increase or decrease of this is by ascertaining the variations of the water-level in wells reserved exclusively *ad hoc*, and this is easily done by means of a simple apparatus.

Cholera in India.

BY the last India and China mails just arrived, it appears there is much sickness at Shanghai. There is also a painful report as to the health of troops at Lucknow. The 41st and 102nd Regiments suffer most. At Umritsur there were from seventy to ninety deaths from cholera daily. In the fortress at Gwalior cholera had also broken out, and by latest telegram it seemed that Dr. Hales, who had been unremitting in his attentions, was lying in a most dangerous state. It is stated that in some cases Dr. Young's proposal to inject ammonia subcutaneously had been tried, but no successful case is mentioned. Some who had rallied afterwards died from fever, said to be set up by the remedy.

SUMMONSES have been issued against the Directors of the Albert on a charge of conspiracy. They are to be heard next Saturday.

A MAN has been fined £20 for employing meat unfit for human food in the manufacture of sausages.

THE death is announced of Dr. W. J. Bradford, T.C.D. He lately had charge of the North London Post Office District.

THE *Atrato* was placed in quarantine at the Mother-bank last week, on account of yellow fever having occurred on board. She was released on Sunday.

THE death of Professor Graham, F.R.S., is announced, in the sixty-fourth year of his age. The learned gentleman was Master of the Mint for the last fourteen years.

MR. DEHANE, F.R.C.S., of Wolverhampton, expired from heart disease on the 8th September, after a useful career of forty-three years in practice. He was Surgeon to the Infirmary, and held other appointments.

AT the Lyons University last week a Madlle. Caroline Sibert, of Vienne on the Rhône, took a Bachelor of Arts degree. Out of a list of twenty-two candidates this young lady came out first in French and Latin composition, and second in Latin translation.

DR. F. W. GIBSON, formerly senior Resident Medical Officer at St. Pancras Parochial Infirmary, died on the 24th June, on board ship. He had set sail in hopes of restoring his health, which was shattered by his devotion to his duties at St. Pancras.

THE *Indian Daily News* says, "An annual loss of revenue of sixty lakhs of rupees is entailed on Government by the smuggling of Malwa opium. The Government of Bombay is about strengthening its preventive police on the Kattywar Coast, to stop the export of smuggled opium."

A PARIS letter says that three female doctors—one French, one Russian, and the other American—have just passed successful examinations before the Faculty of Medicine. The American lady was the most brilliant of all, and astonished her judges by her profound knowledge of anatomy, dissection, pathology, and hospital practice.

ORDERS have been issued by the Indian Government directing that whenever cholera assumes an epidemic form in the bazaars of Indian military cantonments a temporary hospital is to be erected in the outskirts of the cantonments, where, as far as possible, all cases among natives are to be treated, the necessary establishment being entertained for the purpose, and kept up as long as the epidemic lasts.

PROFESSIONAL visitors of all nations to the Medical Congress of Florence, which began its sittings on the 20th inst., will, on leaving that city by any railway, have the privilege of travelling free to the utmost limit of the kingdom, and of a free passage from the coast to any kingdom in Europe by any Italian steamer. This graceful compliment of the Italian Government has just been intimated to the public journals by Dr. Bos, the Florence member of the committee.

THE Street Commissioner of New York has announced an intention to enforce strictly the following ordinance:

"No person shall place or post, or cause or permit to be placed or posted, in any street in the City of New York, any hand-bills or advertisement giving notice of any person having or professing to have skill in the treatment of any disorder or disease, or giving notice of the sale, or exposure to sale, of any nostrum or medicine, under the penalty of twenty-five dollars for every such offence."

The enforcement of such a measure as this would be of great value in stamping out quackery in this country.

EXTERN MATERNITIES AND LYING-IN HOSPITALS.

A REPLY TO CRITICISMS ON A COMMUNICATION TO THE DUBLIN OBSTETRICAL SOCIETY.

By EVORY KENNEDY, M.D., F.K.Q.C.P.

(Continued from page 215.)

Sir, in my ignorance I had imagined that in a large mass of calculations such as the preparation of my paper necessarily involved, errors in transcription and typography, and even oversights in calculation, might be expected to creep in. I further imagined that in a discussion for the benefit of science and humanity, such as this purports to be, an honourable seeker of truth would have shrunk from making use of such accidental oversights as weapons with which to damage his opponent. However, I have lived to learn. But, Sir, I am too old to learn much. Therefore I cannot undertake to benefit to the full extent intended by the lessons I have had in arithmetic.

Be that as it may, I may say this much, that should I be required to advise a course of education to qualify a man for a similar encounter to that in which I have been engaged, I should be disposed to take a lesson from the schooling I have had, and advise his being educated upon the excellent system so admirably laid down by Mrs. Malaprop, and which you, no doubt, recollect she so judiciously insists upon in allusion to her female pupil. "I should not allow her to meddle with logic, algebra, simony, fluxions, paradoxes, or such inflammatory branches of learning; neither should I let her trouble herself with mathematical, astronomical, or diabolical instruments. But she should be taught a supercilious knowledge of accounts; sent to school to learn a little ingenuity and artifice, and as she grew up she should be instructed in geometry, that she might know something of contagious countries, but, above all, she must be a true master of orthodoxy, in order that she may not pronounce her words so shamefully as people usually do, and that people may reprehend the meaning of what she was saying."

The pleasing duty now devolves upon me of commenting on my friend Dr. Beatty's paper, which I look upon as one of the most valuable read to the Society throughout this debate. He took up one idea, he never lost sight of it throughout, and he exhausted it so completely that every commentator who has dealt with his subject has been feeble in comparison to him upon it; I allude to the identity of puerperal fever and erysipelas. His arguments, cases, and reasoning leave nothing to be said upon this subject, if, indeed, further evidence was required to confirm the views propounded by Dr. Sidey thirty years ago, and sustained by almost every hospital physician who had possessed an opportunity of observing upon those diseases since. Dr. Beatty is equally strong upon the contagious nature of this, according to him, common disease, erysipelas and puerperal fever, and his observations upon this

branch of his subject merit our deepest attention. In fact, Dr. Beatty's support of my views is conclusive, and merits my warmest acknowledgment. Nevertheless, it was necessary that he should also attack me; but I am puzzled to know why he of all my commentators, should have been the person to read me and this Society a lecture upon the waste of time occupied in vain attempts to discover the nature, origin, and best means of preventing metria, and to prohibit speculation on the origin and common nature of zymotic poisons, in the very same breath that he advocates and insists upon the identity of two of these poisons, erysipelas and puerperal fever. Dr. Beatty asks this Society, in his own innocent manner, if any one is a bit the wiser after reading a passage which illustrates common poison on the principles of isomerism, as advocated by Dumas, for ignorance of which and its application to the subject in hand, any enlightened physician might justly have been condemned.

Dr. Beatty brings a charge against this Society of "one-sidedness" as applicable to their recent proceedings, their speeches, and their arguments in contravention of my paper." This is his language, not mine. Sir, I should have scorned to bring such a charge against our common profession, whatever insinuations Dr. Beatty, or even the all-powerful press of this country, may make to the contrary. Well may his congeners say—had an enemy done this thing, but that it should have been done by our own familiar friend with whom we had taken sweet council together; and he adds, that not one single voice has been raised in favour of my paper. Why, Sir, Dr. Beatty himself is a living instance to the contrary; his facts, his arguments, and his reasoning go most strongly in favour of my positions. I could not have wished for a better advocate, or more conclusive evidence than he adduces for my views—and he possesses this great merit that he is perfectly unbiassed towards me. I can, therefore, only explain the hostile line he has taken by his labouring under this strange hallucination that all the speakers on my paper are "one-sided," and conclude, that his national tendencies so predominate that he must strike a blow on the one side even whilst his arguments go to support the other, on what he so naively designated this "one-sided discussion."

Dr. Beatty sets out by another rather sly cut at his friends in telling them that *their statistics have so well answered the purpose for which they were used*, that he will not weary the Society by any allusion to that dry subject, further than by giving a table of his father, the late Dr. John Beatty, and his own statistics in private practice. Their total combined deliveries were 7,680; deaths, 30; being a mortality of 1 in 256. I believe this death-rate to approximate much more nearly to the true general rate in private practice than the examples given in Dr. M'Clintock's or Dr. Churchill's tables.

I, therefore, accept them as far as they go as confirmatory of my views and calculations.

Dr. Beatty then passes to the support of my views upon a common poison, and succeeds in establishing the identity of two at least, indeed I might say three, ranking pyemia as one. This is a first step towards the accomplishment of what may eventuate as a more general recognition of this principle. He modifies this statement when he says we know that zymotic diseases, but more especially measles and small-pox, are not convertible the one into the other. But, it will be in the recollection of the Society, that Dr. Stokes met this difficulty by admitting the occurrence of *mule diseases*; therefore, on these nicer points, we may safely leave Dr. Beatty and Dr. Stokes to fight it out.

I might here take an exception to the pathology of Dr. Sidey and Dr. Beatty, and state that the great variety of tissues engaged, and the not infrequent absence of peritonitis, and other serious inflammations, in metria, do not quite justify the con-

clusions that "puerperal fever is merely an erysipelatous inflammation of the peritoneal covering of the pelvic region, or other serous membrane, extending, as the disease advances, over the abdominal cavity, and the body of the uterus accompanied by true erysipelatous fever." Dr. Beatty says that when erysipelas is epidemic, metria is sure to appear, and that when erysipelas subsides so will metria, "if separation for a time be enforced, and the disease not perpetuated by contagion."

This latter admission is valuable, and the Society should not allow it to escape their notice, that on Dr. Beatty's authority, the condition upon which this common disease subsides is separation, which condition not being complied with, it does not subside. Could this gentleman have used a stronger argument in favour of isolation and the establishment of cottage hospitals? I think not.

Dr. Beatty next attacks my statement, that metria approaches more nearly to a constant quantity in great lying-in hospitals; and asks me why it is not always present in such institutions? and why it is more intense when the greatest numbers are collected together? which he answers is notoriously not the case.

Now, Sir, is it really necessary for me, with the statistics of all the great hospitals of Europe before you, and with those of your own hospital at your door, to go back and prove to this Society what Dr. McClintock has denominated, "the great excess of metria cases in hospital?" If language expresses facts, or facts are capable of expression by language, what language could more accurately express this state of facts than that metria approaches more nearly to a constant quantity in a great hospital? But, indeed, the tenor of Dr. Beatty's own paper goes to prove this, although he explains the excess of metria on different grounds.

I may here mention, in addition to the dread array furnished in my former paper, that in the Maternity at Turin, where 700 or 800 women are annually delivered, the mortality for the last ten years amounted, according to Professor Faye, to 1 in 25, or 4 per cent. in the students' department. In the department for midwives it is said to be still greater, which fact, together with the more recent experience of the Vienna hospital, would appear to lead to the conclusion that too much stress may have been laid upon the extension of contagion through dissections. However, as this is a step in the right direction, we shall not dwell upon it.

In the lying-in hospital in Dresden the average mortality amounts to 2 to 3 per cent.

The lying-in institution in Copenhagen, according to Dr. Stadfeldt's report, gives 1,237 deliveries in the year, with 41 deaths, 1 in 30, or 3.3 per cent. This approaches very near to the mortality in the Dublin Lying-in Hospital as it does in the number of deliveries. This report, however, is stated to be, on the whole, more unfavourable than that of the preceding year.—*Med. Chir. Rev.*, Jan. 39? T. 26?

(To be continued.)

VACCINATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The *vox et præterea nihil* discussion, occupying the pages of the *Pall Mall Gazette* and *Lancet*, respecting the exhausted subject of vaccination, having evidently a *Jenner redivivus* in the Editor of the latter journal, that gentleman might have summed up his replies in answer to the *Pall Mall*, by quoting the case of the Yankee, who had no sympathy with Public Vaccinators, "I don't believe it's any use, this vaccination," said the American, "I had a child vaccinated, and he fell out of a window a week after and got killed." Four columns of a leading article in the *Lancet* amounts to this, "to the withering of the children!" operated on.

Yours, &c.,
CROM A BOO.

RETENTION OF URINE.

Dr. J. H. Curtis, of Kansas City, Mo., relates the following singular case in the *Chicago Med. Examiner*:—

Kate H., 14 years of age, lives near Wyandott, Kansas; brought to the office September 3, 1868; has pale, sallow complexion; tongue pale, flabby, and heavily coated; pulse regular, and not too rapid; abdomen but very little enlarged, and without tympanitis, and without tenderness or pain. But complains of some pain, with a curious feeling in head; has never menstruated; bowels regular, but without any desire to micturate. There is a very considerable increase of size about the pelvic region, with a spreading of the hips like a woman in the last stage of pregnancy, but without any evidence of dropsical effusion, either in the cavities or cellular tissues. Declares positively she has not voided a drop of urine for four weeks and four days; her statement is corroborated by her mother, who has been with her constantly, watching her closely when she would go out to stool, and asserts it has been absolutely impossible for her to have passed any urine without her knowing it; and for thirty-two days not one drop of water had passed from her as urine. Has been under treatment a number of weeks from three or four doctors in their neighbourhood, but without any benefit; catheterism having been tried twice without any result.

I gave her immediately fl. ex. hydrangea, ʒiiss., to be repeated every three hours, and to be followed in one and a-half hour with a powder of calomel, grs. xx., to be repeated at the same intervals after each dose of the hydrangea, until the bowels should be well moved. In fourteen hours after she had taken five doses of the fl. ex. and four powders, and before the bowels had moved, after suffering the most intense pain for an hour previous, she passed three and a-half quarts of very clear, colourless urine; the bowels were well moved in an hour or two afterwards, and in six hours she again voided four quarts more of the pellucid-looking water, by which she was entirely relieved. In two weeks complete convalescence was established, by the use of pil. hydrarg. every third night, and the use of nit. potass. and soda bicarb. solution every three hours during the daytime.

THE INFLUENCE OF COLD, IN PREVENTING THE ANÆSTHETIC EFFECT OF CHLOROFORM.

WHEN administering chloroform, whether in hospital or private houses, one seldom has to take into account, in any great degree, the subject of *temperature*; and it is generally overlooked that chloroform acts very imperfectly when inhaled in a temperature below 65° F. Some of the other anæsthetics, I believe, as bichloride of methylene, have effect at somewhat lower temperatures, but none of them will produce insensibility in a very cold atmosphere.

This property of chloroform was very practically forced on my notice last year in Ladak. In the month of May, when the thermometer never rose above 45° F. in the shade, I was operating for the removal of some stumps of fingers from a man whose hand had been severely frost bitten. The operation was performed under the shade of a tree, where the air was warmer than in the house, and the thermometer stood at 45°. I first attempted to produce anæsthesia by chloroform, and having warmed the bottle, gave it in the usual way, on a handkerchief, but without any effect whatever being produced, although more than one ounce was administered. I noticed that the chloroform had hardly any smell when poured out, at the same time it evaporated rapidly enough; not even intoxication was produced, and I had to perform the operation when the man was fully conscious. I was partly under the impression at the time that the chloroform was bad, especially as it had been previously warmed, or else that the man was constitutionally insusceptible to its effects. A few weeks afterwards, however, when the temperature (in the tent where I operated) was over 70° F, I again administered the *same* chloroform to the *same* patient for a corresponding operation on his other hand, and insensibility was produced rapidly and completely, thus proving that the failure on the previous occasion was due to the coldness of the air. This fact is worth noting by any one likely to be called on to perform operations in a cold climate, where there are no conveniences for producing artificial warmth as in hospitals, &c., in civilised countries.—*Dr. Cayley, in Indian Medical Gazette.*

DANGER OF GIVING STRONG DOSES OF CAMPHOR.

A case illustrating the above has recently been brought under the notice of the Société de Médecine et de Pharmacie de Grenoble. An enema consisting of five grammes of camphor dissolved in the yolk of an egg, was given to a child three years of age, suffering from typhoid fever. Symptoms of poisoning at once manifested themselves; convulsions, lividity of the countenance, stupor, arrest of the urinary secretion, &c. The employment of coffee sufficed to restore the child.

Medical News.

THE Military Secretary, India Office, presents his compliments to the Editor of the MEDICAL PRESS AND CIRCULAR, and begs to enclose a list of the Candidates for Her Majesty's Indian Medical Service, who were successful at the competitive examination at Chelsea in February 1869, and who have undergone a course of instruction at the Army Medical School, together with the total number of marks obtained at the examinations at Chelsea and at Netley.

India Office: September 8, 1869.

C. W. Calthrop, London, 5753 (obtained the Herbert Prize*); A. Wood, Aberdeen, 5,668; R. C. Sanders, London, 5,455; E. Sanders, London, 5,015; B. Franklin, London, 4,895; F. P. Edis, London, 4,888; R. T. Wright, Edinburgh and London, 4,886; G. McE. Davis, Ireland, 4,856; K. P. Gupta, Edinburgh, 4,863; J. A. Howell, London, 4,501; H. J. Linton, Edinburgh and London, 4,253; C. T. Peters, Edinburgh, 4,177; H. P. Roberts, Edinburgh, 4,138; G. Colson, London, 4,070; C. W. Mockery, Edinburgh, 4,025; M. E. Murphy, Ireland and Edinburgh, 4,021; W. Price, Ireland, 3,938; S. M. Tyrrel, Edinburgh, 3,921; W. H. Booth, London and Glasgow, 3,863; J. Backhouse, Ireland, 3,703.

* Maximum number of marks, 6,900.

PAUPERISM.—The return of the Poor Law Board shows that in the first week of September there were 128,344 paupers in the metropolis, in the proportion of 95,101 indoor to 33,243 outdoor. This was a decrease of 182 on the figures of the corresponding week last year.

NOTICES TO CORRESPONDENTS.

In all cases when proofs are sent, it is of the utmost importance for them to be immediately returned.

CORRESPONDENTS not answered should look to the answers the following week.

TO SUBSCRIBERS.—Those gentlemen who have not paid their subscriptions for last year are respectfully reminded of the omission.

M. D. M. R. C. P.—The wealthy man who offered you four guineas for your services must be an unusually shabby fellow. Your M. R. C. P. does not, since the Medical Act 1868, prevent you suing for your bill. It is only the Fellowship which can be pleaded in bar. It is, therefore, open to you to enter an action and produce evidence of the value of your professional services and the usual rate of remuneration. A guinea per mile is the old fee, and many London physicians still exact it. For long journeys the majority now take less, and £2 2s. for three miles is a common fee. With railway facilities half a guinea a mile might be as much as would be allowed. Apart from such an action you are at the mercy of a mean man. It is the penalty of your respectability.

LARGE FAMILIES.—W. C. draws our attention to the following extract from the letter of a clerical correspondent in a daily paper, and says: "After all, are the late doctrines really so diabolical as some people assume." "A word to the 'Old Clerk' who comes forward with the fact of his family being eleven in number. If this means he has nine children, I have no respect for him. He knew what his income was and would be. What right—I boldly say—what right had he to have so many olive branches, and then come moaning as though they had been forced upon him? A man who brings himself to poverty through idleness is justly reprobated—why not one who chooses to have his quiver full of arrows which must be useless, as he can neither start them off nor give them feathers to direct their flight, nor yet tip them to make them of service. I beg to refer him and others who plead for charity on the strength of a large family to 'Mill's Political Economy,' People's Edition, Book II., chap. XIII."

Deaths.

BURKE.—On the 21st ult., at Hermitage Villas, Richmond Surrey, Juliana, the wife of Joseph Burke, Esq., Deputy Inspector-General of Hospitals.

CHRISTIE.—On the 7th inst., John Christie, M.D., F.R.C.S.Ed., of Union street, Aberdeen, aged 51.

DEHAENE.—On the 8th inst., suddenly, at Wolverhampton, Edward Francis Dehaene, F.R.C.S.E., aged 61.

GIBSON.—On the 21th of June, on his voyage to Australia, for the benefit of his health, F. W. Gibson, M.D., late Senior Resident Medical Officer of St. Pauers Workhouse Infirmary, aged 33.

GRAUD.—On the 4th inst., at Faversham, Mary, widow of Frederick Francis Graud, Surgeon, aged 58.

GRAVES.—On the 8th inst., at Stretford road, Manchester. George Graves, M.R.C.S., L.S.A., aged 63.

GROVES.—On the 4th inst., at Lincoln, Edward Keet, the son of Edward Graves, L.R.C.P., M.R.C.S., L.M., aged 3 weeks.

SPURGIN.—On the 1st inst., at Sidmouth Villa, New road, Hammer-smith, Emily Sidney Spurgin, aged 10 days.

ON PAIN AT THE HEART AND IN ITS NEIGHBOURHOOD—CASES AND APHORISMS.

By HORACE DOBELL, M.D.,

Senior Physician to the Royal Hospital for Diseases of the Chest, &c.

(Continued from page 116.)

In my last paper I concluded with this aphorism, "The conjunction of pain at the heart and pain in the left arm is a most important symptom of heart disease, and is never to be disregarded." This is illustrated by the following cases.

CASE 7.—John R., æt. forty, ill two years. Two years ago first felt a sense of direct pressure on the epigastrium (not under the nipple) on taking exercise, but not after food. Cessation of exercise for a few minutes removed the pain. But the pain has been gradually getting more severe and more easily produced ever since. During the last ten months food as well as exercise has brought on the pain, and now either food or exercise bring on, also, pain and numbness of the left arm, and of the thumb, and all the fingers of the left side, lasting about an hour after food, but more severe in character after exercise than after food. Has frequent attacks of hard throbbing palpitation of the heart. He cannot now walk a hundred yards without pain; but five minutes' rest will take off the chief distress. After a glass of hot water can walk further without pain, and anything which expels wind always gives relief. During the pain, feels great languor, but no vertigo. While the numbness lasts, the hand and arm are dead white. For several months, about eight months ago, the left leg used to get partly numb at the same time as the hand. Never had rheumatic fever or any other illness except inflammation of the bowels in childhood, and sixteen years ago slight pains in the arms, possibly rheumatic. Sallow complexion, pale mucous membrane. Pulse

70, regular, both sides alike, soft, jerking, without *vis a tergo*. Heart's dullness normal, impulse strong between fifth and sixth ribs. First sound accompanies impulse and is normal; immediately followed by a long, soft, rather high-pitched, blowing bruit, replacing the short pause and the second sound, heard in greatest intensity at the base, also heard up to both right and left clavicles. At the base nothing is heard but the systolic sound and this long bruit; but at apex a separate much less distinct bruit immediately precedes the systolic sound. Blisters to the epigastrium, powder of soda, ginger, and calumba before food, abstinence from malt liquor and cheese; rest. After three weeks, pain not now produced by food if he remains quiet; but directly he walks the old pains come on, only with this alteration, that they are less felt at the epigastrium and more under the left breast.

This patient was watched for six months, and a variety of treatment directed to his heart symptoms. He was much benefited by losing the dyspeptic complication, so that his distress was no longer produced by anything but exercise, and he said he was as well in health as he ever was in his life. But his physical signs remained the same, and the slightest exertion brought on the pain at the heart and down the left arm, with palpitation and short breath.

CASE 8.—Frederick E., thirty, ill twelve months. Pain of aching character in the middle of the sternum, above the level of the nipples, produced by exercise. If the exercise is continued pain goes down both arms to the wrists, but never to the fingers. If exercise is still further continued, pain gets worse and worse in both chest and arms till he is obliged to stop. After a few minutes' rest the pain goes, but returns as before with renewed attempts at exercise. These symptoms have been coming on twelve months from no assignable cause, except overwork. Taking food does not affect the pain, and never produces it. Never had rheumatic fever. Pulse the same on both sides, resistance very deficient. Heart's impulse strong, and diffused widely. Slight but decided increase of cardiac dullness above, and to the right, at the line of the nipples, dullness extends over the mesial line. First sound loud, no bruit, base or apex; second sound loud, and at base, down mid sternum, and up to right and left of base,

but not at apex, a peculiar "cluck" is heard at the end of the sound, giving the impression of a small jet of fluid jerked through an opening. He was sent home in a cab, and ordered to be kept perfectly quiet for a week—on no account to do anything which excited pain—and to be brought in a cab for fresh examination at the end of the time. It was afterwards ascertained that instead of obeying these orders, on the day after his visit to the hospital he walked, with great difficulty, from Islington to Parliament-street, Westminster, at the corner of which he dropped down dead, and that those who saw him fall said he was "dead at once." No further information.

CASE 9.—Mary P., forty-one, married; ill, more or less, two years. Had rheumatic fever fourteen years ago. Pain at the heart, and *in the left shoulder, and down the left arm to the elbow, and to the little and ring fingers* whenever the heart palpitates—that is when she is flurried, or ascends, or hurries; not produced by food. When the pain comes she turns giddy. Sleeps heavily, without pain or distress. Loud diastolic bruit at apex. First sound clear of bruit, but feeble; second sound at base, very loud and clear. Ordered rest.

CASE 10.—Henry L., fifty-five; ill, more or less, eight years; worse of late. For eight years subject to dull pains over lower part of sternum, extending across chest, and accompanied by *numbness of both arms*. The pain begins a quarter of an hour after food, and is relieved by eructation; no cough, but some dyspnoea on exertion, and on taking exercise, a pain comes in the centre of the lower third of the sternum, and both ascends and descends from this spot *affecting the arms*, and if exercise is continued the oppressive pain goes down the abdomen in the direction of the large vessels. He cannot walk five minutes without the pain coming in the sternum; if he then rests he can go on without pain so long as he walks very quietly, but if he hurries, the pain returns and stops him as at first. Had rheumatic fever four years ago—no other history. Cardiac dulness at fourth costal cartilage extends a little over mesial line to right. A very soft low-pitched systolic bruit, heard most distinctly in the centre of sternum between the fourth costal cartilages, descends a little to the right, fades away on ascending. Powder of ginger, calumba, and soda, blue pill, and compound rhubarb occasionally, iron and quinine daily; rest. After four weeks, no pain from any cause but exercise; after eight weeks the pain ceased to extend into the abdomen, and he had learnt to manage himself so as to return to his business, and to take exercise moderately without pain; but any attempt to hurry or push on, when pain threatened, still produced it.

In all of these cases the physical signs show the existence of incurable organic disease. The principal points of practical interest are as follows.

(To be continued.)

ON THE USE OF CARBOLIC ACID IN THE TREATMENT OF DIPHTHERIA.

By WILLIAM WAUGH LEEPER, M.D., Loughgall.

IN the month of July of this year the district of which I have medical charge was visited with diphtheria. Six years ago a similar visitation occurred here, and several children, and even one grown person, died from the disease. I was very apprehensive of a similar result this year, and the first case was so severe and so rapidly fatal that I had the greater cause to be in dread of a like result. Early in July I was asked to see a little girl, aged six, whose parents told me the child had been ailing two days, but that they did not know what was the disease farther than there was some swelling of the neck. On my arrival at their house I found the little patient almost moribund. The face was pale, and the lips of a livid hue; there was some difficulty of breathing; the nasal passages were obstructed by dark-coloured discharges, and the inside of the throat was covered with the same greyish, pulpy-like

exudation; and the breath had a most offensive gangrenous smell. I had no hope to offer the afflicted parents. The child fell rapidly into a state of stupor, and died in a state of *prostration* two hours after my visit. I felt greatly disheartened by this first case, and dreaded I should have to deal with other cases of this terrible malady. I had not long to wait. In the same house, out of a family of five girls, four became affected; but fortunately every case was mild, and each terminated favourably.

The treatment in each case was supporting from the first, giving beef-tea and moderate quantities of wine, and a mixture consisting of tinct. ferri hyd., chlor. potassæ, syrup and water, &c., &c.; and touched the tonsils and parts on which there appeared any exudation with *sulphurous acid*, mixed with seven parts of glycerine. I conceived that in this treatment I had discovered a valuable, if not a certain remedy; but the next case disproved my idea. The case was as follows, and occurred in the week following the foregoing cases, and in the house of one of the first families in the county:—

M. C. was seized with pain in the throat and difficulty of swallowing on the 16th July. When I saw her, on the following day, there was sub-maxillary enlargement; a feeling of much depression; the tonsils and pharynx were red and dry, and on the left tonsil was a filmy patch of a whitish gray colour, as large as a fourpenny piece, which I at once recognized as the beginning of diphtheritic exudation. I had my patient put to bed, so as to preserve her from chills and to conserve strength, and commenced with the iron and chl. pot. mixture, and touched the spot with the sulphurous acid solution in the following strength: one drachm of the acid, and five drachms of glycerine.

On my next visit the false membrane, which I thought had been destroyed on the tonsil, had reappeared, and covered not only it, but the other tonsil and a small portion on the back of the pharynx. Again I applied the lotion, and just after the application I looked at the throat and conceived the whole false membrane was removed, as every part looked clean, though still red and inflamed.

Next day the appearance of the throat was *worse* than before. The whole of the tonsils and uvula, and, to some extent, the pharynx, were covered thickly with the ashy exudation. Fortunately, there were no croupy symptoms present, so I concluded the disease had not as yet invaded the larynx. I now lost faith in the *sulphurous acid* application, and, as I never found any benefit from the nitrate of silver in these cases, I applied a lotion freely, consisting of—*glacial carbolic acid*, one part; glycerine, six parts; and ordered a gargle of carbolic acid (one to twenty) to be used frequently, and assiduously continued the nourishment, beef-tea, champagne, ice, &c.

At the next day visit the appearances in the throat were more favourable, though the general symptoms were worse. The tonsils were free of the exudation, but it still existed on the velum and pharynx.

There now existed extreme prostration; the face pale, and the pulse very quick and feeble; and during the night there had been bleeding from the nose. There was also some excoriation at the ali nasæ; the urine was albuminous. I reapplied the carbolic lotion, directing the sponge above and behind the velum, and increased the nourishment by the "*brandy and egg mixture*." During the next twenty-four hours I remained in dread of a fatal collapse, the little one's strength seemed so entirely gone. Her feet were cold, and the pulse scarcely to be felt. We persevered, however, assiduously with nourishment, and she submitted willingly to another swabbing with the carbolic solution. From this time (the sixth day of the disease) the cloud of danger began to disperse. The membranous exudation was no longer reproduced, and the swelling at the sides of the jaws began to disperse; the countenance became more animated, and the extremities warm, and she took her nourishment well. Suffice it to

say that she slowly and steadily recovered, and is now quite well.

This was the first case in which I used the *carbolic acid* treatment. I have used the same in four more cases, and in each it has proved, to my judgment, a valuable remedy. I shall not relate in detail all these last cases, as they were all very similar, excepting one, to that of Miss M. C., and have terminated in recovery. The last of the four cases to which I have now alluded was, indeed, by far the most severe and most alarming of any, and only a few days ago I was able to pronounce my patient out of all danger.

In the last week of August, Andrew Wallace contracted diphtheria from his little son and daughter, both of whom had died of the disease a few days before without any medical man being in attendance. The family did not suspect the nature of the ailment which had invaded their clean cottage, but when the second child was dying they sent for me, too late to do anything to save its life; but the father, a man over sixty years of age, was ill. I directed my treatment to his case. He had, at first sight, all the appearance of a man in typhus fever; but on examining him carefully I discovered that his throat was what he complained most of. A white diphtheritic exudation existed on each tonsil. I ordered the mur. tinct. of iron and chlor. pot. mixture, and began the carbolic acid swabbing, also nourishment consisting of the very best beef tea, the egg mixture, &c. The disease invaded the *whole throat, tonsils, velum, roof of the mouth and gums*. Night and morning I visited this sad case, and most thoroughly applied the carbolic acid lotion.

At the end of the seventh day hiccough set in and diarrhoea, and the friends lost all hope; but a perseverance with the lotion and all the other remedies crowned our efforts. About the ninth or tenth day the throat was clean and the hiccough ceased.

From this period he steadily recovered, and is now (18th September) going about pretty well.

I had the advantage of showing this case to a medical friend, and he is convinced that this remedy has a decided effect in checking the reformation of this exudation. I ascribe to it in a large measure the recovery of Miss M. C., as, previous to using it, I had tried other agents, all of which proved futile to arrest the spread of the disease. I consider it a very valuable remedy used in conjunction with suitable internal treatment, and believe the strength in which I used the lotion just such as will destroy the tendency to fresh exudation. In two cases there existed a croupy cough and some dyspnoea, and yet, under the treatment above detailed, they got well, though I cannot be certain that any part of the lotion reached the larynx. The fits of suffocation were so severe in attempting to apply it that I always had to desist before I was satisfied that the sponge had come in contact with the laryngeal opening. I recommend a trial of this treatment by the profession. If by its aid we can arrest the exudation when commencing on the tonsils, uvula, or pharynx, we may succeed in some cases in preventing its spread to the more vital organ, the larynx, and so snatch some patients from the grasp of this terribly fatal disease. I say, if such a result can be reached in any case by this treatment, we shall have discovered a remedy of great value.

SURGICAL MEMORANDA.

By J. Waring Curran, L.K. & Q.C.P.I., L.R.C.S.I.

EXTENSIVE TUMOUR OF THE FACE.

THE rapid progress made in the practice of surgery in late years makes the case whose history I am about to relate exceptional, whilst it proves the importance of surgical interference at the right time, or the subsequent living disgrace apparent to every eye, professional or other-

wise, of the want of proper skill in the treatment of a simple disease, which must of necessity follow, that must be attributed to ignorance or to apathy, and but little calculated to add to the honour and credit of that branch of the Profession which, of all others, has advanced most in our own time.

A. B., the mother of a large and grown up family, about fifty-seven years of age, sought, a few years ago, the advice of a country surgeon regarding a small growth of a moveable nature, which she first remarked at the angle of the right jaw-bone. She was informed that it was an indurated gland; as such, I understand, it was treated. The health remained good, and the woman persisted with the remedies or nostrums for swollen glands, but the growth gradually increased, and the following illustration, which I have made from the patient before me, demonstrates the present state of matters.

The tumour—an irregular nodulated mass, with a feeling of elasticity, and upon poising it the impression that it must consist at least of twelve or thirteen pounds weight—extends behind the ear as high as the tip of its helix, engages the parotidæan and sub-maxillary spaces, passes forward under the inferior maxillary bone for three-quarters of an inch to the left of the symphysis menti, whilst the great mass or body of the tumour hangs down, resting on the right clavicle and the parts for four inches beneath it.

From the irritation of such a growth—a blot upon our art—the annoyance of such a weight, although suspended in a silken receptacle, the woman, to kill care, has become a confirmed opium eater or laudanum drinker. She is very much emaciated. This condition of system, combined with the extensive and deep-seated attachments of the tumour, render surgical interference at this stage out of the question. Accordingly, the best part of a life is made miserable, and a whole family wretched, which, so far as the growth was concerned, might have been very different had judicious and timely operative interference been had recourse to.

INTESTINAL OBSTRUCTION, PRODUCED BY A RENT IN THE GREAT OMENTUM, THROUGH WHICH A PORTION OF THE BOWEL SLIPPED, CAUSED BY THE FRIGHT OF A DOG.

Annie Sabin, twelve years of age, enjoying good health, was sent by her mother to carry her brother's dinner a short distance from their residence. In order to do so it was necessary that she should pass the house of a man who kept a ferocious dog, which was the terror of the village children. The child had passed the house when the dog ran out. She was very much frightened, and flew from the fierce animal a considerable distance, the dog following, but not succeeding in biting her or tearing her clothes. When in the act of running she felt a violent pain in the belly, and when

the dog ceased pursuing her trembled very much, vomited, and had her bowels relieved twice in rapid succession. This is an outline of the history obtained from the child's father, who came to fetch me.

Upon visiting my patient I found her lying on a sofa, suffering great pain, referred to the epigastrium, accompanied by constant vomiting and by depression. Upon careful examination, I could discover no hernia, nor other abnormal appearance. Accordingly, I directed warm fomentations to be applied, and to be frequently renewed, and prescribed an ordinary mixture to allay the sickness or control the vomiting.

August 5th.—The vomiting continues; the child suffers violent pain; the pulse, small and regular, is 132; and there has been no passage through the bowels since immediately after the fright. Directed that an aperient enema should be thrown up at once, and repeated if necessary in two hours.

Evening visit.—No fecal matter has come away with the enemata; the pain is not so constant, more of a colicky character; the vomiting, which continues, and is produced by the slightest movement or change in position, is of a greenish colour and watery character. There is great tenderness, the seat and extent of which is mapped by a circle with a radius of an inch and a quarter surrounding the umbilicus. Ordered the application of three leeches over the site of pain, and directed perseverance with the enemata.

6th.—There is no improvement, and the general symptoms are the same as upon yesterday. I suggest to the parents the advisability of operation, whilst I explain the hazardous nature of such a procedure; but they refuse consent to such a resource, even as a *dernier ressort*.

7th.—The vomiting has become stercoraceous, assuming a yellowish colour, with a most fetid odour; the pain is severe, and the seat of tenderness more extended. During a paroxysm of pain, the recti muscles stand out in rigid outline, but I am unable to detect any prominent portion of the bowel that might be constricted. I prescribe nutritive enemata of beef-tea, port wine, and cream, with ten drops of tincture of opium in each enema, and paint the belly with extract of belladonna rubbed down in glycerine.

8th.—There is great feebleness, the pulse running at 140. The belladonna locally applied affords relief, in addition to which I direct a suppository, containing half a grain of opium, to be passed up the rectum twice a day.

9th, 10th, 11th, and 12th.—Patient continues much in the same condition, and is kept alive by enemata.

13th.—The pain is less severe, but the tenderness more diffused. The fœtor from the vomiting is such that the people can scarcely remain in the house. There is hicough, the face is pinched, and the pulse is scarcely to be felt. However, in this condition she lived. The suffering alleviated by opiate suppositories and the local application of belladonna, and strength sustained by the most nutritious of enemata until the 20th, when dissolution came to the release of the patient, and the relief of all about her.

Autopsy.—Thirty-six hours after death I made a *post-mortem* examination. Upon opening the abdomen, a quantity of fluid escaped. What forced itself upon us was a rent in the great omentum behind the umbilicus, with a good sized knuckle of intestine protruding, which was in a gangrenous condition. The opening was circular, and bound the intestine like a bony ring, but such a stricture as operation would have proved most successful in relieving, and, most probably, in permanently curing; however, this was only to be detected after death. Nevertheless, the operation would have been performed by me had the parents given consent. There was also general peritonitis.

At a coroner's inquest subsequently held, it was proven by witnesses that the dog which frightened the child was a most ferocious beast, having caught, shortly before the present accident, one of the witnesses by the throat; but, as the Coroner directed the case to be brought into another court after the verdict of the jury, I forbear commenting on the legal bearings of the case.

Hospital Reports.

CLINICAL RECORDS FROM THE DUBLIN HOSPITALS.

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.

A RECENT CASE OF LATERAL LITHOTOMY.

By Mr. ROBERT ST. JOHN MAYNE.

WILLIAM JOSEPH PENROSE, aged four years and nine months, first came under my observation early in last July, at which time his condition was the following:—He suffered great pain during and for some time after micturition, which took place almost every hour, and the call for which he could not for a moment resist.

The urine, which usually flowed in a good round stream, at times became most unexpectedly arrested, and again as suddenly re-appeared upon a change of position, or a slight alteration in the attitude of the body. He experienced considerable uneasiness referrible to the extremity of the glans penis, at which he pulled so continually that the prepuce had become elongated, and the index finger and thumb of the right hand were perceptibly soddened. He laboured also under prolapsus of the anus, accompanied by paroxysms of the most distressing tenesmus. As these symptoms naturally pointed to the existence of stone in the bladder, it was determined to sound, and an instrument was accordingly introduced. On the interior of the cavity being carefully explored, a calculus was detected lying, not in the ordinary situation (at the inferior part), but behind the pubis, a site most unusual in so young a subject, and one in which it was thought to be fixed. According to the most careful measurement, its size was estimated at that of a marble, but owing to the very small proportions of the viscus, such examinations were necessarily conducted with the greatest difficulty. The patient was admitted into the Meath Hospital upon the 4th of August, and on the morning of the 9th, having first had his bowels well cleared out by an enema, he was brought under the influence of chloroform, and firmly secured in the lithotomy position. The staff, laterally grooved, and not upon the convexity, as is usually the case, was introduced and held by my colleague, Mr. Wharton, well drawn up under the pubis. By this proceeding, considerable space was obtained, and the urethra was removed as far as possible from the vicinity of the rectum—a matter of great importance where the parts were so very diminutive. At this juncture, the urine escaped by the side of the staff, a circumstance which caused considerable embarrassment at a subsequent stage of the operation.

The first incision was commenced on the raphe of the perineum, midway between the scrotum and anus, and was carried downwards and backwards, increasing in depth as it advanced, to a point between the anus and tuberosity of the ischium, but somewhat nearer the latter and well *beyond both*. Upon the latter point I wish to lay particular stress, as I consider that thus the greatest room can be obtained at the least risk of injury to the patient.

The intervening structures having been divided by a few touches of the knife, the groove in the staff was sought for and distinctly felt, but, owing to its position (*viz.*, upon the side of the staff), some difficulty was experienced in fixing into it the point of the finger-nail. After a slight delay this obstacle was overcome, and the knife, firmly pressed into the groove, was steadily thrust onwards towards the bladder. Here, however, arose the most trying part of the operation, for, during the introduction of the staff as above mentioned, the urine had entirely escaped by its side, and the little viscus having completely collapsed, and constantly retreating before the finger, rendered its entrance exceedingly difficult. The absence also of the

gush of urine, so reassuring and encouraging to the operator, naturally tended to increase the uncertainty of the moment.

Under these circumstances I requested my colleague, Mr. Porter, to explore the wound, and he having agreed with me that the deep incision should be extended, this was done, and the interior of the bladder at length reached. The staff was now withdrawn, and the stone having been discovered behind the pubis, as anticipated, was from thence readily hooked down by the finger. The remaining steps of the operation were speedily performed; viz., the gorget was introduced, and through it, as a director, the closed forceps, care being taken not to divaricate the blades of the latter (lest the mucous membrane should be entangled), until the stone was distinctly felt. In this no difficulty was experienced, and the extraction was effected with the greatest facility of an oval calculus, weighing $35\frac{1}{2}$ grs., and measuring in its long diameter about three quarters of an inch, and half an inch transversely. The microscope revealed its exterior to be composed of prisms of triple phosphate.

A canule *à chemise* having been placed in the bladder, the child was removed to bed. After thirty hours this was withdrawn, as the surface of the wound had now become sufficiently glazed. The urine continued to flow through the perinæum for six days; upon the seventh morning, however, it for the first time appeared by the urethra, gradually relinquishing the abnormal course until the tenth day, from which time micturition was perfectly performed by the regular channel. The patient left the hospital quite recovered upon the 21st day.

Subjoined are three analyses of the urine, for which I am indebted to my friend, Dr. J. W. Moore. The first, made before the operation, shows the condition of that fluid uninfluenced by the operative proceedings. The second and third exhibit the modifications produced by the presence of the inflammatory process.

Analysis No. 1.—August 7th, 1869.

Urine pale, slightly opaque, faintly acid. No albumen, no sugar. Not a sufficient quantity to ascertain spec. grav.

Microscopic examination reveals the presence of epithelium, mucus, and amorphous phosphate of lime. After standing for forty-eight hours, prisms of triple phosphate formed.

Analysis No. 2.—August 19th, 1869.

Urine pale, turbid, alkaline. Spec. grav. 1010; contains a considerable quantity of albumen. Urea obtained as nitrate on concentration to one-third, therefore in fair proportion to the density. Deposits phosphates in abundance.

Microscope :—A viscid mass, thrown down on standing, is found to consist of many prisms of triple phosphate, amorphous and crystalline phosphate of lime, mucus, a large quantity of pus, and some epithelium.

Analysis No. 3.—August 26th, 1869.

Urine faintly acid, pale, and slightly turbid. Spec. grav. 1019; contains a good deal of albumen, no sugar.

Pus present, a rosy mass being formed on adding an alkaline fluid. In eighteen hours the urine had become strongly alkaline, an iridescent film had formed on the surface, and a white glairy deposit had fallen down.

The film, when examined under the microscope, was found to be composed of prisms of triple phosphate, and spherules of urate of soda. The deposit contained vibrations, urate of soda spherules, prisms of triple phosphate, pus, mucus, and epithelium.

Upon a careful consideration of the circumstances above recorded, I am inclined to think that the difficulties incidental to lithotomy are greatly augmented by using a staff grooved upon the side. There is more uncertainty in ascertaining the exact situation of the groove, and from the cramped position in which the guiding finger is unavoidably placed, a considerable loss of steadiness must invariably ensue. In striking, moreover, the staff (which should be

done as vertically and as far backwards as possible, so as to get behind the base of the triangular ligament, and thus to avoid the artery of the bulb), the groove may be entirely missed, or, having been successfully entered, may be subsequently lost, in consequence of the knife's point not being as securely fixed as by the staff grooved upon the convexity. The only real advantage to be derived from this method is the safe and sufficient amount of lateralization that the blade necessarily experiences in the procedure.

REMOVAL OF ADENOID TUMOURS IN AXILLA.

Under the care of Mr. WHARTON.

On the 30th of July, Mr. Wharton removed from the axilla of an otherwise healthy woman, aged twenty-four years, a number of tumours, which microscopic examination afterwards showed to be of the adenoid variety.

The patient had been married for about five years, and was the mother of three children, the youngest twelve months old. She always enjoyed good health up to the period of her first confinement, when she suffered from an abscess in her left breast. Shortly afterwards, about three years previous to her admission, she perceived a swelling in the left axilla, which continued gradually and painlessly to increase up to the period of her entering the hospital. The mass, which, except from its size and position caused her little inconvenience, was irregular in form, and consisted of three or four lobulated tumours.

The woman made a rapid recovery after the operation, the wound healing readily without a bad symptom.

WESTMORELAND LOCK HOSPITAL.

ON Tuesday, the 7th of September, we had the advantage of seeing a female patient in the above hospital, on whom Mr. Mc Dowell had on the previous day performed the operation of laryngo-tracheotomy, to relieve the asphyxia dependent on acute idiopathic laryngitis. The patient, who had ceased to respire at the moment of the operation, was, when we saw her, progressing most favourably, and still continues to do so.

We will publish a detailed account of the case in a later number.

EXTERN MATERNITIES AND LYING-IN HOSPITALS.

A REPLY TO CRITICISMS ON A COMMUNICATION TO THE DUBLIN OBSTETRICAL SOCIETY.

By EVORY KENNEDY, M.D., F.K.Q.C.P.

(Continued from page 257.)

On the other subject, the mortality in proportion to the numbers, Dr. Beatty offers a very simple, but to me inconclusive denial, that "it is notoriously not the case." The Society might not, perhaps, be quite satisfied were I to answer Dr. Beatty in his own language, and simply assert that it notoriously is the case, as I have proved by the statistics of the lying-in hospital, and it notoriously has been the case since its foundation. On no occasion in which the hospital was crowded was not the crowding succeeded by metria, and the metria was not banished until the numbers were lessened, and separation, as insisted upon by Dr. Beatty, carried out. I explained this upon a principle, which must attract more attention than it has hitherto done, in the investigation of zymotic diseases; namely, the principle of cumulation. The duration and development of zymotic disease generally will acquire much elucidation by

the study of the habits of metria, and the application of the principle of cumulation in our great lying-in hospital. Dr. Beatty asks, "Why have there been long intervals of years, sometimes when the largest number of women have been confined during which no metria has occurred?" In the first place, I deny the long intervals of years. The tables of the Dublin Lying-in Hospital prove directly the reverse. Let us test this by Dr. Collins's death-rate, calculated from the one solitary instance of four years of freedom from the disease, which stood at 1 in 184. Now let us see how many years of the 111 that the hospital has been open for, have ranged above, and how many below this death-rate. Out of the 111 years, 104 have ranged above it; therefore, we might insist upon 104 years out of the 111 having exhibited metria; but, as this would include some years that approximated too closely to the limit, we shall strike off thirty from Collins's average mortality, and calculate that metria was present in the hospital every year that the mortality arose to within thirty of his average death-rate for his four successful years—a calculation that cannot be objected to. Now what is the result on this calculation? that out of 111 years of the hospital's existence it has only been free from metria for eighteen years, and has been haunted by it ninety-three years, or more than five-sixths of the time that has elapsed since its opening. Again, let us test the assertion of the long intervals of years without metria, when the largest number of women were, as Dr. Beatty says, confined; an assertion in which he by no means stands alone, as Dr. M'Clintock, Dr. Atthill, and several other learned doctors, too numerous to mention, make the same assertion. If we abstract Dr. Collins's exceptional period of four years' freedom from metria, which provisionally affords us a sufficient duration of healthiness to base sound sanitary calculations upon, in analysing its history, for no period, throughout the existence of the institution but one has it been three years free from metria. That was from 1781 to 1782 inclusive. Only twice has it had two years' freedom, namely, 1807 and 1808; and, in the fourteen years of the eighteen for which it was free it was only for one year at a time that the immunity existed. No long time for the cumulative process to develop its poisoning principle.

So much for the assertion of the long intervals of years in which no metria has occurred, and for Dr. M'Clintock's joke of the long period of gestation.

Let us now turn to the appendix, cast our eye over the tables, and test the effect of crowding by showing the relation in which increased numbers have stood to mortality, from the foundation of the hospital to the present day. I regret delaying you with this, but it is imperative.

Let my readers also examine the table of curves, which indicates this relation at a glance, for which I am indebted to my friend Dr. Wrigley Grimshaw, our authority upon this admirable plan of illustration. If this, with the detailed enumeration set forth in the appendix, fails to satisfy the most sceptical of my opponents of the relation between crowding and mortality, and of the Dublin Lying-in Hospital having been for 97 out of 111 years of its establishment the habitat of metria, as well as of its being now a persistent endemic in that institution, it only remains to decide whether the failure results from want of proof, or from wilful blindness and their being incorrigible.

I have, in the appendix, gone into the details of each year of the last or altered period of the hospital, since the disease became truly endemic, to show that even in this period a further increase was added on each occasion to its permanent high rate of mortality by increasing the number of women delivered under the same roof, in the same manner exactly as was the case when the disease assumed more of the epidemic character in its attacks; I mean in those periods of the history of the institution when occasional healthy years cropped up, with alternating outbreaks of metria more or less severe.

This brings our annual analysis of the hospital to its conclusion, and confirms with a confirmation, "strong as holy writ," our two positions, the fourth and fifth, that have been so much attacked, and which we submit are now placed beyond the possibility of cavil.

Dr. Stokes states, in his observations upon my paper, that there are two elements in the production of a disease from poison, such as metria, receptivity, and poison. Now, with great deference to my learned friend, if he will read my propositions correctly, he will find there are three. The first is the being a parturient female. This may be defined as the condition precedent. The second is the existence of circumstances favourable to its imbibition; and the last is the existence of the poison.

Dr. Stokes overlooked the second altogether, and disregarded his logic by the substitution of a middle term different from mine when he put such language into my mouth as—"That a natural process, such as parturition, should be of necessity coupled with a tendency to develop a fatal poison."

My language, my ideas communicated, and my logic are exactly the reverse of this. My proposition stating—"That this poison may be generated by any parturient female, and where the circumstances are favourable to its imbibition it may be absorbed into the system of the generator, or that of any other parturient female exposed to its influence."

From this it is patent that my intention was not to convey such an extravagant or erroneous idea, as that a natural process, "such as parturition, should be of necessity coupled with a tendency to develop a specific and fatal poison," which, no doubt, would have been, as Dr. Stokes characterizes this creature of his own fancy, "a startling proposition." But to convey what is conveyed as plainly as language can convey any idea, *ipsissimis verbis*—"That this poison is not of necessity generated by every, but may be generated by any parturient female where the circumstances are favourable to its imbibition, and absorbed into the system of the generator, or that of any other parturient female exposed to its influence."

I am not, then, placed in the position that Dr. Stokes had designed to land me in, of proving that the "natural process that secured the existence of man upon the earth is necessarily coupled with a tendency to develop a specific and fatal poison."

Dr. Stokes next lays down a very sound rule in philosophizing that we should, where there are two methods of explaining a certain phenomenon, accept the most probable. Now, let us test his own views upon this principle. He says, I myself have not the slightest doubt that "contagion is less the cause of the spreading of puerperal fever in hospitals than epidemic influences. What these epidemic influences are no man can say," &c. Again, one of the most remarkable instances with which I am acquainted in favour of the epidemic influences in producing puerperal fever as distinguished from contagion in lying-in hospitals "is the great fact that women are simultaneously affected by puerperal fever in the hospitals where they have been entirely separated, and where even the attendants have not been the same."

Now, let us apply Dr. Stokes' test of probability to this position. Is it possible, let me ask him, to find the state of things he describes in the lying-in hospital without a case of puerperal fever in the district outside of it, a state confirmed by my own experience as well as that of most other masters of the hospital; and yet to persevere in ascribing this disease to epidemic, not endemic, and contagious influences as the more probable cause?

Is it more probable that a disease that has haunted the Lying-in Hospital of Dublin, as I have proved by its statistics for 97 out of the 111 years it has been opened, should be more due to endemic and contagious causes, or to epidemic causes, when the districts surrounding the hospital, taking all the years it has prevailed epidemically in Dublin would not amount

to a tithe of those in which the hospital has been scourged with it? Is it more probable that a disease existing, and repeatedly existing *in* the hospital and *not* appearing *outside* should be due to causes operating within the hospital, and not to causes operating without?

But Dr. Stokes begs the question in his proposition. He says the women are simultaneously affected. This is not my experience of even what we term an outburst of puerperal fever. On the contrary, patients are consecutively attacked. Unlike the occurrence of influenza—the best specimen of epidemic disease—which often spreads to hundreds of cases in the course of one day or night, and depends, as we often observe, upon sudden atmospheric changes, metria begins usually by a dropping case, then in a few days another, then the plot thickens as the atmosphere becomes pervaded with the poison, and fresh victims are in the state of receptivity. Again, the influenza disappears or dies out with the alteration of the physical or atmospheric causes that produced it. Not so metria in hospitals, as we have had too painful evidence in what has preceded. Is it, therefore, *more probable* that with this state of consecutive development of the disease, it should not be more ascribable to endemic and contagious than to epidemic causes?

But Dr. Stokes again begs the question. He says, "Where they have been entirely separated in hospitals the disease has spread." But have they been entirely separated? This is the very point I have been devoting all my energies to accomplish." This is the very question at issue—Whether they are to be entirely separated?—and this is the very view of the question that I regret my friend Dr. Stokes has thrown in the weight of his great influence to prevent. If he will join me in this one point—namely, the entirely separating the patients, I shall hail him as an advocate of the cause I have so much at heart. But what is the fact? It is impossible, and I know it by painful experience, "to entirely separate" a number of people living under the same roof, and who must necessarily breathe the same atmosphere. I have tried it, and I might just as well, to use a homely adage, have attempted to stop the tide with a pitchfork.

But Dr. Stokes alludes to the selection made in patients being attacked or contaminated in different parts of the same building, and looks upon this as incompatible with contagion or endemic influence. Why, it is the very essence of its nature that contagion, that the pestilence that walketh in darkness, should charge an inclosed atmosphere and hang about or haunt it, moving from room to room with the currents that invade the building, resting for a time in one from stagnation, and then moving away to another. And here Dr. Stokes's receptivity comes into play in explaining the selection of its insidious attack. The circumstances are favourable to its imbibition, and the victim is struck. What can be more probable than all this? Contrast with it the probability of an epidemic metria, which *does not exist outside*, permeating the hospital, selecting one victim after another, within its walls, say even in distant chambers, and never going beyond the hospital, the disease dying out after a time on the law which regulates these strange variations, returning in the same manner; and this often occurring, again and again, as I have known it to be the case, before selecting some cases for attack in the district. These cases frequently traced, as I have done, to the patients of the same practitioner, who was at the moment attending the infected hospital, and thus dying out in the district only to crop up in the hospital again at a short interval. And then let us repeat the question, to which cause, epidemic or contagious and endemic influences, are we to refer hospital metria as most probable? Surely there can be no hesitation, to use Dr. Stokes's own language, that of these two methods of explaining the phenomenon, metria, we should accept that which is most probable, and which, with much deference to him, I submit I

have thus, on his own test, established to depend upon endemic and contagious, not epidemic, influences.

But, Sir, before leaving the subject of epidemic, the derivation of the word implies that it is a generally prevalent and atmospheric pervading influence, operating physically upon man, animals, and plants. It may be by alteration in the physical properties of the atmosphere simply, as sudden changes from heat to cold, from drought to moisture, or the reverse; or from changes either thus indirectly or directly produced in its electricity. Under this class of cases may be mentioned as epidemic, influenza, rheumatism, facial paralysis, dropsies, produced by checking the insensible perspiration, &c. It may be from the loading of the atmosphere with a noxious or poisonous exhalation of a vegetable or earthy nature, such as ague or those fevers of tropical climates, pervading certain localities, and from which our soldiers suffer on too near approach to the coasts. Or it may be from the atmosphere being loaded by animal poisons or exhalations, such as we observe from defective sewage in cities, when typhoid fever, diphtheria, and typhus prevail. Or, lastly, it may be a disease requiring contact or approximation of the diseased with the person to be affected, and ascribable to the direct communication of a poison from the one to the other. Whooping-cough, the exanthemata, mumps, furnish us with such examples.

But why do we dwell upon these truisms? Because there is a great scientific distinction and a great practical lesson to be learned from their recapitulation and study. The first group described should be classed as quite distinct from the others, as all pervading, and not necessarily depending for its production upon the contamination of a poison. It is non-preventable, and in its attacks all are susceptible to its influence. Nevertheless, some of the diseases of this class, as influenza, are capable of transmission subsequently by a poisonous influence generated in the person attacked.

(To be continued.)

Literature.

SPECIAL REPORT

ON

STUDENTS' TEXT BOOKS.

(Prepared expressly for the MEDICAL PRESS AND CIRCULAR,
by Professors in Schools of Medicine.)

No. II.

In resuming our Report on Students' Text Books, we are brought at once face to face with the intimate association between Anatomy and Physiology. The two may almost be looked upon as one, and yet for the purposes of the medical student they are very properly divided, and even subdivided.

If we regard only the scientific aspect we may consider physiology as the crown of the whole, and yet if we spoke for others than medical students, we should recognize how little anatomy they learned for the sake of the physiology. The devotion to anatomy, the practical acquaintance with it which medical men possess, will always give them, as a class, an advantage over all other physiological inquirers. It is this which places them in the position of artists, where non-medical physiologists can only rank as amateurs. Even the very brief but clear and excellent "lessons" of Professor Huxley, which we noticed last week, recognize the importance of anatomy. We cannot do better than

quote that great author's words to enforce this truth. In his preface to the second edition he writes, "It will be well for those who attempt to study elementary physiology, to bear in mind the important truth, that the knowledge of science which is attainable by mere reading, though infinitely better than ignorance, is knowledge of a very different kind from that which arises from direct contact with fact, and that the worth of the pursuit of science as an intellectual discipline is almost lost by those who seek it only in books."

This lesson from a great master needs no further confirmation from us, nor need we proceed to follow him in encouraging others by showing how the butcher's shop may be called upon to provide the organs of inferior animals for practical anatomical study, though we may remark that the same resource may advantageously supplement the dissection of the human frame which the medical student is called upon to perform.

As anatomy is the basis of physiology, so is osteology the foundation of anatomy. Without a knowledge of the bony framework it is impossible to acquire a full appreciation of the whole body; and the study of the bones is still further to be inculcated, inasmuch as a knowledge of them is directly required in practical surgery.

A much more minute and accurate acquaintance with osteology is required of the medical student than is necessary for physiological studies, and than would be expected for degrees in arts or sciences where physiology is required. The first portion of the student's anatomical study is therefore devoted to this. Many teachers advise their pupils to give up the first half of their first winter to this division, and on no account to begin dissecting until after Christmas; and we think the advice is sound. There are some, indeed, who in apprentice days have made considerable advances in this, being possessed of a good skeleton, or a part of one, and studying it with a book. This can easily be done, and we certainly commend all who do it. Plates alone, beautiful as some are, will not suffice, and the skeleton must be studied bone by bone. It must be felt and handled and minutely examined for the purpose of the medical student.

Most of the anatomical manuals contain descriptions of the bones with engravings, and point out the main facts, to be remembered, every one of which should be sought out in the skeleton, the fingers thus aiding the memory in this, the driest part of anatomy. Other books are devoted solely to osteology. There is a small book of Mr. South's, "A Description of the Bones," which may be picked up at any old medical book shop for a few pence; this will be found very useful to young students and apprentices. The engravings are good and the descriptions concise. We have a very lively recollection of "South on the Bones," which was at one time our pocket companion, and by the aid of which, and an imperfect skeleton, we made much progress before commencing our hospital career. We owe the veteran surgeon whose severity at the college examinations we afterwards tested and found it nothing to fear, thanks for the help of his little book in long past days; and we hereby discharge our debt.

Mr. Luther Holden, of St. Bartholomew's Hospital, has brought out a magnificent work, entitled "Human Osteology." It comprises a clear description of all the bones, illustrated with a large number of lithographs, drawn by the author, delineating the attachments of the muscles and other points in a manner that has never been

excelled. The fourth edition of this artistic work will be ready next month, and no doubt Mr. Holden will have revised it with his usual care, so that we may possibly have another opportunity of speaking of it. Judging of the first edition, the only one we have personally used, we cannot too strongly impress upon students the great value of Mr. Holden's book, and we predict that the new edition will be eagerly purchased. The same author's excellent "Manual of Dissection" is naturally much used at St. Bartholomew's, just as Ellis's "Demonstrations" is a sort of recognized book at University College, Gray at St. George's Hospital, and Wilson's "Manual," and the "Dublin Dissector," at many other schools. Gray's "Anatomy" is one of the very best for home reading, only to be rivalled by the still larger work of Quain and Sharpey, which few students will like to begin upon. In the dissecting room, Ellis, we think, is tedious from its excessive minuteness; and students naturally rebel against too fine descriptions of cutaneous nerves. Only Holden can compete with the "Dublin Dissector," a book that has maintained its repute as the best dissecting room guide through five editions, and is now revised by the learned Professor of Anatomy in the University of Dublin (Mr. J. Harrison). Of Heath's "Manual," we are informed that an enlarged and revised edition will shortly be out, and we have not yet mentioned Ledwich's "Practical and Descriptive Anatomy," nor the beautiful account of the "Anatomy of the Arteries," by Professor J. Hatch Power, both of which deserve full notice; so that it will easily be observed that we may fairly postpone the completion of our remarks on anatomical text-books.

Freshmen will confine their first purchases to the osteological department, and can thus hear what we have to say on other books before purchasing them. They will, however, be asking for more on physiology. Of the larger works on this subject what shall they buy? What are their several distinctions? There is a choice. Marshall's, Kirkes's, Mapother's, Carpenter's large work, and his Manual, as well as some others, can be relied upon, and numerous books may be perused in addition. To these important text-books, then, we now turn.

Marshall's "Outlines of Physiology, Human and Comparative" (Longman's), is, as the title conveys, a very comprehensive work. It consists of two thick volumes, profusely illustrated by first-class wood-engravings, and was published at the end of 1867, so that it is brought down to a very recent date. Mr. Marshall treats physiology as dependent, to a large extent, on chemistry and physics, as well as anatomy. This we think quite right, and as he has not overdone this, but expects the student to know the elements of chemistry and physics, so far as to understand his descriptions, he has produced a text-book which may lay claim to completeness for the medical student, and will also admirably serve the purpose of intending graduates in arts and sciences, or of students of Nature generally. How important this is may be seen by looking at the description of any organ,—its structure, its physical and chemical properties, and the conditions, whether mechanical, physical, or chemical, through which, or in conjunction with which, its physiological functions are performed; all these are carefully described, besides which the distinctions between the functions in man and the animals in each case are fully illustrated. Here, then, is a work abounding in informa-

tion, arranged in due order, and only wanting careful study to enable any one to learn all that books can teach concerning physiology. It is encyclopædic in its mass of facts, but these are all classified, moulded into one homogeneous whole for the reader's benefit. It contains all the medical student needs, and is, moreover, just the book for all other persons who desire a comprehensive work on the great subject of which it treats. To justify our recommendation we will sketch briefly the plan of Professor Marshall's book.

The first volume opens with an introductory sketch of anatomy, giving a general plan of the body, and an account of the textures of which it is composed, the microscopic structure, physical properties, and chemical composition of these tissues included. Next follows general physiology, under which are sketched the vital properties of the tissues, and an account of the functions of the living animal. Pursuing the comprehensive plan laid down, Mr. Marshall now enters on the relations of man to other animals. This involves a sketch of the animal kingdom as a whole, and a comparison is then drawn between this and the vegetable and mineral kingdoms. It will thus be seen how broad a base Mr. Marshall proposes to build upon, and how extensive is the field of knowledge he brings under cultivation. More than 150 pages are occupied with this preliminary portion, and then we enter upon special physiology, in which the animal functions are successively described. Animal motion is the term applied to muscular contractility and ciliary movement. The various movements of animal bodies are treated of separately, in the following order:—Locomotive organs; mechanics of the body; forms of progression; locomotion on solids, in fluids, and in air; prehension and manipulation; expression and gesture; voice and speech. Under the last head we have the anatomy of the organ of voice, a sketch of the mode in which sound in general and the voice in particular is produced; the difference of voice in man and animals from speech, and so on. This carries us past the 270th page and introduces the next section, that on sensation generally, and the functions of the nervous system. Then follows a sketch of each of the senses, every organ being fully described. This brings us to the close of the first volume, which contains 607 pages.

It will be seen how much remains to be treated in the second volume, which, in some Manuals, is taken up at a much earlier stage. That part of this valuable work treats fully all the functions of so-called vegetative life. Digestion, absorption, the circulation and respiration, sanguification, nutrition, secretion, excretion, &c.—all these are fully and clearly described, and we have further embodied in the book what the student requires to know about animal heat, light, and electricity, and their relation to chemo-vital action.

There is a separate division on "Animal Statics and Dynamics," in which are discussed the specific gravity, stature, and weight of the body and its organs, the balance between the ingesta and egesta, the forms of force exerted on the body, and their relations to the food and air consumed and the chemical processes in action. The subject of reproduction in the animal kingdom is treated fully, the evolution of the chick in the egg being taken as the groundwork for the description of the embryo. The second volume is brought to a conclusion with a concise description of the growth, decay, and death of the body.

We should add that there is, what every Manual should possess, a copious index, which makes it a very valuable work of reference in any of the many subjects included in it.

We have been thus particular in telling the reader what he will find in Marshall's "Physiology," as we desire to encourage the careful study of such a comprehensive yet well-knit work. It will be seen that while the author has made physics, chemistry, and anatomy, the triple foundation on which he builds the science of physiology, he has so thoroughly finished his work, that we have, as it were, presented to us one harmonious whole. Such a book as this cannot fail to be of immense value to medical students, and those who possess and use it will make their physiological studies pleasant, while they need have no misgivings about examinations to come. For students in other faculties, teachers in schools, intending graduates in arts and sciences, and all who enter upon the study of Nature in earnest, we know of no book to be preferred to Mr. Marshall's. Still, as we have already said, we advise all to precede this by a briefer and more elementary work, and we would also repeat our recommendation to read other works. There are a number of books that may advantageously be read by way of varying the study, by those who make this their text-book. Moreover, for medical students, there are other Manuals which may claim to rival this, whether for the popularity they have obtained, the position of their authors as physiologists, their general use in certain schools of medicine, or their exact adaptation to the wants of the medical student. To them, therefore, we now turn, with a view of pointing out their chief features.

(To be continued.)

HYPERTROPHY OF ONE HALF THE BODY.

Prof. Samuel Logan (*New Orleans Journal of Medicine*) reports the case of a girl, with the following history: age four years; well grown for age; parents, as well as self, are natives of Louisiana; has seven brothers and sisters, all of whom are healthy. The parents are both healthy in every respect; the mother has borne twins three times, the child who is the subject of these notes not being, however, one of the twins. The family history as regards health is excellent, except that one of the mother's brothers has two out of six children deaf and dumb, but the mother of these children is delicate and in no way related by blood to the family of this child. About ten days after birth, the right half of the person of the infant was found to be larger than the other, and since that time the disproportion has seemed steadily to increase. She is now a strong, hearty child; but the disproportion is marked in every particular, more so, however, when the opposite extremities are compared. One leg is about an inch larger than the other, causing a peculiar gait, and the foot requires a shoe at least one and a half or two sizes larger, and the two arms and hands show a corresponding disproportion. The difference is, of course, not so marked, but can be readily seen, in the head, the eyes, the nose, the tongue, and the trunk all the way down. The only very serious attack of sickness from which the child has ever suffered, she experienced in September, 1867, when she was very ill with yellow fever, having had black hemorrhage by the bowels. I am informed that her recovery from this attack was tedious, and that, about ten days after convalescence was considered established, a portion of the alveolar process of the lower left maxillary bone, containing one incisor and a canine tooth, the latter embryonic, sloughed off. Since this she has been restored to her usual good health.

VACCINO-PHOBIA.

No. II.

THE spread of vaccino-phobia deserves some attention from medical men, for the public mind is easily alarmed, and the fanatics who have set themselves up to oppose the prevention of small-pox are by no means scrupulous as to the means they employ. Some of them actually set up a periodical, in which anti-vaccinators may have their silly effusions printed; and it would seem that there are people so far gone as to subscribe for the gratuitous distribution of this compilation. We would by no means impugn these people's honesty of purpose; but we do feel saddened at the utter ignorance they display, the sublime defiance of logic they evince, and with all their pretence of doubting the inexplicable credulity of which they are the victims.

They rave over the terrible eruption that here and there they declare a child has had after vaccination, oblivious of the fact that the same eruption might have come out if the child had not been vaccinated—nay, that such eruptions do occur every day in unvaccinated infants. It is always so; *post hoc ergo propter hoc* is the one argument that the ignorant employ, without seeing its fallacy; the simple means of exciting the fears of the anxious, the time-honoured weapon of quackery and superstition. How should it be met? It is easy enough for one case produced by the vaccino-phobiacs in support of their statements, to find a dozen on the opposite side, or to find still more cogent cries to prove a different cause. So far as logic is concerned, the man who disbelieved in the efficacy of vaccination because his child, after the operation, fell out of window, was as reasonable as many of these noisy agitators against a beneficial practice. So it may just as reasonably be maintained that the alleged evils imputed to vaccination are really due to other causes—to diet, to cold, to change of weather, to eating fruit or plum-pudding, or drinking milk or beer. It would be well for every professional man who may be asked about the dangers of vaccination to explain the fallacy of the one argument relied upon by the vaccino-phobiacs.

We think, further, that too much has been admitted by some in their eagerness not to overstrain the matter. The talk about the conveyance of various dire diseases is utterly unjustifiable. The cases that have been brought forward, if carefully examined, prove nothing of the kind; and all accurate observation goes to show that the alleged propagation of disease does not occur. Why, MM. Heim, Taupin, and Cullerier tried a number of experiments, and were unable to propagate disease with vaccine lymph, though they tried their best to do so. We need not repeat such experiments—they are scarcely defensible according to our notions—but as they have been made, we may take them into account. If, when *unhealthy* children were selected for the express purpose of trying if disease could thus be propagated the experiment failed, surely when lymph is taken from only *healthy* children, and every precaution is used to prevent any evil, we cannot credit that vaccination really is a common means of inoculating diseases.

A great deal has been made of the candour of many thoughtful men, who are too ready to admit doubts where they are not certain. The recent letter of Dr. Seaton was, to our minds, far too weak. It admitted that of which there is no proof, and yet asserted that which would be excessively difficult to prove, and was, on the whole, a very unsatisfactory performance. It would surely have been easier to say something far more to the point. Even if serious evils did occasionally result from the operation, we should say that vaccination was worth the cost. How much more, when doubtful temporary inconveniences are alone in question?

The public should be informed that Jenner's discovery has almost banished one of the most loathsome pestilences. We know nothing of small-pox now in comparison to what our forefathers knew of it. In each of the three years, 1838-40, before there was any provision for gratuitous vaccination, small-pox slew on the average 11,944 persons in England and Wales. In the nine following years, during which gratuitous vaccination was provided, the annual average was 5,221. In the next ten years, when it became to some degree obligatory, the average was 3,351, and with compulsion it is sure to rapidly decrease. This last number represents 171 deaths per million of the population, as against 304 and 770 in the preceding periods named. Dr. Lettsom and Sir G. Blanc estimated that the number was at least 3,000 per million, as the annual average of thirty years prior to the introduction of vaccination. Can figures speak plainer?

In Ireland, as Dr. Cameron has last week exclusively shown, small-pox has been almost stamped out by the careful and systematic manner in which vaccination has been carried out. He tells us that “during the ten years ended in 1841, no fewer than 58,006 persons perished from small-pox in Ireland, and three times that number were disfigured for life by the ravages of the disease. During the decade ended in 1851, the deaths from small-pox numbered 38,275, and in the following decade the deaths from this disease amounted to 12,727. In the year 1866, 186 deaths occurred, and in 1867 only 20 persons lost their lives from small-pox. Last year 19 persons died from small-pox.”

Dr. Cameron remarks that “in studying the statistics of small-pox in Ireland, it is impossible not to be struck with the fact, that just in proportion to the efforts made

by the Poor-law medical officers to carry out vaccination, so have the cases of small-pox diminished."

We leave these figures to speak for themselves. The Profession has only sought to banish small-pox. The vaccino-phobiacs in their ignorance would set up some trivial inconveniences, which they imagine are produced by vaccination, as enough to counterbalance the benefit of delivering us from the greatest scourge of modern times. When they would bring back small-pox as it was in preference to these alleged petty complaints, they can only be excused because they know not what they say.

THE LUNACY REPORT.

THE first heading of this important Blue Book* is statistics. We find that there are at present in England and Wales 6,224 private and 46,953 pauper lunatics, making a grand total of 53,177 of our number. This shows a slight increase of 2,177 insane persons over the total of 1867. The total weekly cost per head of these, it appears, averaged in county asylums 9s. 2½d. a head. In the Report preceding the one before us, the Commissioners brought under special notice the pressing want of additional asylum accommodation for the pauper lunatics of the County of Middlesex. The visiting Commissioners, in 1869, found that at Colney Hatch, in the space of little more than twelve months since their previous visit, no fewer than 562 distinct and separate persons, all of them pauper lunatics belonging to parishes in the County of Middlesex, had been refused admission into that asylum, the entire number of vacant beds at the time of their visit being five; so that, supposing the number first stated to represent only those for whom admission had already been sought at Colney Hatch, this would yet leave nearly 600 Middlesex patients, in the course of less than one year, turned from the doors of one of its asylums alone.

The excuse for this inaction seems to have been, that the magistrates felt themselves under the necessity of waiting "until it could be ascertained to what extent the asylum clauses of the Metropolitan Poor Act might prove to be available for supply of the desired accommodation." The Poor-law Board, however, it appears, observed that not only they held that the Legislature had intended, by these asylums, to provide for such harmless and imbecile cases only as could by law be retained in workhouses, and that they had never contemplated the removal and reception into them of persons who could not properly be treated in workhouses. The Commissioners on this seem to have explained this matter clearly to the magistrates; but they are obliged, in their Report, to declare themselves to be again disappointed by the inaction of these gentlemen. The Commissioners, therefore, it appears, were obliged to call in the assistance of the Secretary of State, to compel, by the authority vested in him by the Lunatic Asylums Act, 1853, the magistrates of Middlesex to erect, without delay, a third asylum for at least 1,000 patients. The consequence of the crowded condition of Hanwell and Colney Hatch Asylums has been, that several most dangerous cases have been found to be living in several of the workhouses. For example, in the workhouse of St. George's, Mount street, Grosvenor Square, there was found a woman in acute mania, restrained by a strait jacket in bed, and who threatened the life of one of the two pauper nurses in attendance upon her; and a woman was retained at Westminster for six weeks in a state of violent mania, strapped to her bedstead for several days and nights together. Again, the Commissioners visiting the workhouse of the Holborn Union, found two women, the urgency of removing whom had become so great that, during the week before, applications had been made, without effect, to no less than nine asylums, public and private, in London and

the provinces. "With wearisome frequency," say the Commissioners, "the application has come to us, 'we have now another lunatic inmate who ought at once to be removed, but the county asylums and all the metropolitan asylums are full.'" It seems, too, that it has now become a perfectly hopeless thing to expect admission for any pauper paralytic patient into any lunatic asylum in Middlesex.

The Commissioners complain that there is very great want at present of hospitals in which the insane of the middle class who, though poor, are not reduced to pauperism, may be received at small sums, varying from 5s. to 10s. and 15s. a week. So inadequate is the charitable aid afforded to this class at present, that the pauper asylum is the only resort for them; and daily increasing numbers are sent there as ordinary paupers, the parishes being partly, or in some instances wholly, reimbursed for their maintenance.

To such an extent is this practised in county asylums as to be frequently matter of formal complaint by the visitors, imposing, as it is argued, a burden upon the rate-payers which they are not legally called upon to bear. To the patients themselves, also, it is no less a hardship and an injustice; and painful cases are constantly coming under observation in which persons of education and social position—clergymen, barristers, medical men, and others who, from reduced circumstances, are unable to meet the lowest charge at which admission can be obtained into licensed houses—are, as a last resource, driven to associate with paupers. The weekly cost of patients in lunatic hospitals, it seems, varies from £1 1s. 9d. to 11s. 3d. In the case of the Bethel Hospital, the establishment charges are very low. The cost in the Lincoln Hospital of 17s. 7d., and in the Retreat at York, the Warneford Hospital, and that of St. Thomas's at Exeter, of little over £1 a week, represents, probably, with sufficient accuracy, the amount at which patients may be maintained in lunatic hospitals not receiving to any great extent those of a high or remunerative class, and yet obtain every care and accommodation. The Commissioners think it important to state, as a general rule established by much experience, that the erection of large and expensive buildings is neither desirable nor expedient. We are glad to see that these gentlemen agree with Sir J. Y. Simpson in their department.

In reporting upon St. Luke's Hospital, the Commissioners observe that the Resident Medical Officer, who, according to the Lunacy Act and the uniform practice in similar cases, ought to be the Superintendent, is not so in fact, but is substantially deprived of that paramount influence which it is most important should be vested in such an officer. St. Luke's is not the only hospital in London which might be complained of on the same score. On the 1st of January, 1868, there were 79 patients in St. Luke's paying at the rate of £1 3s. 4d. each per week; the charge to the paying patients now is £1 1s., but 38 are on the old list, and pay less than 10s.; 41 pay the guinea. But there has also, it seems, been much vacant space in the hospital for some time past. The wages of the attendants seem to be very low in St. Luke's, as evinced by the frequent changes in the staff. The disadvantages of the site and structure of St. Luke's Hospital are frequently alluded to by the Commissioners; the difficulty, too, of getting walks beyond the walls, and the gloomy nature of the rooms occupied by sick or bed-ridden patients.

The Commissioners observe that they think the Governors of Bethlehem Hospital ought to have sold their hospital some years ago to St. Thomas's Hospital. They fear that there is little chance of this hospital being now removed to the country. The whole of the criminal lunatics are now, it appears, removed to Broadmoor. The condition of the hospital and patients was found in 1867 to be quite satisfactory. During the autumn, about 44 of the patients were taken to Brighton and Ramsgate, where three houses were rented for them.

With regard to Earlswood Asylum, the Commissioners

* Twenty-third Report of the Commissioners in Lunacy, July 14, 1869. Pp. 403.

praise the conduct of the asylum very highly. Epidemics of typhus and scarlatina seem, as one might expect, to have occurred. We have always doubted the advisability of any kind of children's hospital, and this the more confirms us in our prejudice against them. The water supply at Earlswood has been bad in quality, and it is likely that some change in the source will be made. Dr. Down resigned his appointment in 1868. The York Retreat is favourably spoken of by the Commissioners; ample means are afforded for walking and driving out. There are now 139 patients in it, and a large amount of charitable assistance is dispensed by this hospital; as many as 61 patients in the hospital on January 1st paying under 10s. a week, and 11 others from 10s. to 15s.

With regard to the insane in the workhouses, the result of the yearly inspections has been unquestionably to produce a gradual and general improvement in the condition of the insane inmates; but there are still great deficiencies. The dietary is often, it seems, very meagre, and notably so in Lancashire. The Commissioners think that the insane require more food than healthy persons do. The practice of retaining in workhouses cases requiring asylum treatment is very general. Among the cases most frequently retained are those of melancholia, when the disease is frequently of recent origin and curable form, but where, because the patients are not troublesome, and are not deemed to be dangerous, they are allowed to drift into a chronic and incurable state, and their chances of recovery by early removal and appropriate treatment, only possible in an asylum, are entirely sacrificed. The most fertile source of the evil complained of, however, and an indirect cause of much chronic insanity, is neglect of the duty imposed upon relieving officers by the 67th section of the Lunatic Asylums' Act, which requires that they shall, within three days of every case of insanity coming to their knowledge, give notice to a Justice, in order that due consideration, as contemplated by the Act, should be given as to the propriety of the removal of the patient to an asylum.

The Commissioners state that their experience more and more convinces them that the cost of an inquisition remains still excessive, and that it would be a great advantage, in cases where a lunatic's property does not exceed £2,000, and its annual income is below £100, no formal inquisition were required. Not a few persons are deterred, they think, from applying for an inquisition by the expense. An instance is given of a female lunatic, who was sent to Hanwell as a pauper patient; in her passage through a London workhouse £86 was found upon her, and was taken by the Guardians. This the Guardians retained, because she could give no legal receipt; and the Commissioners were obliged to advise her father not to proceed against them under the Lunacy Act, as such a proceeding, if successful, would probably absorb a fourth of the property. They recommend that some intermediate and easily applied protection should be found, limited in character, and procurable, as well as terminable, without undue delay, difficulty, or expense, for the property of persons who have been placed under certificates of insanity in asylums. It would seem advisable, they say, that, as soon as insanity is actually established, some *ad interim* and official, however limited, protection of his property should be accorded upon terms easy of compliance by his friends.

The first complete return of private and pauper lunatics, it seems, was made in January, 1847. The numbers detained under private care at that date were—in licensed houses, hospitals, and county asylums, 3,574; and as single patients, 130; which numbers in 1869 have risen, under the former head, to 5,900, and under the latter, to 324. Of lunatics belonging to the pauper class, there were, in January, 1847, 9,652 in asylums, and 5,987 in workhouses—total, 15,639; whereas, in January, 1869, these numbers are, under the former head, 28,785, and in the latter not less than 11,000, or a total of nearly 40,000. The great increase began to be felt when the Commission, having then existed eight years, first came to its present offices in Whitehall. Since that date 20,000 persons, at least, have

been added to the number of lunatics who are placed under control and constant supervision by the Commissioners. Such is a brief comment on this sad picture of human infirmity, the Commission on Lunacy. Byron, who has lately been accused of all sorts of offences against the Decalogue, called the human species that "bitter draught." Alas! when we read over this record of our frailties and our miseries, we cannot fail to admit that there was some truth in his epithet. Poverty, madness, and consumption seem to dog the footsteps of civilization, and to be rather on the increase with us than the reverse. Let us hope that Science may ere long do a little more for us than it hitherto has done.

SCOTLAND.

THE LATE DR. CHRISTIE.

JOHN CHRISTIE, M.D., F.R.C.S. Edin., has been at Aberdeen since 1846, and enjoyed the confidence of his Profession. His skill in obstetrics brought him a large consulting practice in that department, though for the last two years his health had compelled him to do less and less. He died of heart disease, at the age of fifty-one. For some time he was Professor of the Institute of Medicine at King's College, Aberdeen, and he filled a number of other offices.

THE LATE DR. SIDEY.

JAMES SIDEY, M.D. Edin., of Elgin, has passed away, at the age of sixty-four. The *Courant* describes him as a man whom all "not only respected, but loved." He had been in the Army, where he had gained the good will of his commanders and the friendship of his companions in arms.

THE INFIRMARY.

DR. ANDREW WOOD and Mr. Syme have expressed an opinion that, if Watson's site be built upon, the old Infirmary might be utilized for the administrative departments.

At the Glasgow Dispensary, Dr. A. W. Smith succeeds Dr. McCall Anderson, who has been promoted to the Infirmary. Dr. Cameron is the new extra surgeon to the Dispensary.

THE death of A. D. Brandes, Esq., Surgeon, of Forres, Morayshire, at the age of seventy-eight, is announced.

THE election of Examiners to the University of Aberdeen excites some interest just now. There is a difference of opinion as to whether the present Examiners should be re-elected.

MR. SYME has written a letter in defence of large hospitals, which deserves, as all Mr. Syme's utterances do, the serious attention of all, and which must be carefully considered by those who have given in their adhesion to the "small hospital" view.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The calendar has just been published; it states that the income from all sources during the collegiate year amounted to 10,852. 14s., derived principally from fees for diplomas, viz., 8,506l. The disbursements during the same period amounted to 10,669l. 15s. 4d.

Notes on Current Topics.

The Cause of Heart Disease in the Army.

PROFESSOR MACLEAN reverts in the new Blue Book to the cause of heart diseases in the Army, and emphatically reasserts that a large proportion of cases arise from the soldier's dress. In a word, that the so-called "soldier's spot" is a pathological fact.

Since the Royal Victoria Hospital was opened in 1863 up to last March, 22,625 invalids have been admitted from abroad, the vast majority being from India. Of this number 1,635 were sent home unfit for duty from disease of the heart. Of the cardiac cases, 24 died at Netley, 1,322 were discharged the Service, 276 returned to duty, and 13 remained on the 10th of March, 1869. The greatest number of cases returned to duty proved to be functional derangements due to a general anæmic condition, the result of service in malarial localities, the abnormal sounds and irregularities disappearing under an improved state of the general health, brought about by change of climate, rest, good diet, and the use of the preparations of iron.

It should be explained that many cases of palpitation have been classed with diseases of the valves. In all subsequent returns under the new nomenclature they will be differently recorded.

Palpitation is often a greater disability for military service than even valvular disease. It often happens that soldiers have loud heart murmurs without being conscious of much or any inconvenience, except under severe exertion; but palpitation causes distress, and at once disables a soldier from the performance of his duty.

This condition is almost invariably attended with dilatation of the right side of the heart. It is observed chiefly in delicate lads, and is often established in an extreme degree after a few years', sometimes after a few months', service. Once fairly set up, Dr. Maclean doubts whether it is ever cured, for he has kept young men under observation for months, under the most favourable conditions as regards rest, diet, and medicine; but on causing them to resume their ordinary dress and accoutrements, or to walk about the corridors of the hospital, distressing palpitation immediately returned, making further exertion impossible.

Many cases of palpitation are sent to Netley from all parts of the world under the head of carditis. Under the new nomenclature return this extremely inaccurate heading will disappear.

Taking 151 cases of heart disease from the Netley clinical records, 82 were under 30 years of age, and 39 between 30 and 40, the two extremes being 16 and 40; only 6 had had acute rheumatism; 22 had a distinctly recorded history of syphilis, and in only one case was there evidence of a gouty diathesis.

In 72 the aortic valves were diseased, with more or less hypertrophy of the left ventricle, where the disease was aortic obstruction.

The mitral valve was affected in 54 cases; in 25 the cause of disability was palpitation, often with dilatation of the right side of the heart.

93 cases of aneurism of the aorta have been admitted into the hospital. Seven died and the remainder were discharged the Service.

Between the 1st of April, 1867, and the 1st of April,

1869, 36 cases of aneurism of the aorta were under treatment at Netley. 26 were from India, 8 from North America, 1 from the Cape of Good Hope, and 1 from New South Wales; 18 were under 30 years of age, and 18 between 30 and 40. The youngest was 16, the oldest 40 years of age. The former was a lad invalided from India for headache following sunstroke; he fell down one of the hatchways of the transport, and to this he attributed his chest symptoms. The Medical History Sheet showed a rheumatic history in 5, and a distinct syphilitic history in only 3 of the cases. In 25 the disease was in the thoracic, and in 11 in the abdominal aorta.

Having summarized the facts thus presented, we come now to the inferences to be drawn from them, and here we are desirous of laying before our readers the exact words of Professor Maclean. He says:—

"A very notable fact in the above figures is the early age of the patients affected both with heart disease and aneurism of the aorta, I doubt whether, out of the Army, so many cases of organic disease of the heart (not having a history of rheumatism), or of aneurism of the aorta, could be found at the above ages out of a proportionate sick population in any civil hospital in this country. I do not think there is now much difference of opinion among Army Medical Officers who have inquired carefully into the causation of this large amount of suffering and loss by invaliding. The evidence furnished from this hospital, and the careful inquiries of the Pack Committee, point unequivocally to dress and accoutrements as the active agents in this distressing amount of mischief. The Pack Committee have, I believe, solved both the mechanical and physiological problems submitted to their consideration. So long as it is thought necessary to make the soldier carry what he is now required to do, I believe it would be impossible to dispose of it to more advantage. As the new system of accoutring the soldier can only be introduced gradually into the Service, it will be some time before we can expect to see any marked diminution in the number of cases of heart disease. I have thought it advisable, therefore, to place the above facts and figures, collected in the largest invaliding hospital in the kingdom, on record for future comparison."

Professor Maclean then proceeds to do an act of justice to the memory of the late staff-surgeon, R. H. Hunter, formerly of the 2nd "Queen's" Royal Regiment. This officer was the first to direct attention to this cause of diseases of the heart and great vessels in the Army. In the 1st volume of the "Transactions of the Medical and Physical Society of Bombay," there is a paper by this gentleman, entitled "Cases of Cardiac Disease and Tubercular Phthisis occurring in the Queen's Royal Regiment." In this paper Dr. Hunter thus expressed his views:—

"Ever since I joined the 2nd, Queen's Royal Regiment in Colaba, in 1831, I have been struck with the frequency of cardiac and aortic disease. At first I thought it might be connected with the same morbid state of the blood which gave rise to purpura, so frequent at that station; but it afterwards prevailed to an equal extent in Poona, where no such cause could be assigned. Neither does it appear to be altogether connected with rheumatism, though certainly most frequently so; but whether or not rheumatism be the first link in this morbid chain, a more sufficient cause for hastening its progress, I am convinced, is the active duty a soldier undergoes whilst buttoned up in his accoutrements. These, by compressing the neck and chest, obstruct the circulation to such a degree as to excite the heart to inordinate action, and cause great hypertrophy in the strong and muscular, or to dilatation in the weak and sickly. Again, in the former the natural resiliency of the aorta, being overcome by the inordinate force of the circulation, that vessel yields, dilates, and finally gives way, giving rise to aneurism.

"It seems extraordinary that now the effects of tight lacing on females are so well known, a soldier, intended for the most active and long-continued exertion, should be placed in a similar predicament when that very exertion is required. Is it possible he could be placed under more unfavourable circumstances?"

The Late Dr. Roget, F.R.S.

P. M. ROGET, whose M.D. Edin. diploma was obtained in 1798, died on the 13th inst. at Malvern. He became L.R.C.P. Lond. in 1808, Secretary of Medico-Chirurgical Society in 1811, and reached the presidency of that society in 1829. In 1814 he obtained the F.R.S. He was at one time physician to the Spanish Embassy. His Bridgewater "Treatise on Physiology," and his "Thesaurus of English Words and Phrases" are both well known to the public.

Scarlet Fever.

THE prevalence of this disease lends a somewhat painful interest to all that may just now be written about it. In reply to an appeal in the *Malvern News* for a "simple remedy, generally available and easily carried out, for preventing the spread" of scarlet fever, Mr. Frederic Smith has issued a very useful pamphlet, in which the duties of parents, nurses, schoolmasters, and local authorities are precisely laid down. We need not go particularly into the recommendations offered by Mr. Smith, which are such as will meet with the approval of all qualified to judge. We should, however, note that he supports the views of Dr. Wm. Budd on the value of inunction both as a remedial and preventive agent. The only objection we have ever heard against the inunction is, that it is a "nasty plan," and in private practice almost impossible to persuade people to try it. We quite agree with Mr. Smith that too many are suffered to return to the family too early, and that twenty-five days is certainly the minimum time during which the patient must be isolated. Even then he ought only to come after all the clothes have been completely disinfected. Mr. Smith proposes a "Scarlet Fever Conference, composed of the head masters of our public schools, assisted by such eminent men in the Medical Profession as they might deem it expedient to associate with themselves."

This Conference, like the Cholera Conference, would investigate everything relating to the origin and spread of disease, and agree upon a code of rules by which to hold it in check. There can be no doubt that much might be done by such union to prevent some of the ravages of this pestilence, and to spread a knowledge of the danger of propagating it. Those who have been able, as we have, to trace the outbreak of epidemics to single acts of carelessness or rashness, know well that upon those who have charge of schools devolves a terrible responsibility. We should, however, be rather disposed to place our confidence in a conference of medical men having the care of schools. Each would then explain to all the masters the details of what is needful. At the same time, the vigilance needed is so great that it is impossible to keep out scarlet fever unless all interested will join in the attempt.

The conference of masters could do no harm, and might do much good by taking measures to point out to parents and guardians the excessive danger, and consequently the wickedness, of sending to school children who have only just had the disease, who have not been long enough secluded, or whose clothes have not been thoroughly disinfected. We have known such a case spread the fever through a school. Means should be taken to let parents know this danger, and then, if they risk it, the law should hold them responsible.

The Scandal at St. Bartholomew's Hospital.

THE students at St. Bartholomew's Hospital are not disposed tamely to submit to the high-handed wrong perpetrated in the dismissal of Dr. Mayo, and old St. Bartholomew's men sympathize. The squabble now brought to a crisis has been long enough on hand, and it is felt that, without some unmistakable expression of opinion, tyranny will for the future be triumphant, and the Profession set at naught. We have heard some remarks that lead us to believe that some of those who have approved the act we condemn were induced to do so partly from the tone of the published appeal of Dr. Mayo to the Governors; but such persons ought not to forget that when a conscientious man is labouring hard to do his duty in an office for which he receives no pay, months of impertinent interference with his work, or contemptuous indifference to his complaints, naturally goad him into energetic and pointed language. See what these people have done. They dare not have the usual Introductory Lecture on the opening of the Session; and so this old School, alone in the metropolis, is to be opened without the usual greetings.

The students and former pupils feel that such ought not to be, and we hear that they will assemble formally and hold a meeting, in which the mismanagement and oppression complained of can be fully discussed. Of course they will not be permitted to hold such a meeting in any building belonging to the Governors; hence the necessity for the place of assembly being an outside one. We wish the meeting success, and trust all St. Bartholomew's men who can will go and hear the statements, and form their own opinions. We hope, too, the honorary staff will be represented there. They ought to keep silence no longer. Either a younger professional brother—no no crime but too conscientious a desire to do his duty to the patients entrusted to him—has been insulted by the lay Governors, and in him the whole Profession; or some strange facts have yet to be disclosed. The great physicians and surgeons of the hospital should know the truth, and surely they will be true to their Profession. If they suffer a knot of tradesmen and placemen to set at naught the higher feelings of professional honour without remonstrance or sign of protest, it augurs ill for all who come after them. Let it be known to all that the medical men are not paid servants; that the charity could not be carried on without them; and that professional services freely given to the poor are not only shamefully abused, but that the givers are liable to insult. What will the public then say? If we tamely submit, they will say it "serves us right."

There is much involved in the great issue to be fought out, and we most sincerely hope that at the meeting the mode of carrying on the contest may be discussed in all its bearings with the utmost calmness. Nothing would be worse, nothing would do more harm, than violence of language or an approach to unseemly conduct. Let those gentlemen who take up the cause of their Profession and of hospital reform remember how ready their enemies will be to exaggerate the least disturbance, and endeavour to brand their proceedings as ungentlemanly. Much may depend on this meeting. It may possibly lead to those reforms in hospital management for which the few have so long been working, and the many so long sighing. If all who see the evils that exist, who witness the farces daily enacted under the pretence of charity, who have found

their desire to do good paralysed by the ogres that batten on the Profession; if these would all join the little band of reformers who still cry in the wilderness, there might be accomplished such a change in hospital administration, and in the social relations of the Profession, as would prevent for many a long year the recurrence of that state of things which is a disgrace to a civilized nation, and a mockery of the holy name of charity. Bartholomew's men to the front! The army of reformers has work to do, and will go on recruiting till all abuses are swept away.

The London Hospital.

THE contest for the vacant Assistant-Surgeoncies may be looked upon as over, as the candidates have agreed to abide by the selection of the Committee. The Committee, after consultation with the Staff, recommended Mr. Macarthy and Mr. Reeves. The former is a pupil of the hospital, whose diligence has placed him in such a position that he would have almost certainly been elected under any plan. The latter is not a London Hospital man, but a Demonstrator at the Middlesex. The London Hospital men passed over would, no doubt, have been preferred, but that they were considered rather young for such a post. They can afford to wait. We hope the plan of referring claims to the Committee and Staff may be considered a precedent. If voluntarily adopted by candidates, it would soon be seen if it worked well.

Charing-Cross Hospital.

BESIDES the vacancy we noticed last week at this hospital, there are two Lectureships in the School to be filled up, those on Botany and Midwifery. No doubt there will be found gentlemen ready to accept these offices, and perhaps some one may condescend to attempt the organization of the Skin Department; but candidates should at least be aware beforehand of the restrictions to which they will have to submit. It would be a healthy sign if the Governors should be unable to fill the appointment. Men who work hard for charities should, at least, not lose all their liberty; but the system of gratuitous medical labour has made slaves of the Profession.

Dissecting Room Fees in Trinity College, Dublin.

NOTIFICATION has been issued that students entering for demonstrations and dissections in Trinity College are required to pay seven guineas before the 1st of December, and for dissections only four guineas, and for demonstrations only three guineas. Students of more than three years' standing in the dissecting room are privileged to use the dissecting room on payment of the sum of one guinea on entrance.

The Development of the Cerebellum in the Insane.

DR. MEYNART has recently reported at one of the last sittings of the Psychological Society of Vienna, that the brain of insane persons presents a remarkable development of the cerebellum, and that, on the other hand, its excess is much more considerable in women than in men, other circumstances being equal.

Snake Poisons.

M. DUMERIL has presented to the Paris Academy of Sciences a work on snake poisons. He quotes Dr. Brainard, of Chicago, to show that death from the bites of venomous serpents is less rare than may be believed. Thus, Dr. Brainard has collected 49 cases of death. In 10 of them death supervened twenty-four hours after the bite; in 22 the fatal result followed between the second and sixth days; and in 12, between the seventh and twenty-first days. The poison acts quite as vigorously on adults as on boys or children. Dr. Brainard has collected 15 cases of death in children of fifteen years of age; 13 in boys from fifteen to twenty; and 18 in men from thirty to sixty.

As an antidote to serpent poison, iodine and iodide of potassium have been indicated.

Transmission of Disease by Vaccination.

THE prolonged debate of the Imperial Academy of Medicine of Paris on this important subject is at last approaching its conclusion, with the result, it would appear, of almost completely disproving the allegation that disease is frequently propagated by vaccination. The *Union Médicale*, in its issue of the 9th inst., says that M. Depaul, the exponent of this theory, "finds himself at this moment completely isolated in his doctrines." If our readers have followed with the attention which they merit these debates, they will have learned—

1. That the degeneration of Jennerian vaccine matter is anything but proved.
2. That not a single authentic example of vaccinal syphilis, properly so called, has been shown to exist.
3. That the very rare cases of syphilis inoculated by vaccination are explained by conditions which exonerate completely the vaccine of any impurity.
4. That a great number of cases of supposed syphilis supervening on vaccination leave the most reasonable doubt as to their genuineness.
5. That other modes of vaccination may be encouraged, although they present no real and sensible advantage over vaccination from arm to arm.

Compulsory Vaccination in Bombay.

THE Governor-General has issued an order in Council in reply to the reports for 1868 on the Indian vaccination system. His Excellency congratulates the Service that the recent arrangements by which the department has been put on a better footing in respect to pay, are producing such good results.

In the year under report there were 280 vaccinators employed throughout the Presidency, and the total number of vaccinations in civil life amounted to 426,253, giving an increase of 34,838 over the number shown in the preceding year's report. Of these operations 93.5 per cent. were successful. The total cost was Rs. 111,524, which gives annas 4 and pies 2 for each vaccination.

The suggestions for having recourse to legislation for the suppression of inoculation, and for making vaccination compulsory within the limits of the town and island of Bombay, have been and are engaging the attention of Government, and we earnestly trust that the Indian Government, having at hand the amplest opportunity of

determining the beneficial results of compulsory vaccination will not permit itself to be deterred by the ignorant and foolish craze to which certain home newspapers have lent themselves, from providing for India a protection which is there even more essential than elsewhere.

The Collapse of the European Life Office.

SCARCELY has the public got over the shock of the fall of the Albert, upon which we have already commented, when another failure, probably still more disastrous, comes before the Courts.

The European had absorbed thirty-three other offices, and its manager was hailed as "the great amalgamator." Now, with prospective liabilities of some ten millions, there is a talk of £6 odd per cent. as the possible assets to be realised with a favourable liquidation! Policy holders have lost their money, annuitants find their income gone, and widows and orphans despair.

No wonder there is a crisis in the insurance world, and a prevailing opinion that several other offices must follow. And yet assurance business is not speculative; it ought always to be safe. Recklessness and robbery combined will, of course, compass the downfall of any such association, and in the crash that is impending we repeat our hope that every effort will be made to bring the wrongdoers within the meshes of the law. Compromise is to our minds absurd. We have seen such attempts, and in the end have noted their folly. The first loss is the least, and lives who need protection should at once transfer themselves to sound offices, and pay their premiums due to the provisional liquidator, by way of keeping up their claim upon all who may be liable. It is strange that no office of standing has, as yet, offered to take over the policy holders in the fallen concerns. If one could not, surely a combination of first-class offices might be able to take them over on favourable terms. Here are thousands of lives ready to insure,—to get them would be better than to squander money in trying to get those who are not so disposed. Why, it would pay to start a new office for the mere purpose of taking up these lives. To offer the usual discount allowed to agents would be an inducement, but we believe that a larger reduction could be afforded. Will no office—no two or three combined—try?

Convict Labour.

It would appear that after all that has been said, hard labour is not agreeable to convicts. Some feign insanity to escape it, others attempt suicide, and other forms of malingering exercise the faculties of the surgeons in charge of convict establishments. At Chatham, some produced ulcers and other appearances by putting splinters or threads under the skin, and covering the parts with lime. At Portland, worsted and ivy juice had been similarly employed; washing powder and ivy juice had been put in the eyes; black tongues were counterfeited by the simple device of ordinary blacking; more than once convicts have severed the tendo Achillis with pieces of glass. It would seem to be considered rather a sharp thing among their comrades to do the doctor, so that it has been thought well to isolate the prisoners. With this proof before us that the convicts hate work, and will undergo much to get off it, may we not hope that punishment may be found more deterrent? The best of it is, that the labour in these establishments has enough pecuniary value to make them at

length self-supporting. It would be well to give up such wasteful engines as the treadmill, and make all convicts contribute to the expense they entail on the country.

Cheap Ice.

THE spinal ice-bag has recently added one more demand for ice at an economical rate to those which our hospitals have experienced hitherto.

A new machine for this purpose, invented by Mr. Reece, has been under the investigation of the Society of Arts.

The principle of the apparatus is, to take advantage of the high latent heat of ammonia and of the other physical characters of that substance, with the object of abstracting heat from water or any other materials, so as to effect a considerable reduction of their temperature. The result is attained by allowing liquefied ammonia to vaporise in a close vessel, surrounded by the water or other material to be refrigerated, so that the heat requisite for the vaporisation of the liquefied ammonia may be taken from the material cooled. This operation is rendered continuous by applying the absorptive power of water for gaseous ammonia, so that the gas is dissolved as fast as it is produced, and the resulting solution of ammonia is pumped into a vessel, where it is brought in contact with steam at a high temperature, so that the ammonia is again separated from the water it was dissolved in and passed to a condenser, where it is liquefied, and then serves to replenish the refrigerator. One of the chief features of this apparatus consists in the use of liquefied ammonia, free from any admixture of water, with the object of rendering the ammonia more effective than it otherwise would be.

The result of experiments showed that the cooling effect produced by the consumption of 1 lb. of coal in the furnace of the generator was equivalent to the melting of 9½ lbs. ice, independently of the consumption of fuel requisite for the pumping of brine, ammoniacal liquor, and condensation water.

The mean rate of refrigeration, during the two days' experiments, amounted to a cooling effect equivalent to the melting of 128 lbs. of ice per hour.

The mean of the work done in the liquefier was at the rate of about 20 lbs. of liquid ammonia produced per hour.

It was resolved to report as follows:—

"It is the opinion of the Committee that the machine, as at present constructed, cannot be recommended for adoption. Mr. Reece has declined to make arrangements for carrying out the further experiments proposed by the Committee. They are, however, of opinion that, with certain modifications, the apparatus might be usefully employed for refrigerating purposes."

The German Scientific and Medical Association.

THE forty-third annual meeting was opened at Innsbruck on the 18th inst. The statutes of the association, embodying the object of its formation, were read, and these stated that "the main object of the association is to afford means of making the scientific men of Germany mutually acquainted with one another."

The Governor of the Tyrol, his Excellency Baron Von Lasser, then made a speech, welcoming the association in the name of the Emperor of Austria, and he was followed by the Mayor of Innsbruck, who gave a similar welcome in the name of the town.

Professor Dr. Helmsholtz, Privy Councillor, of Heidelberg, was then called upon to deliver his address. The subject he had chosen was "The History of the Development of Science in Later Times." Beginning with the discovery of the laws of gravitation, he traced out the progress of scientific discovery till the most recent date. The address was received with much applause. Professor Helmsholtz was followed by Dr. J. R. Mayer, of Heilbronn, whose discourse was scarcely audible to a large number of the audience.

After these addresses, the members of the association distributed themselves to their various sections. With true German love of detail, no less than eighteen sections have been made.

All the sections are accommodated in the various classrooms of the university, and as there is so great a subdivision of subjects, no large rooms are required.

Each section proceeded to elect its president, and the order of the papers for Monday, the 20th instant, was arranged. At one o'clock there was a general dinner, and in the afternoon a promenade to Berg Isel, a hill south of the town, which commands a lovely view of the surrounding neighbourhood.

Sunday was devoted to an excursion over the Brenner, which is really a trip worth making. The scenery is fine, and the engineering difficulties of crossing this Alpine pass have been most successfully overcome.

On Monday there were sectional meetings; on Tuesday sectional meetings and a second general meeting. The afternoon is to be devoted to a promenade to the Lanser Köpfe, two hills on the east of the town. On Wednesday the geologists make an excursion to the salt works of Hall, and there is to be a concert in the evening in the assembly-rooms. On Thursday and Friday the sections continue their sittings, and the final general meeting will be held on the latter of these days. This will conclude the work of the Association for 1869.

In the journal of the Association there were about 750 names, but as the names of the lady associates are not printed, the list does not show the total number of members and associates. In all it will probably reach about a thousand.

The Germans certainly bear away the palm from us with regard to early rising. The sections sit from 8 a.m. to 10 a.m., and have, therefore, finished their work before we begin ours in England. What is to be done for the rest of the day is a problem to be solved. The lodgings committee has done its work well, and there are no complaints about quarters or excessive charges.

Indian Cholera.

ADVICES from Akyab to the 1st August received in Bombay state, that cholera was raging to an alarming extent in that town and the districts, driving the population of whole villages from their homes, and preventing immigration from Chittagong, without which the cultivation of the rice crop has become an impossibility, and thus a large area of ground, formerly under cultivation year after year, is now lying waste. Official statements go so far as to state that there would be no rice for export at all next year, and that the whole of the grain sown would barely suffice for home consumption of the country. This is rather an exaggerated statement; but there is no doubt that from the above causes that, so far as Akyab is con-

cerned, the export of rice will be on a smaller scale than for several years past. The rains have been plentiful, but the effects of cholera, and consequent want of labour, have quite neutralized their effect.

The *Lucknow Times* says that some companies of the 62nd Regiment were sent away to Alumbagh under canvas, but regret to learn that even there several men were attacked by cholera, and succumbed to the attack.

In consequence they are being moved further on. Some six or eight persons of the same regiment were buried on the 6th ult., and about the same number the day before. Fortunately no other corps in the station has yet been touched.

Hospital Subsidies in France.

IN striking contrast to the attitude of the English Government in respect of our Hospitals, is the record of the improvements effected by the French authorities. In London it is true that private benevolence has relieved the country of the necessity of caring for its charitable institutions; but we believe it would not be an exaggeration if we were to assert that outside London almost three out of every four hospitals are restricted in their usefulness by heavy debts.

In Paris considerable sums have been spent by the town, by the administration of the Assistant Publique, and from the funds of the hospitals, in the following undertakings:—

1. The completion of the Laribosière Hospital, commenced under the Government of July.
2. The construction of the Hospital for Sick Children (St. Eugénie); a hospital at Berck-sur-Mer; the Maison de Rétraite, at Chardon-Lagache, and the foundation of the general hospital stores.
3. The re-construction of the Hôtel Dieu, now in course of execution.
4. The purchase of land for the new hospital at Menilmontant.
5. The removal and re-construction of the Maison Municipal de Santé, in the Faubourg St. Denis, and St. Pierre, at Auteuil; the hospital of Villas, at Issy, and another for incurables at Ivry.
6. The hospitals of St. Antoine and La Charité have been enlarged by the building of new wings, and a building for lying-in women has been added to the Hospital de la Pitié. Baths have been added to the hospital of St. Louis, and the hospital of Bicêtre and of La Salpêtrière considerably enlarged. A flour-mill and stores have been added to the Boulangerie Centrale.
7. A considerable number of old buildings have been restored.
8. The furniture, linen, and clothing at the various hospitals have been renewed and increased.
9. Twenty-eight new *maisons de secours* have been established, chiefly in the suburbs.

The number of beds in the various hospitals, which in 1852 was 6,743, is now 9,820, an increase of 1,077, without taking into account the 500 supplementary beds which are ready to be put up in case of emergency. In 1867, the number of sick persons who received medical attendance in these hospitals was 63,398.

The number of gratuitous consultations was 648,610, of which 329,521 were given in the hospitals, and 355,089 in the *maisons de secours*. The number of the beds in the asylums has also been largely increased, and are now 11,260. A special service has also been organised for attending sick persons at their own houses, and in 1867 1,137 persons received attention, namely, 427 men and 710 women.

STUDENTS are reminded that they must register at the General Council, Soho Square; and as the London College of Surgeons declines to receive such registration, those who mean to take that diploma must further register at Lincoln's-inn Fields.

TYPHUS prevails at Berlin and Vienna.

THE death of another centenarian was recorded last week.

THE foot and mouth disease prevalent in Middlesex has now spread to pigs.

THE Royal Hospital for Chest Diseases received last week a donation of £1,000 from W. P. D.

CHOLERA has carried off Senior-Assistant Surgeon Hale, of the Bombay Fusiliers, at Morar, Gwalior.

RELAPSING fever has appeared in London. Cases have been admitted into the Fever Hospital, and into King's College.

It is expected that the accouchement of the Princess of Wales will take place late in November or very early in December.

THE attendant of the unfortunate lunatic who was lately scalded to death has been committed for trial on a charge of manslaughter.

THE *Essex Standard* records in feeling terms the death of Dr. Allan Maclean, a really scientific man, sometime physician to the Colchester Hospital, but who had retired from active practice.

THE London Hospital College dinner takes place on the 1st October. That of University College on the 4th. The old students of St. Bartholomew's are to dine together on the 1st, Mr. Holmes Coote presiding.

HENRY EWEN, Esq., F.R.C.S., of Long Sutton, Lincolnshire, after forty years' active practice, died on the 5th inst. He suffered very much, organic disease of the stomach being the cause of death.

THE *Nottingham Express* announces the death, at the age of twenty-nine, of Mr. Forbes Watson, a surgeon who had gained the esteem of all his fellow-townsmen. The *Express* gives a feeling biographical sketch of the deceased practitioner.

AT the Mansion House last week, A. Bell, who said he was a surgeon, but whose name is not in the register, was fined 40s. for employing a man to post handbills in urinals. Cannot we put an end to this advertisement nuisance in this way?

THE Rev. Wm. Clark, M.D., nearly fifty years Professor of Anatomy at Cambridge, died on the 15th inst.

When he resigned his Professorship three years ago, a subscription was raised for the purpose of honouring the veteran Professor by placing his bust in the University.

MESSRS. JAMES, ROBERTS, GILBERTSON, and JONES, surgeons of Aberystwith, have written to the *Times* in vindication of the health of their pleasant town, about which, it appears, false reports had been circulated by those in-

terested in keeping intending visitors at other places. In a letter signed by all four, they pledge their professional repute to the healthiness of Aberystwith.

DR. RICHARDSON'S Lectures on Experimental and Practical Medicine, to which we have so often directed the special attention of our readers, will recommence on Tuesday, the 5th of October. The first lecture will be on the Physiological and Therapeutical Properties of Chloral.

At the suggestion of many who have attended and who wish to bear part of the expense of the experiments the very moderate fee of one guinea has been fixed for the course of six lectures. We can only wish the lecturer a larger class than ever.

AT an inquest last Thursday, held by Dr. Lankester, the jury returned a verdict in accordance with the medical evidence, that the deceased, a young woman of nineteen, who had fallen down dead in the street, died from "effusion of blood on the brain, caused by a fatty heart, accelerated by compression of the chest, produced by tight-lacing." How annoyed the *Lancet* must be at having missed this glorious opportunity for a sensation note on the "Waist of the Period!" We pity our contemporary, but then the young lady could not choose her time to die. Would next week be too late?

Correspondence.

ON THE CAUSATIVE AGENCY OF THE SKIN AND LIVER IN THE INDUCTION OF PHTHISIS AND OTHER SCROFULOUS MALADIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In reply to the criticisms of "Constant Reader" in your issue of September 1st, I beg to say that, in the present state of our knowledge of phthisis, I do believe we are warranted in resorting to the trial of any remedy not harmful in itself. I do say that up to the present year of grace, 1869, consumption is one of the "opprobria medicinæ;" and well assured am I that the cheek of your correspondent would grow pale if he were to learn that anyone near and dear to him was attacked by phthisis, even though he could summon to his aid the most skilful and scientific physicians in Europe.

My critic informs me that lemon-juice has been tried, and found only to hasten the progress of phthisis, for which information I am duly grateful. Had I suggested its use on the ground that oxygenating agents were the remedies "*par excellence*" for consumption, I might have been mortified by this contradiction to my theory, since lemon-juice and citric acid are rich in oxygen; and, if I mistake not, Barlow, in his "Practice of Medicine," ascribes the utility of lemon-juice in acute rheumatism to its oxygenating properties; but it is Dr. Mulvany who asserts that oxygenating remedies cure phthisis, not I.

Your correspondent says that Dr. Pavy has shown the glycogenic function of the liver to be a myth. Now, my paper, or at least that part of it in which I speak of the glycogenic functions of the liver, was printed in the *Dublin Quarterly Journal of Medicine* for August, 1863, two years before Dr. Pavy's denial of the glycogenic functions of the liver.

But, though Dr. Pavy denies the glycogenic function of the liver, that is to say, that the liver makes sugar under its ordinary physiological or healthy conditions, he does not deny that under certain pathological or morbid conditions, glycogenesis does take place in the liver, "the sugar being," he says, "formed by an unnatural transformation of amyloid substance in the liver."

In my paper, I presumed that a morbid action of the liver preceded phthisis, which is probable, and that excessive, or, as Dr. Pavy would term it, "unnatural" formation of sugar

took place. If Bouchardat's statement be correct, that "diabetes always precedes phthisis," I am probably right in this conjecture.

But it is rather unfair of my critic to talk of my building up a theory upon the glyco-genic functions of the liver, as if that was the substance of my paper; whereas, alluding to the significant presence of fatty liver in phthisis, always mentioned by pathologists, but not even sought to be explained, I suggest that it impedes the secretion of bile, and causes either constipation or diarrhoea, according to the degree of intestinal congestion induced, and that it hinders or perverts the manufacture of liver-fat, possibly rendering the fat formed unfit for deposition in the cellular adipose tissue, aiding in cytogenesis, calcification, &c.

I dwell much upon the acidity of the blood; and, after enumerating its many other mischievous effects, videlicet, preventing oxydation, hindering the absorption of iron into the blood, favouring congestion, and the deposition of lymph, and transudation from the blood-vessels, I remark that it would hinder the saponification of fat which takes place in healthy blood, and call attention to the fact that the blood is loaded with fat in phthisis, whilst the patient is emaciated.

I have endeavoured to account for this production or rather presence of acid by suggesting that it is due to imperfect action of the sudoriferous glands, whose function it is to eliminate acid.

I do not say that scrofula and tubercle are identical, but I do regard one as the fruit, of which the other is the tree. Some trees are barren; and the scrofulous diathesis may exist and yet no tubercle be formed.

A true appreciation of the pathology of disease will be the best guide to the treatment. Do the results of Dr. Mulvany's or Dr. MacCormack's treatment of phthisis show that they, beyond other members of the profession, have attained this true appreciation of it?

I have re-perused Dr. Mulvany's brilliant and gracefully-written paper on the "Rational Treatment of Consumption," in the MEDICAL PRESS AND CIRCULAR for April, 1867, but I cannot say that I am convinced of the truth of his theory, or satisfied with his proofs of its successful application.

To quote the words of Dr. Savary, "Many drugs, rich in oxygen, have been given under the idea that they would furnish this element to the blood. But it need hardly be said that this idea, which has arisen out of a misconception, is, for the most part, purely visionary. In the first place, it has not been shown that these compounds yield free oxygen in the blood; and even if they were so decomposed, the amount of oxygen they could furnish would be trifling to that always taken in by respiration."

The permanganate of potash, which is the remedy of all others, according to Dr. Mulvany, is so readily decomposed by contact with organic matter, that I think it would, given in the doses he directs, be decomposed by the fluids of the mouth, pharynx, and stomach, and, if so, become disabled from conveying oxygen to the blood.

Dr. Mulvany says, "After four days, I recommended half an ounce of cod liver oil to be taken three times a day, with the permanganate of potash." This may be only a slip of the pen, as of course Dr. Mulvany would not, wittingly, repeat the blunder of a late eminent physician, of exhibiting oil or sugar or any organic substance with the permanganate, which they at once decompose.

The two cases reported by Dr. M. as cures effected by the permanganate, seem to me to have been probably cases of chronic phthisis, such cases often improve under any simple treatment, or none at all; but they are liable to relapse, and eventually merge into chronic bronchitis. The first patient is said to be cured in one month! The second having been sufficiently recovered from a first attack to be discharged to duty, is cured of a second attack by the permanganate, in addition to other remedies nevertheless required to be invalidated from the service!

With regard to Dr. MacCormack, who considers pre-breathed air as the *fons et origo malis*, and who, following up his theory, directs the bed-room windows of phthisical patients to be kept open at night, I have to remark that birds, whose respiratory apparatus is very perfect, and who consume much oxygen, put their heads under their wings at night, shewing that such pure air is not required by night as by day, and that warmth is necessary to promote sleep. Whilst admitting that good ventilation is very desirable, I think the admission of night air to the bed-room of the phthisical patient (unless

in very fine weather) likely to be attended with bad consequences.

I am, Sir, your obedient servant,

Sept., 1869.

FRANCIS M. LUTHER, M.D.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I thank you for your opinion on the character of the wealthy gentleman who offered me a fee of four guineas for a consulting opinion, after travelling eighty miles, at special telegraphic request.

It is, certainly, open to me to enter an action, but time and money would be thrown away in the matter. I think most members of the profession, holding certain positions, are perfectly well aware what *value* judges, lawyers, and juries, as a rule, estimate us at.

I do not hesitate in saying there are, in my opinion, and sorry to say so, plenty who would have jumped at four guineas, where I expected at least forty. I shall suggest to the wealthy gentleman the *saving* the next time when he wants plenty for his money, should he be sick. Truth is a libel, or I would give the profession the public name and address of the wealthy city merchant trader as a caution.

Yours truly,

22nd Sept., 1869.

M.D., M.R.C.P.

P.S. It is a great pity the profession have not a legal scale of fees for operating surgeons, general practitioners, and consulting physicians. Any fee over should be accepted as a compliment to the professional man himself, and if all agreed not to take less, union would strengthen, and the public would respect us.

Gleanings in Medicine, Surgery, and the Allied Sciences.

DIAGNOSIS OF DISEASE OF THE SPINE.

Dr. Chas. F. Taylor contributes to the *N. Y. Med. Journal* an instructive paper on the above subject, based upon an experience of ten years and upon a systematic record of all cases under prolonged observation since May 1, 1866. This record shows 382 cases of Pott's disease of the spine. Dr. Taylor desires to impress upon his readers the advantages of early diagnosis, before the occurrence of deformity—"the necessity of always keeping in view that the deformity is not the disease—that the disease must have existed long enough to cause a certain amount of destruction before deformity can occur." The disease is usually inflammatory, not more than one case in fifty or a hundred being of tubercular origin. If not stopped it may eventuate in caries and perhaps in tubercular deposits also. In no one instance of the entire number of cases recorded, was there any hyperæsthesia along the spine, therefore palpation and percussion of that region is useless. The first symptom, if the disease exist in the lower dorsal or lumbar vertebrae, is persistent pain in the abdomen—gastralgia; if the dorsal vertebrae are affected, there is pain in the chest and a peculiar cut-off respiration. A very important point to observe is the attitude of the child. This is characteristic. He does not always lean to one side or the other, though frequently doing so; but there is an expression inimitable and easily detected, an effort to get as many springs under him as possible; a letting down of each joint of the body so as to avoid shock. When the child comes to his mother's lap he will fall heavily upon it, and wish to bear his whole weight on his elbows. When in the cervical region the disease may be taken for torticollis, contraction of the psoas muscle may cause it to simulate hip-joint disease, but in the former the body is drawn down, the patient inclining to support himself with his hands on his knees, while in the latter the thigh is flexed on the pelvis. Again, in the former, when the patient is placed on his back both legs may be rotated, abducted, &c., without pain. Another symptom of Pott's disease is paralysis, which in the early stages may last but a few days, but later, continue one or two years. The so called "spinal irritation or backache," so common in delicate adult women, is nearly always due to other causes than spine disease. In fact, the presence of hyperæsthesia is generally a

good sign that there is no inflammation of the vertebræ. After illustrating the points of diagnosis by two cases, Dr. Taylor says: "I wish to impress all those within the sound of my voice and all those whom my words may reach, with a sense of their responsibility in these premises. Cases are coming to me from this city, and from all over the land, which can never be anything but miserable deformities, because the disease which gave early, persistent, and painful warning of its existence, was never detected."

EXCESSIVE SECRETION OF THE LIQUOR AMNII, PRODUCING
PREMATURE LABOUR.

Dr. R. W. Dunlap reports (*Richmond and Louisville Medical Journal*) the case of Mrs. H——, age 38 years, the mother of eight children and previously enjoying good health, whom he found breathing with difficulty, pulse 100, tongue covered with a white coat, bowels rather torpid, &c. The abdomen was distended seemingly more than at full term, and was slightly tender. The patient stated that she was not more than six months pregnant, that everything had gone well with her until three weeks before, when she began to enlarge rapidly, and that she found it difficult to breathe when lying down. Palpation and percussion gave no sense of fluctuation. Dr. Dunlap's treatment was directed to the bowels and kidneys, to increase their action, notwithstanding which the symptoms became aggravated, and in the night of the fifth day while sitting at stool, the water suddenly gushed forth, filling the vessel, then a large washbowl, which finally overflowed, wetting the floor for a great space around. The amount of liquor amnii was estimated to be between four and six gallons. In a few minutes two fetuses were born, weighing two and a-half and three pounds. They had apparently been dead several days. The placenta was single and excessively large. There were no after pains, nor was there any flooding. Dr. Dunlap refers to several cases mentioned by writers, in which there was an excess of liquor amnii even amounting to forty or fifty pints. Contrary to what might be supposed, in no instance did he find that flooding followed delivery. On account of the overwhelming probabilities against the fetuses being born alive, he agrees with Ramsbotham and others, that when a correct diagnosis has been arrived at, the membranes should be punctured and the superabundant fluid evacuated.

RICHMOND, WHITWORTH, AND HARDWICKE
HOSPITALS, NORTH BRUNSWICK-STREET,
DUBLIN.

THESE Hospitals contain 312 beds, always available; and we regret that they should have been inadvertently omitted from the list of Dublin Hospitals in our "Students' Number."

The particular advantages of this Institution may be learned by reference to the Advertisement, page xxv. of the "Students' Number."

Medical News.

STRANGE SENTENCE OF DEATH.—The Home Secretary has a good opportunity of reprieving the sentence of death which has been passed on several innocent persons by simply exercising his functions in a useful and unobjectionable manner. At a late meeting of the St. Luke's vestry the medical officer reported, under the Artisans' and Labourers' Dwellings Act, that certain huts or shanties in Wood's place, Chequers alley, were unfit for human habitation; and the vestry clerk remarked that the vestry was empowered to shut up the premises and keep them closed until they were put in a proper state of repair. Thereupon it was pointed out by several vestrymen that if they carried out the provisions of the Act they must employ several additional officers; and that if they put the premises into a proper state of repair an expensive machinery would have to be put in force. The clerk, however, explained that if the vestry failed to carry out the provisions of the Act, the Home Secretary would cause them to be carried into effect and charge the expenditure to the vestry; and Mr. Adams remarked that if after the receipt of the medical officer's report an outbreak of fever occurred in the neighbourhood, the vestry would most certainly be held responsible to a great extent. Some of the vestrymen were in favour of proceeding under the Nuisances Removal Act; Mr. Daniel suggested that the mat-

ter should be allowed to stand over for a month, and that meanwhile each member of the vestry should be furnished with a copy of the Act, so as to become master of its clauses. After a long discussion the matter was referred to the sanitary committee, and copies of the Act were ordered for the vestrymen. It does not seem to have struck this enlightened Board that perhaps the threatened fever may not consent to "stand over for a month," and may become master of the neighbourhood while the vestrymen are mastering the clauses of the Act referred to. We are well aware that the victims of this delay have no real claim on the Home Office. They have not murdered each other under circumstances of peculiar atrocity. If such had been the case, no appeal would be necessary. It is only a poor neighbourhood threatened with mortal illness and afflicted by a vestry; but if the law gives the Home Secretary power to help them, perhaps for once he will kindly do so, notwithstanding their innocence and the indignation of Bumble.—*Pall Mall Gazette*.

TOBACCO.—It is satisfactory to hear that M. Armand, a French savant, has stated to the Academy of Sciences that he has discovered a sure antidote to nicotine in the common watercress. It destroys the poisonous effects of nicotine, and yet does not alter the aroma of tobacco. A solution of watercress may therefore be employed for steeping the leaves of tobacco, and would thus divest them of their noxious properties, and, moreover, a draught of the same will act as a sure antidote to nicotine. In the face of this important discovery, anti-tobacco societies will no longer have any excuse for the affectionate interest they have hitherto displayed in the health of smokers, or for the lavish abuse they have so freely bestowed upon their victims. Instead of tracts, the anti-tobaccoists should now distribute watercresses, and we feel sure that Dean Close will be the first to set a good example by encouraging the growth and promoting the circulation of this now truly valuable plant.—*Pall Mall Gazette*.

ROYAL ORTHOPÆDIC HOSPITAL, 315, OXFORD STREET.—The half-yearly Court of the Governors was held at this hospital yesterday, Mr. Henry Walker, V.P., in the chair. The statistical report, read by the secretary, stated that the number of patients admitted during the last half-year was 985, being 276 more than in the preceding half year, and making the total number benefited since the opening of the hospital 44,256.

ROYAL MEDICAL COLLEGE, EPSOM.—St. Bartholomew's Hospital, Charing-cross Hospital, and University College Hospital have awarded free medical scholarships to the Royal Medical Benevolent College, Epsom. The two former are without endowments, whilst the latter (University College) has one scholarship endowed with 50*l.* a year, and tenable for four years. Other endowments are to be established as soon as the necessary funds can be obtained. The trustees to this Free Medical Scholarships' Fund are Dr. Carr, Dr. Ringer, and Mr. John L. Propert, who will receive contributions. The principal contributors, so far, are, Sir James Clark, Sir Thomas Watson, Sir Charles Looock, Sir W. Jenner, Dr. Burrows, Mr. James Paget, Mr. Simon. Dr. Carr has given 1,000*l.*

NOTICES TO CORRESPONDENTS.

In all cases when proofs are sent, it is of the utmost importance for them to be immediately returned.

CORRESPONDENTS not answered should look to the answers the following week.

TO SUBSCRIBERS.—Those gentlemen who have not paid their subscriptions for last year are respectfully reminded of the omission.

"Ox a new Preparation of Pepsine, by Edward Long, L.A.H.," received.

Dr. JOHN MARTIN.—Your "Notes on some Cases of Erysipelas" are in type for an early number.

Dr. LUTHER.—Certainly.

Dr. DRYSDALE's letter from Paris is unavoidably postponed.

Dr. PALFREY's concluding Lecture has been unfortunately delayed from indispotion. It will shortly appear.

A LONDON HOSPITAL MAN.—There will be a dinner after the Introductory on Friday.

STUDENS (St. Bartholomew's).—The question is treated in another column. The students will meet on the first. You should attend.

CHEMISTS.—See the special report on Students' Text Books (No. I.) in our last issue.

AUTHOR.—We have not seen your book. If forwarded in the usual way it will be noticed.

LARGE FAMILIES.—F. L., in reference to the extract forwarded by W. C., and inserted last week, wishes to express his concurrence, and to an indignant protest against the use of such terms as "diabolical" the substitution of which for "dialectical" he considers as "devoid of wit," as it is a "breach of good manners." He adds that "a professional gentleman should be above personal abuse and misrepresentation."

Dr. MOORE.—If possible in our next.

SEVERAL Letters are unavoidably held over.

The Medical Press & Circular.

Introductory Lecture

DELIVERED AT THE
LONDON HOSPITAL MEDICAL COLLEGE,

OCTOBER 1ST, 1869.

By C. MEYMOTT TIDY, M.B.,

Joint Lecturer on Chemistry at the London Hospital.

TO-DAY, Gentlemen, is a day for old and young to meet, though the one turn his back upon the other; for old to look back, for young to look forward. Age may look back, indeed; to-day—sad, serious, sober; how long it has laboured, how steep and up-hill its path, how weak and nerveless its mightiest effort, how small its reward has been! Yet, maybe, it is not all so sad. Strong, deep marks it may see left behind it—steps which its own hand has cut—a ladder for its sons. No formless, shapeless grooves, but a mould of beauty, passion, and of strength; and though its hand tremble now, and its eye be dimmed, yet a good conscience is its joy, and a faith in the future its possession.

Nor is it a little joy for the old to turn back in love and sympathy for his sons, to tell his children of the rough rugged paths which have been made plain, of the old hard fight which is victory now, of the struggle whose crown is triumph. Nor does he envy the son who begins where he left off; for the child of Science is begotten at his father's grave.

It were a happy meeting here to-day if it did nought but cherish the love of a father and the worship of a son. We may be quite sure of this, that it is only as bowed down in reverence before the spirit that is past and dead that we can become the children of a living progress in the future.

And so we cluster around to-day as it were a life's halting-post, according to good old custom, to renew old acquaintanceships and old recollections of times gone by, to recount to old fellow-students our failures and our

triumphs, to be spurred on to greater activity by the recital of an old friend's successes, or to be warned of thorny and treacherous paths, perchance, by the recital of an old friend's mistakes; and not the least pleasant part of to-day is to see once more the familiar faces of those from whom, years ago, we learnt many a good lesson that has played, and is playing, its part in the work of our life.

Do not our thoughts travel backwards to-day to recal those great names once associated with our School and Hospital—men who have left their foot-prints on the sands of time, indelible marks on a page of the history of medical science? And it is right on these occasions to recal them. We scatter the seed and plant the ground, but they tilled and raked it; though dead, yet they speak. We can never forget what our science owes to men like Richard Headington, Sir Wm. Blizard, Thomas Davies, and Jonathan Pereira. Having fought a hard-won battle, having run their course and done their work, and having trained others to take the place they so successfully filled, they laid down their weapons, tired of the load; and it may be they are with us to-day, hovering about this very theatre, approving our doings, and, in some strange manner, lending a helping hand.

And, again, there are those, too, present to-day who are preparing to follow them, but are content to wait a little while, until the summons arrives for them to leave a life of toil and labour for the land where the weary are at rest.

And, again, there are those present who are in the thick of the battle with those terrible foes of our race, Death and Disease; constantly on the watch for any new mode of attack—for, alas! how constantly do they vary their tactics—and then ready and eager to adopt new plans and fresh measures for counteracting their cunning manœuvres; day and night facing the foe in the chamber of the sick, and, if baffled in their efforts, and conquered once by death and his legion, counting no cost too great or labour too severe to hunt out, if possible, its strength and their weakness by cautiously examining the ground, step by step, in the *post-mortem* room, lest he try the same devices again, as, having been successful once, you may be sure he will.

Again, some there are amongst us to-day who join us for the first time, and, in the name of the Council and Lecturers of this School, I earnestly and cordially welcome you to our midst. It is good for you to be here; and yet we trust you have not come by any mere accident to commence what I must honestly tell you is a laborious career, which you had better never have chosen unless you come with the plain straightforward object before you of fitting yourselves to bring all that science can possibly suggest for the relief of a suffering humanity. A day of retrospect will come in this world, and a day of reckoning in the next; and let me say, if you fail to administer that relief from any lukewarmness on your part, or from any neglect in noting the practical business of your Profession, it were far better that you had never known to-day; for you will have to bear the brunt of a conscience that will be constantly telling you that lives, more precious than silver and gold, have been lost through your want of skill; that misery has been brought on many a family as the result of your previous neglect; that the enormous capabilities fortune has entrusted to you of doing good have been actually converted by your own most grievous fault into opportunities of doing evil. Oh! it were ten thousand times better that you had never known to-day unless you are determined to lay aside all that would divert you from honestly fulfilling those engagements—those sacred engagements you are now making to be bound with more than marriage ties—ties which death, and death only, can sever—to that Profession which will have no divided allegiance, but the man and the whole man. For to-day you put your hand to the plough,—it will be a sorry day for you if you ever dare to look back.

It is this medley assembly I see before me to-day that has suggested one thought to which I would desire to draw your attention, deeply regretting that the task of dealing with it falls, not by my own seeking, but at the request of the Council, on one who cannot claim your attention on the ground of experience, and has, therefore, to trust, though with considerable diffidence, to your kind and courteous forbearance; and, what is most unfortunate of all, I have of necessity to travel over ground that has furnished, times out of number, materials for eloquence and for powers far more forcible or commanding than any I can possibly pretend to lay claims to.

And do you not think it right and proper that we should now and then try to see the influence of past investigation on present discovery? That we are wiser than the ancients I admit; but only wiser because the knowledge they amassed served as a nucleus for our work. If we had to commence anew, we should not be one whit wiser or sharper than they were. In short, to sum up in one word, scientific investigation is a history of development. You sadly mistake the truth if you suppose we owe all the great discoveries of modern times to one or two individuals. No! Depend upon this, if you would know the truth, you must go back and hunt up each little discovery that was first perhaps unheeded, or only put upon record on the page of a dusty manuscript, but which yet served as the foundation of more extensive experiments and more elaborate research. Take an instance of what I mean. There are some who are tempted to laugh at the absurd doings and experiments of the alchemists; they picture to themselves either a set of rogues or a set of fools. There may have been some of the one class, as I am certain there were some of the other. But of this I feel confident, that we could never stand here to-day and tell of the mighty achievements of modern chemistry, aye, and modern medicine too, had it not been for the patient indefatigable work of these ancient pioneers of science. You tell me of their follies. You see a man who deems no hours too long, no labour too severe, to hunt after some mysterious powder by the agency of which he supposes he may be enabled to transmute the baser metals into gold. You smile as you read page after page of what you deem unmitigated folly; but you surely forget how much you are indebted to these

seemingly absurd experiments for our acquaintance with various metallurgical operations, and the nature of metallic deposits. You see a second labouring to obtain a universal solvent. You laugh at him; yet you forget that, after all, diamonds and other gems have surrendered to the chemist their adamantine strength, and that you are indebted for the discovery of sulphuric, nitric, and hydrochloric acids to these very experiments you ridicule. You see a third trying to distil a vital elixir, by the action of which life may be prolonged indefinitely. You say this, at any rate, is the height of folly, of absurdity, of arrogance; but do not forget what a host of medicines were the discoveries of the alchemists (amongst others I need only mention antimony and mercury and their salts)—medicines which, when administered by those accustomed to the nature of disease, and wrested, as they should be wrested, from the hands of miserable quacks and impudent charlatans, have, after all, soothed many of the ills that flesh is heir to, and, I am bold to assert, have prolonged in no slight degree the average term of human existence.

Now, it will be well, I think, in tracing this principle out to its full extent, to select a few illustrations, as instances of how our present refinement is but the result of this great process of development. Take first, as an example, the history of that great operation of Lithotomy.

The first account of the operation on record is that given by Celsus, and which was in use exclusively down to the sixteenth century. He directs that a clyster should first be used, after which the patient was to walk about the room for some time to bring the stone down to the neck of the bladder. He was then to be supported on the thighs of two assistants, so strapped together that they might hold him between them, each having charge of a thigh. The operator was then directed to cut down at once, and the stone was to be extracted with a hook. This operation was known as "cutting on the gripe," or the operation by the "apparatus minor," to distinguish it from the operation by the "apparatus major," first proposed as an improvement on the last by Johannes Romanus. It received its name from the multiplicity of instruments employed (*Operation par le grand appareil*); indeed, the early surgeons seemed to suppose that the more elaborate the apparatus the more successful would be the operation. Modern science teaches, "the simpler the better." I can scarcely describe the terrible cruelties of the operation. Hippocrates taught "that cuts of membranous parts are mortal;" any and every means were therefore adopted to tear open the neck of the bladder with instruments a veterinary surgeon would not think now-a-days of using on a horse. Yet in some points we trace a gradual improvement in the details of the operation. Marianus Sanctus, the pupil of Johannes Romanus, recommends that the patient be placed on a table with his shoulders raised, his hands bound to his feet, the latter separated by two assistants; and for the first time we meet with a grooved staff. For 177 years this operation was in vogue, until Frère Jacques pointed out to the French surgeons the terrible nature of their pet operation, proposing, in the place of dilating instruments, the use of the knife, guided by the grooved staff; which operation must be regarded as the foundation of the highly developed method of perineal lithotomy practised in the present day. The success of Frère Jacques seems astonishing, considering his extreme ignorance, in the first instance, of all anatomical detail, and of the dangers of the operation he so boldly performed. We are not astonished, deeply as we deplore it, at the miserable jealousy of the French surgeons of that date towards one who laboured with such a unity of purpose and purity of design for the relief of the sick and poor around him, never accepting more for his services (so we are told) than was necessary to mend his shoes or sharpen his knives. And do you not see how the work of these early surgeons laid the broad foundation on which was afterwards built the reputations of Cheseldon, Sir Cæsar Hawkins, and Liston in this

country, and of Rau and Dupuytren on the Continent? Do you not see how these operations, much as you may despise them, barbarous as you call them, paved the way for that beautiful and delicate operation you so often have the privilege of seeing performed by no second-rate hands in the operating theatre of this Hospital? Lithotomy, then, has a history of development. The growth was slow, but it was sure.

But I would venture to draw your attention, at somewhat greater length, to an illustration of the same great law in connection with a branch of science to which I have given more special attention,—an illustration that will suggest to us the endless nature of development. There is no end to it, or rather, I should say, the world's end is its end. Fully conscious that much is beyond human ken, "to be known only when we know as we are known," at any rate the record of scientific progress spurs us on to labour in this our day, so that, if possible, we may add a stone to that vast structure, the foundation of which was laid by the ages gone by, and the completion of which is left for the ages to come. Not to care for posterity is a principle as far removed from common honesty as it is from common justice. You profit by the labour of generations past, and generations to come will profit by yours. Arrange then, I pray you, your work for to-morrow, though you may never see to-morrow.

It was in the year 1675 that Sir Isaac Newton presented the Royal Society with his remarkable treatise on "Optics." With strange humility he commences by speaking of his own deficiencies, figuring himself in words that have since become classical as "a child picking up pebbles on the sea shore." But, oh! what a wonderful child it was picking up the pebbles, and what wonderful pebbles they were the child picked up! Never let us forget that you and I are standing on the same beach now. It is a strange fact that, gather as you will the productions cast up with such lavish prodigality, the acquisition is not to be regarded as any diminution of the treasures that remain. Much as Newton discovered he left plenty for others.

In this paper he described his experiment of passing a ray of sunlight through a triangular piece of glass, called a prism, when, instead of white light, he obtained a band of seven different colours, blending in beautiful harmony from red to violet, produced, as he showed, by the unequal refrangibility of the several colours. Further, he proved this splitting up could only be effected once—I mean, *e.g.*, the red remained red, and the yellow yellow, no matter through what number of prisms they were respectively passed. And once again, he showed that these seven colours blended together produced white light. Thus, analytically and synthetically, he proved the compound nature of white light, and though in some details modern physicists doubt the accuracy of Newton's reasoning and deductions, none question the rare power that suggested the experiments.

It was in the year 1802 that Wollaston noticed that upon admitting a ray of sunlight through a vertical slit, parallel to the sides of the prism, the spectrum produced was not perfectly continuous, but crossed at right angles to its length by dark bands, which dark bands were not present in the spectrum from the electric light. And now note how Wollaston reasoned respecting the nature of these dark bands. Upon counting them he noted seven, the exact number of colours in the spectrum, and immediately he jumped to the conclusion (not an unnatural one by any means) that these seven dark bands divided the seven colours of the spectrum into seven parts. I do not think Wollaston made any further experiments, nor did they, from what I can gather, attract the smallest amount of attention from the scientific world.

In the year 1814, Fraunhofer, a celebrated chemist residing at Munich, rediscovered these lines, and from that time to this, on account of his elaborate researches, they have been called after Fraunhofer, although, so far as mere priority of discovery is concerned, the honour belongs to

Wollaston. It is strange to note in the history of development, how often two men seem stirred to work at or about the same time at the same thing. It is a mysterious though a natural law that no great discoverer is ever vastly ahead of his contemporaries. There are always a number of persons whom he barely anticipates, moving in the same direction towards a similar goal, but of whom he just contrives to get a fortunate start. It does not matter, however, whether the race be won by a head or a length, or ought it to diminish one whit our tribute of respect to the winner. But what conclusions did Fraunhofer arrive at concerning these lines? He found that none of them did correspond with the boundaries of the coloured spaces as Wollaston supposed, and that, instead of seven lines, he made out no less than 576, the relative position of which he drew a map of. And he further noted this, that these lines always occurred in solar light, whether it was direct or indirect, but that when he examined the fixed stars, he was immediately confronted with a new set of lines, and that whilst the light from Mars and Venus gave the same lines as sunlight, those from Sirius, Castor, and Procyon differed in many important particulars. This, I think, was about the extent of Fraunhofer's experiments. Nor does it seem that he reasoned to any great extent upon them. He was content to gather together an army of facts. But thus much he adduced:—1st, That starlight differs essentially in its qualities from sunlight; and, 2ndly, That the dark lines were produced somehow or another in the sun itself, a conclusion I shall show you directly is confirmed by all subsequent observations. How slowly truth grows! "First the seed, then the ear, then the full corn in the ear." It is error that springs up apace, and spreads itself with lavish hand, here, there, and everywhere.

In the year 1822, Sir David Brewster and Dr. Gladstone examined the spectra produced by flames, coloured with various substances. They remarked that in these cases they could only obtain one or more coloured bands, whilst the remainder of the spectrum was wanting, showing how the light produced by gaseous and vaporous bodies is only brilliant in a few channels, husbanded and limited to a few lines. And they further suggested the possibility of deciding what a substance might be, by the character of the localised band.

Ten years after this (1832) they examined the spectrum from solar light, having allowed it to pass before it fell on the prism through the vapour of nitrous acid, when they noticed certain dark lines which they at once concluded were due to absorption of certain parts of the light. The following year (1833) Miller, of Cambridge, and the late Professor Daniel, ascertained that dark lines in different positions of the spectrum were obtained when sunlight had been allowed to pass through bromine, iodine, and euclyorine. Two years later (1835) Wheatstone, examining the spectra of the electric light from different metallic points, observed that different metals gave different lines of light, the spectra not being continuous, and he remarked that the appearances were so remarkably characteristic that by this means the metals might easily be distinguished. Various physicists more or less distinguished devoted considerable time to the elucidation of these remarkable spectra, but it was not until 1859 that Professor Kirchhoff gathered together into one the whole of the experiments, reasoned upon them with rare philosophic accuracy, and applied these hitherto unapplied facts to the examination of terrestrial matter. He showed how by placing the smallest trace of an alkaline or alkalino-earthly metal in a hydrogen flame and examining the spectrum produced with a spectroscope, he was enabled to detect quantities that had hitherto eluded the finest balance or the most perfect test. The one-millionth of a grain of copper is easily detected. The 1-160 millionth of a grain of lithia (by which means it may be detected in rocks, rivers, milk, blood and muscle) and the 1-180 millionth of a grain of soda will at once yield characteristic bands that reveal their presence. By noticing the existence of lines they had never seen before Bunsen and Kirchhoff discovered two new metals in the

residue of some waters from Durkheim, in Rhenish Bavaria; and Mr. Crookes, in 1862, upon examining the sulphur from some Spanish copper pyrites, discovered a magnificent green band, such as no known substance produced, and which led to the discovery of the new metal thallium; and but a few months since, one whom I feel it no slight honour to call my good friend Mr. Sorby, of Sheffield, announced the discovery of another metal, to which he has given the name of jargonium, from his having found it in certain specimens of Ceylonese jargonite.

But this is not all. I have referred to the power that gases possess of absorbing various parts of the spectrum. Now, liquids have this power too, and as, in the case of gases, noting that certain liquids only absorb a certain part of the spectrum not absorbed by other liquids, in short, that each liquid absorbs its own part of the spectrum, we are enabled to employ this curious action as a means of detecting mysterious chemical changes taking place in the human body. Take, for example, the case of blood, the optical properties of which have been examined in 1862 by Hoppe, in 1864 by Stokes, in 1865 by Sorby, and in 1868 by Herapath.

Stokes, in 1864, showed that both venous and arterial blood contained a substance he called *crucorine*, which was capable of existing in two states of oxidation, the colour being different with each. They are examined thus: an excessively weak solution of the blood is placed between the light and the slit of the spectroscopy, when, in the case of scarlet *crucorine*, or, I will call it, the *crucorine* of arterial blood, two sharply defined black absorption bands are visible, whilst with the purple *crucorine*, or the *crucorine* of venous blood, produced by acting on scarlet *crucorine* with deoxidising agents, and not due, as can be clearly shown, to the presence of carbonic acid, there are no longer two absorption bands, but only one, taking up the whole of the yellow and part of the green rays of the spectrum. Now, it has been found that *crucorine*, when it has been dried, or exposed to air, or acted upon by sulphurous or other acids, becomes changed into a brown substance, called *brown hæmatine*, which, upon examining it with the spectroscopy, produces two absorption bands, like scarlet *crucorine*, but differs from it in producing a third absorption band in the red ray; and, further, by the action of some reducing agents, as the hydrated protoxide of iron, brown hæmatine is changed into red hæmatine, which produces two bands like scarlet *crucorine*, but which are easily distinguished from the *crucorine* bands by their position and degree of intensity. And now mark the importance of all these facts; by the spectroscopy, the merest trace of dried blood, no matter of what age, is without much difficulty discoverable. And to have such unquestionable means of detecting blood is, I need not say, a matter of extreme importance to those engaged in medico-legal investigations, enabling us with no hesitating voice to assist a jury to judge a righteous judgment, either to clear the innocent or to convict the guilty. A thousandth of a grain of dried blood is quite sufficient to produce all the results; and Mr. Sorby, who has devoted a life as a labour of love to these remarkable experiments, and to whom science owes a debt of the deepest gratitude, asserts he can obtain the absorption bands with a single half globule of dried blood.

What an astounding illustration this of the development of discovery! The physician may be able to discover the presence of blood globules in saline fluids, in urine, in saliva, and the generality of mucous discharges, by the aid of the microscope; and, provided the fluid in which they are suspended be of equal specific gravity to that of blood serum, their form and size may then be determined, and their probable source as well. But, how useless the microscope often proves itself when the blood is dry, on account of the difficulty of restoring old globules to their old form! And then the chemist is appealed to to detect possible albumen and destruction of colour by the agency of heat, or non-destruction of colour by the action of ammonia. And yet, delicate as these tests are, how often we fail from the small quantity we have to examine! The spectro-

scope demands attention to one point, and that is that the solution operated upon should be sufficiently dilute.

Let me, however, point out that, startling as are the results of discovery, there is one thing as yet we cannot do with the spectroscopy, and that is to discriminate human blood from that of other mammals. It may be, gentlemen, this discovery is reserved for some of you who are with us to-day for the first time, or it may be these little wantings are to teach us that there is a distinct limitation to scientific research. So far, but no further, or else you overstep the boundary, and the creature would usurp the power and authority of the Creator. Finite can never thoroughly understand the work of the infinite. There is a limit to all our positive knowledge. The greatest power is to see it—the greatest wisdom is to confess it.

I am desirous of taking you one step further, and to show how we are enabled to stretch our hands beyond our earth, and to gain certain information respecting the constitution of the sun and far distant stellar worlds—how, in short, we can analyse the atmosphere of the sun as certainly as we can that of our own planet. The glory of these discoveries in the first instance belongs to Professor Kirchhoff. They have received considerable attention of late. Amongst others De La Rue, Huggins, Norman Lockyer, and Father Secchi, especially deserve mention. I may briefly describe the experiment which led to Kirchhoff's brilliant discoveries. He noticed that the yellow lines produced by sodium coincided with one of Fraunhofer's dark bands (D), and also that the bright lines from other bodies were in exactly the same position as other dark lines. He was examining the yellow line from sodium vapour in a Bunsen burner, when he allowed solar light to fall through the flame, when, instead of the black line corresponding with the bright line becoming less distinct, it became infinitely more distinct. He then placed the oxy-hydrogen light behind his yellow flame, when he found the dark band instead of the bright line. He thus arrived at this great fact—that luminous sodium vapour has the power of absorbing the very light it itself gives out. And he found what was true of sodium was true of all other bodies. What a world of facts was opened out to Kirchhoff now! The nature of these black Fraunhofer's bands was at once no further mystery. They were produced by the vapour of bodies in the sun's atmosphere absorbing that part of the light of the sun that these bodies were capable of producing. The bright lines produced by iron have corresponding dark lines in the solar spectrum. The explanation is clear, and we are bound to accept it, that iron exists in the sun's atmosphere. And, still further, the spectroscopy solved the question at once, whether the black spots on the sun were produced by a cooling absorbing atmosphere pouring down on the photosphere; or whether they were formed, as French physicists taught, by actual breaks in the photosphere itself. Again, recent investigation has shown the sun to be surrounded by a surging sea of incandescent hydrogen some 5,000 miles high, called by Lockyer "the chromosphere," with oftentimes a lower stratum of incandescent sodium and magnesium vapours, this true atmosphere being often disturbed by powerful convection currents producing enormous prominences, at times 27,000 miles high. And modern science has even calculated the rapidity of these movements. And yet further, by the appearances of certain bright lines, as, e.g., the assuming arrow-headed shapes and so on, they are able to determine the atmospheric pressures in the chromosphere and its prominences, and to prove that the pressure of the sun's atmosphere is far below that of the earth's.

But I must pursue this subject no further. These are extraordinary discoveries. But you will note they are a long chain of discoveries. And do you not think there are spirits in the spirit world joying as they listen to this story of the work of progress; but joying especially to think one or more of the links in this chain of discoveries were links forged by themselves?

In this work we are called upon now to take our part. It may not be unprofitable reviewing the history of science

and learning experience from the past, that we should ask ourselves, What have been the principal hindrances to development, and what have been the chief causes of its successes?

Amongst many obstacles in the way of progress I have only time to note *two*.

And, first, an undue respect for the opinions of great men, in vulgar parlance, a love one person has for pinning his faith to that of another. Do not misunderstand me. Men are not equally gifted. There is an intellectual as well as a physical superiority. That I grant; but the world is disposed to reverence and accept without due caution the opinion of a learned aristocrat. It seems to place such men on a throne above all others, and to regard it as little less than heresy to question a word they utter. Men argue thus: "See what they have done for science. Do you dare to criticise what *they* say? Do you venture to ask them the foundations of their assertions, or the details of their experiments as though you questioned their veracity?" Just as though intellectual force had a special law for itself, that it alone could suffer no decay. Let another carefully examine a mass of facts; let him with industrious activity leave no stone unturned to arrive at truth: but no matter; if only his conclusions are contrary to the merest speculations of one who is accepted as an authority, all his patient investigations will go for nothing, and he will be laughed at for his pains. This has been a terrible hindrance to development. Devotion to independent inquiry is, you may depend upon it, the only road to truth. To love truth for its own sake is the only way to get truth. Still I would say every opinion given by one who has shown himself an accomplished scholar, a persevering student, and an ardent philosopher, deserves very especial attention. We are not to dismiss his opinion offhand; but what I mean is, that we are not to accept his opinions on his mere assertion of their accuracy, unless he furnishes us with satisfactory experiments and well-digested reasons; so that, apart from him, we may form entirely independent opinions. In medicine and chemistry we are but too familiar with men who set themselves up as authorities, and we know too well what a bore they are. Trading on past efforts and discoveries, they look with an eye of miserable suspicion on one who dares question any theory they choose to propose, however far-fetched and sensational it may be. They seem to expect men to accept their opinions offhand, and not ask the why or the wherefore. And, unfortunately, the disciples of such men are numerous, for it is natural for men to like to lean on others—it is far less trouble—they like others to think for them; but it is a liking fatal to true and rapid development.

And this naturally suggests a second hindrance I would note.

A love some men have for theorising, and, as is generally the case, theorising on very insufficient data, and then often conclude by building a system on a few miserable experiments. I know of no greater curse to science than system-makers and system-mongers. They are, as a rule, only observers of nature so far as they can catch a single idea to support their pet theory. They care nothing for facts, unless they can manage by some process of conjuring to twist and turn them so as to suit their own peculiar views. If they fail in doing this they quietly set them aside. Thus you may account for the absurdities of a miserable system like homeopathy, against which there can be no need, I should hope, to warn you. Deeply do we deplore the fact that some brought up to love truth and to love freedom (for truth is freedom) have turned aside from paths of pure orthodoxy to hug the chains of error and falsehood. One fool may do such a world of mischief in a week that it will take the life of a wise man to correct it. Nay, more—many wise men may be required to undo the work of one fool. It is true, systems of this kind are of mere butterfly existence, fluttering about for a time, passing through an ephemeral life, and, sinking down at length into chrysalis quietude, give place to something new, and, because new, seemingly more charming. How men love

novelty! They can breathe no other atmosphere than change!

The remedy for all this is plain. Let us be content to be observers of nature, and let the record of our observations be not only circumstantive but faithful; by that I mean all we did observe, and nothing more. Not to start with a theory and hunt out facts to support it; but to hunt out facts and then build a theory, at the same time observing great caution about drawing conclusions. This is the sure remedy. Without any intention of falsifying our record we may do so unperceived by ourselves, owing to an admixture of the views and language of an erroneous theory with that of simple fact. Ideas are not facts, though men often think they *are*. Conjectures will not take the place of careful observations, though men often think they *do*.

There are many circumstances that have of late years tended very materially to assist this work of medical progress. A considerable impulse has been imparted to the progress of development by the recognition of the mutual relationship subsisting between the different sciences, whereby the phenomena and known laws of the one may be applied to the determination and elucidation of the general characteristics of the other. The causes of the manifestations peculiar to each branch of scientific investigation were for long limited to the special subject in which they were engendered, but as future research was brought to bear upon them they were found to be connected by laws common to all. And thus it has not unfrequently happened that the researches made on a more remote subject have thrown a light on one that has long resisted our attempts at explanation—so long as we studied it apart from other branches of investigation. Then, further, it is right and proper that we should acknowledge the deep debt of gratitude we owe the Medical Press, and I must especially mention the *Lancet* as being the first of our medical papers that ventured, amid the strongest protestations, to print the lectures of great teachers, thus scattering far and wide new and more extensive views of the various branches of the profession. Indeed, I would say one of the main aids to development is the facility of a ready and unrestricted communication of thoughts and interchange of ideas. But on these, as on various other points, I have no time to speak now.

I would merely note two principal means, by attention to which, so far as we are concerned, we may be enabled hereafter to take our part in this great work—the development of scientific research.

1. And the first is—the necessity for accurately mastering the foundations of medical science. It is a bad crop that has no depth of earth. There was considerable wisdom in directing that your first winter session, and the principal part of your second, should be devoted to anatomy, chemistry, and physiology; for these are the building's foundation. Let the various theories of surgery and medicine shift as they please, alter as they will alter in altering times,—if the foundation is thoroughly secure, then it is able to bear its tiresome burden. The facts of anatomy and chemistry, too, are facts in a great measure located in a region of certainty, and are out of the world of change. Surgeons may differ as to the treatment of aneurisms, but that will not change the normal position of arteries. Here, at any rate, is something like strength for you. Never think, then, time wasted that you spend in the dissecting room, or listening in this theatre to the humorous, laconic, yet learned addresses of him whom we count a worthy successor of the most popular of anatomical teachers. And, further, medicine could never have reached the high position it now occupies, nor will it ascend one single step in the ladder of development, unless it takes advantage of chemical research. I am claiming a high position for chemistry. I deeply regret that there are not the same inducements for the medical student to study chemical phenomena that there are for him to study anatomy, the authorities at Lincoln's Inn seemingly regarding it as quite sufficient that he should have attended a course of lectures. I believe medicine has been far too often divorced from

chemistry, and the divorce is fatal to development. Is it supposing too much, when I say that I do not think the day far distant when an analytical chemist will be an essential part of the working staff of every large hospital, and that the results of his examination of morbid specimens will suggest remedies far surer, far more certain than any we at present possess? Then, again, chemistry and physiology are twin brothers—closer born than Siamese Twins. On this I will venture to quote the words of one who is, of all men I know, best able to speak on this subject: "Chemistry," he said, "can have no knowledge whatever of the physiological operations of the human body, without a knowledge of physiology; and, on the other hand, physiology can have no competent knowledge of the actions taking place within that body, except through the aid of chemistry." These were Dr. Letheby's words, spoken in this Theatre last July.

Then, note again in what an unsatisfactory state at the present time is our knowledge of therapeutics. It seems to me the only correct method of learning the action of a drug is by carefully noting its behaviour with various reagents in the test glass. Thus, the physiologist, the pathologist, and the physician, begin to acknowledge that the only safe entrance gate to the true understanding of the action of the body in health, the cause and nature of disease, and, above all, the influence of medicines upon disease, is the laboratory of the chemist,—there to imitate, as far as may be possible in the test-glass and the crucible, the work going on in that hidden laboratory, where, without a moment's cessation, the great Worker is working perpetual change. Some of the strange processes of that secret laboratory have of late, in a measure, been laid bare to us,—not in their fulness I will admit, but sufficient to convince us that the operations of life are brought about by the action of forces with which we are tolerably familiar.

2. And now, gentlemen, finding that discovery has been a grand system of development, (as all great systems are, be they religious, political, or scientific,) it is clear that it now becomes our turn to extend and develop this chain of medical progress; to work from that point where others have been called upon to leave it. This is the work set us to do; nay, more, it is the work we set ourselves to do. But do not forget it is a *work*; and a work, moreover, that calls for indefatigable industry, untiring perseverance, and consummate patience. The first dawn of a great discovery may be the work of chance. Its details never are. We ask but one thing of those who join us to-day, and that one thing is *work*;—not to make resolutions for work on possible contingencies (such resolutions are worthless), but to work under any circumstances, "Act in the living present." And, further, we do not merely ask you to work now, but your profession claims as her right your devoted work for the remainder of your days,—not merely to "get up" what is already known,—for in that case what value will your life have been when you are dead and gone,—but to find out something that is not known, to leave some marks that may sustain your individuality, and hand down to posterity a little more than you received—a contribution, the result of your own work—to try and forge a few links in the grand chain of progress. Do you suppose for one moment that discovery is limited to a small handful that the world pleases to call "men of genius?" I am afraid you will suspect me of more enthusiasm than becomes the sober office of a teacher. I do not say that the best directed labour can ever supply what nature has refused; still it remains an experiment, uniformly sanctioned by time, that without unwearied toil, obstinate perseverance, and submissive resignation, neither the theory or the practice of any art or science can be fully acquired, and that, without them, genius is a bubble, and talent a trifle. Or do you think I am setting before you a somewhat too exalted view of our Profession? I hope none will say it is too exalted a view. You cannot aim too high, it is easy enough to aim too low. Believe me, an object of lofty pursuit, even if it be one of quite impossible attainment, is not, altogether, unworthy the ambition of

the truly scientific man, or, at any rate, it is better to aim at what is out of your reach, than be always supposing everything *is* out of your reach. Though you may not be able to scale the summit of the volcanic cone, you may yet reach its heaving flanks, and though you cannot decompose its loftiest fires, you may yet study the lava they have melted and the products they have sublimed. Because you fail in doing all you wish, it is poor philosophy that says, Do nothing at all.

I would not have you for one moment think that I am undervaluing the practical work of our Profession,—the cure of disease, the greatest of all human work. To make the lame to walk, the blind to see, the deaf to hear, and the dumb to speak. That is a noble work indeed! It is divine! Godlike! To sit in the dead of the night at the bedside of one who seems to be yielding up her life in a last long breath, at the very moment she is giving a life—a breath to another—to sit there, I say, and guard and fan that flickering life of a precious mother until it again burn brightly—it is a noble work! To restore to a distressed family, through the means the Almighty has placed in our grasp, one who has been its bread-winner for many a long year, and whose very existence may seem at this very moment to be more valuable than ever it was before—it is a noble work! To bring back to health, and, by a seasonable word of advice, to a life of peace and chastity, one bowed down with wretched shame, carrying on his very countenance dread records of his guilty folly, records that are constantly, painfully reminding him of lost purity and the price he has paid for his sin—it is a noble work! To bid the destroying angel flee from a neighbourhood by the cautious sanitary measures you may suggest, when it would seem as though his well-polished, keen-edged sword was lifted, and in another moment he would have struck—it is a noble work! To whisper a word of love and sympathy into the ears of one who is just ready to deliver up his spirit unto the God who gave it, a word that may lighten the dark, dark passage, that may shorten the long, long journey from which no traveller returns—it is, indeed, a noble work!

But our Profession is a jealous mistress; she will have no half service in this great work; she must have all your powers and energies, or she cares for none; she demands the purest enthusiasm. To bestow on other work a part, a fractional part, of your powers will be only to leaven that enthusiasm, and to divide those energies; and that must not be. Do you ask the reward of it all? Is it wealth? No. Is it rank? No; there are no coronets to bestow in our Profession. There will be none so long as

"Rank is but the guinea stamp."

Or is it renown you seek? Well, there are paths in our Profession for gaining that; but you must not seek it by a flowery road. A few sensationalisms will occasionally bring it, but sensationalisms are vipers that will bite you at last, and the bite is often deadly. Often the silent walls of the laboratory have been the unobtrusive and only witnesses of the arduous and patient researches of its occupant. Yet, think not that recompence depends necessarily from without. There is within man an arbiter awarding commendation, independent of the world's testimony. Many of those I now address may have felt the glow of satisfaction arising from the indomitable perseverance in a rightful, though perhaps difficult, course, at last carried to a successful issue. It is related of a mathematician that, on nearing the end of a most abstruse problem, upon the solution of which he had been engaged for many days, he became so excited and elated with the approaching certainty and correctness of his treatment, that he was unable to continue the subject, and had to depute another to finish what his own genius had suggested. Here nature for herself gave the testimony, and it was overpowering. Or do you suppose our Profession is one of *ease*? There you are terribly at fault; for it is a Profession, of all others, of ceaseless and responsible work. And that is the road to success. Nothing, as a rule, but the work of great men insured the success of great men. Work is a far surer

ladder to success than the patronising smiles of the aristocracy, or the kindly remarks of our merchant princes. I am afraid I shall be accused of preaching some dreary truths—truths little calculated to spur you on in the work you commence to-day. But there is this comforting reflection, that if work is the only road to success, at any rate it is the only pathway to happiness. Idleness is a failure in every respect; it has no one thing to recommend it; it is even bad policy. The drones of society are society's curse. They are eating bread which is not theirs, for they do not earn it; and it is no human law that decreed that if a man will not work he has no business to eat; and when such men die no one misses them, for they never did a thing to make one miss them. Nay, drowsiness is only another name for misery, because such men are painfully aware that their death will be no loss, and, as a rule, they are those who would wish, above all things, it were otherwise; but the price is beyond them—that price is work. It seems mysterious what they were created for. Time is a burden of lead to them; when it is day they wish it was night, and when it is night they wish it was day. Men around them soon learn their character and avoid them, for they can get nothing out of them, simply because there is nothing in them.

Then, further I would note, true happiness does not consist in taking in a stock of knowledge, but of perpetually giving it out as you take it in. We should all be not merely learners, but teachers. You cannot fulfil the great purposes of your being unless you are perpetually showering out from yourself whatever you possess. That is the true law of your existence, and all nature is the sermon on the text. Just look at the clouds soaring in their beauty in the field of heaven, bearing proudly in their pregnant bosom the full blessings of the rain, floating in such matchless grace, pleasing the eye with their many tints and varied charms. Is that, think you, the end of their creation? No; even they have a work to do. They are there to water the earth, to make it very plenteous, to cause its seeds to bring forth, to open rills and streams for man, to preserve life. And, unless development is to cease (which God forbid), your hands will have to do the work. Trading, as you will for a time on others' discoveries, do you not regard it as a work of common honesty so to arrange matters that others some day may trade on yours? To set before you science as a history of development has been my aim to-day. I have endeavoured to show you how a rapid succession of great discoveries have kept up the interest of the first impulse vigorous and undiminished. No funeral rites have ever been got ready for research, discovery, or development! And surely their grave need not be dug now. That is the lesson of the past. What an intense—what an everpresent sap and vitality we trace in this record of development! No ugly gaps have been permitted. No idle intervals to interfere between the most gigantic and dissimilar forms of inquiring energy. So glorious a past can promise nothing but a future as illustrious. The same powers, the same influences that have created men like Harvey, Hunter and Jenner are still at work—at work to-day, and will enable us to produce others whose works shall be as splendid and their names as durable as sublime!

And just gather up into a few words, the work, gentlemen, you are entering upon to-day:—to store your mind with whatever is already known for diagnosing the various forms of disease with which you may be brought into contact; to make yourselves conversant with all the changes those diseases may undergo, to be ready without loss of time to apply the best remedies modern science has suggested, for the cure or relief of the disease, and to propose such hygienic measures as may possibly prevent a repetition of the sickness. But, above all, to aim at being yourselves discoverers, each for himself aiding this great work of medical progress, each one ready when the call shall come, and come it will, to pay back again to the Just and Almighty Ruler the talent or the talents *lent* him, but only *lent* him, and ready, mark this—to pay them back with usury. This is your work—go, and do it.

Original Communications.

EXPERIENCES OF A REGIMENTAL SURGEON IN INDIA.

By C. A. GORDON, M.D., C.B.,
Deputy Inspector-General of Hospitals.

(Continued from page 244.)

HEAT APOPLEXY.

In what manner we are to account for the intense and peculiar heat of epigastrium and surface generally in this disease becomes a problem the solution of which is difficult. It deserves the fullest attention on the part of medical officers. In all probability, a direct connection will be found to exist between it and the deranged condition of the functions of circulation and respiration, which constitute an important part of the malady; thus, while during life the skin is so dry as to be utterly incapable of performing its functions as an emunctory, *post-mortem* examination reveals extensive pulmonary and cardiac congestion, the mass of blood at the same time indicating a state of imperfect decarbonisation. Doubtless, the insufficient *combustion* of carbon furnishes by itself an insufficient explanation of increased temperature, but all that I desire to indicate is, that a field for inquiry is here open.

Until a period comparatively recent, so uniformly fatal was this disease that it was considered as being absolutely beyond the power of treatment. Of late, however, as already observed, the results are more favourable, and we are now able to employ remedies with as much hope of success as in any other of the more important maladies which affect our soldiers in India. Having, some years ago, entered somewhat fully into the history of heat apoplexy,* it will suffice for my present purpose if I allude to the fact that, when the custom was to bleed freely from a vein, the patient being retained in the sitting posture, death occurred in all cases of the affection, the event often taking place while the patient was in the act of undergoing the depletion. How far this may have been connected with the treatment itself, it were needless now to discuss; but we cannot forget that, at the time referred to, not only were soldiers much more crowded together in their barrack-rooms than they now are, but so prevalent among them was the vice of spirit drinking, that we may fairly presume these powerful causes of the affection occasioned not only more severe attacks, but of a more virulent nature than are, as a rule, now met with. I believe that my present purpose will be served by the following cases, which illustrate the manner of treating the affection which recent experience indicates to be most generally successful, and which may, in brief, be said to include—1. Free affusion over the whole body, but more especially the head and epigastrium; 2. Free abstraction of blood from the temporal arteries; 3. Internal counter-irritation, as by the administration of croton oil; and 4. External counter-irritation, as by sudden vesication of the nape, sinapisms to the calves of the legs, &c.

Let us suppose, for example, that a patient was first seen when labouring under confirmed heat apoplexy, all the symptoms of which were complete; the manner of procedure was somewhat thus:—He was immediately brought on a bedstead outside the ward, and freely *soused* with water poured upon him from a height, and, if possible, by two persons at the same time; for a few minutes the shock was produced, as far as practicable, by directing the current upon his head and epigastrium, and if, as sometimes occurred, the unconscious man was capable of swallowing, cold water was put to his lips or into his mouth. He was next turned upon his face, and similar affusion applied along the spine, friction being by attendants made to his legs. If, in the meantime, he could be

* See *Edinburgh Medical Journal*, May, 1860.

induced to swallow several drops of croton oil, it was considered so much the better; but if not, some four or five upon powdered sugar were placed in the mouth while he lay upon his back, in the hope of some of it finding its way, as it often did, into the stomach, producing vomiting or free catharsis. One or both the temporal arteries were meantime opened and allowed to bleed, while the affusion and frictions were continued, it being found that no risk whatever existed of depletion being thus carried too far, inasmuch as the hæmorrhage ceased spontaneously, if not checked artificially. When, however, these remedies failed to produce effect, sinapisms were applied to the legs, and vesication on the nape produced by the application for an instant of a heated spatula.

These are energetic remedies, and they must be energetically employed. We no more can look for success in recovering a soldier rendered unconscious by an attack of heat apoplexy by the employment of such means applied for a short time and in an undecided manner, than we can expect to restore animation in a person asphyxiated by immersion in water by mild remedies. If, therefore, a medical officer be too apathetic or indifferent to fairly grapple with this disease, and leave his patient to the care of imperfectly instructed attendants, or to the languid attentions of native Asiatics, it is right that such a man should know that the soldier thus affected with heat apoplexy, and thus left, will to a certainty die. I have seen instances of the apathy and indifference to which I allude, not only in the treatment of this disease, but in that of others of fearful virulence. I have seen, as a matter of course, the results to be expected from such indifference, and it is because I have witnessed them that I now express myself as I do.

The case given below was the first I had the satisfaction of treating successfully:—

Private Jeremiah McCarthy, aged thirty years, admitted at Wuzeerabad, in the Punjab, 7th October, 1852, suffering from giddiness in the head and general debility. Had been subject a few days previously to diarrhœa. On the forenoon of the following day, he was found lying in the rear in a state of insensibility, and with all the symptoms of apoplexy of the hot winds; there was much suffusion of the eyes and the countenance; the temporal arteries were distended; the epigastrium was very pungently hot, and he kept constantly striking that region with his hand during his insensibility; he was voiding feces involuntarily in bed. He remained in this state for a period of upwards of two hours before treatment was employed; the remedial measures had recourse to were opening the right temporal artery; cold affusion to the head and epigastric region; slight cautery to the nape. It having been observed, during the state of unconsciousness, that he indicated a desire to drink, cold water was given, and he imbibed it with avidity. After he had bled to probably twelve ounces, consciousness began to return. He then had a dose of croton oil and calomel, and in the course of a few minutes afterwards he was able to answer questions rationally; complaining, however, of a sensation of weight and giddiness in the head. The following is an extract of his case from the medical register:—

October 10th.—Considerably better this morning; pulse moderate; skin cool; respiration natural; slept well during the night. R Hyd. chlor., gr. ij.; pulv. ant. co., gr. ij., ter in die.

11th.—Pulse moderate; tongue furred; doing well, but is weak. R Acid. sulph. dil., ℥x.; inf. chirette, ʒj., ter in die.

12th.—Pulse moderate; tongue furred; complains considerably of pain and swelling of the epigastrium. Cont. med., et app. emp. vesicat. epigastrium.

13th.—The pain of epigastrium considerably less; tongue less furred; pulse still weak. Cont. med., ter in die.

14th.—Tongue cleaner and moister; pulse stronger; does not complain of any epigastric pain. Cont. med., ter in die.

15th.—The same remark applies.

16th.—Is now perfectly free from epigastric pain; gums swollen; breath very fetid (mercurial).

The recovery of this man was so far complete that he was subsequently sent to England as an invalid, and discharged the service; but so unexpected at the time of his illness was any other result than death in the case of a person attacked as he was, that, when I had seen him, the rites usually performed over the dying by priests of the denomination to which he belonged had been administered; and I was so unfortunate as to incur much ill-feeling because I had been the means of restoring a man who should, it seems, according to all "spiritual" rules, have "gone, we know not where."

The following cases occurred during the mutiny—namely:—

Johnston, 10th Foot, forty years of age, sixteen in India; a hard drinker, although he had enjoyed good health. On the 6th of May, 1858, he was, in all respects, in apparent good health. On the 7th, the field force employed near Arrah marched at daylight, and continued to do so till about ten a.m., he accompanying it. About eight o'clock he was observed to stagger in the ranks, and in other respects his manner was so strange that his captain, mistaking the cause, ordered him into arrest. The morning was extremely hot and oppressive, and, as our route was westward, the direct rays of the sun fell upon the backs of all. He having been ordered to the rear, he doubtless intended to wait till that part of the regiment should come to him. He did so, and was found by the guard lying by the roadside, in a partially unconscious condition; he was nearly pulseless; the breathing was hurried and gasping; the temperature of the surface was natural; there was no distension of the temporal arteries; the face was somewhat pallid; pupils contracted. Affusion was applied to the head, and had the effect, for a minute or so, of rousing him to consciousness. He fell back to his former condition, however; in about half an hour from this time his face and surface had become livid; he moaned heavily, but without stertor; and almost instantaneously died.

His case may be considered as an example of the manner in which death by this disease occurs, after direct exposure to solar influence, in the person of a man who had been for years an habitual drinker of ardent spirits.

Maher, 10th Foot, twenty years of age, seven months in India; not of very full habits; admitted into hospital on 24th May, 1858, while on service against the Sepoys in Jugdespore jungles. In the forenoon of that day marched with a portion of the regiment against the enemy, but at three p.m. was brought back to camp apoplectic, he having suddenly fallen down in the ranks an hour previous, with the well-known symptoms of heat apoplexy. On being brought to hospital, unconsciousness was complete; the surface of the body was less hot than is usually the case during attacks of the disease; the hands were firmly clenched, the thumb of the left being drawn across the palm, that of the right was semi-flexed; the conjunctivæ were much suffused; the eyes slightly turned upwards; pupils contracted and insensible; he moaned heavily; breathing was heavy, and at times stertorous; much froth issued from the mouth; the pulse was variable, at one time scarcely perceptible, at another wavy, but not rapid; the face and general surface were congested and bloated.

Affusion was immediately employed to the head and epigastrium. The right temporal artery was opened, and allowed to bleed, the patient being in the recumbent position while affusion was continued. Five grains of calomel and five drops of croton oil were placed upon the tongue, and on applying a jug of water to the lips he swallowed a few mouthfuls. Shortly afterwards he vomited freely a quantity of green bile and mucus; the pulse assumed a more regular rhythm; the bleeding from the artery ceased spontaneously, and he appeared slightly conscious. The affusion was now repeated, as also the dose of calomel and

croton oil, and an enema of turpentine administered. About five p.m. vesication on the nape was instantaneously produced by the application of a hot spatula; he was kept cool, and about seven o'clock fell asleep. At eight p.m. he was found conscious; skin not very hot; bowels had been profusely moved; pulse natural; and the expression of the face so much improved that he did not look like the same person who had, a few hours before, been brought to hospital. His recovery was rapid and complete.

I have given one fatal case, my object being to indicate the usual course of this very alarming disease. Many such must occur under any method of treatment, and especially when, as in that given, the subject of the attack had been for years of intemperate habits. I believe, however, that by following the plan of treatment I have indicated, a satisfactory degree of success will be obtained. Such was the case in my hands, and in those of other medical officers who adopted it; but, as I said before, so I repeat, neither it nor any other plan will be successful if guided by apathy, indifference, or indecision.

(To be continued.)

SCOTLAND.

CHAIR OF PATHOLOGY.

On Friday last the Curators of the Edinburgh University, by a majority of four to three, elected Dr. William Rutherford Sanders to the Chair of Pathology, vacant by the resignation of Dr. William Henderson.

By this election the Curators have ratified the opinion almost universally held by the Profession, and which we have consistently maintained; and Dr. Sanders reaps the reward of a continuous and persevering devotion to science and truth, not for their temporal rewards, as too many do, but for the sake of truth alone. In our profession it is very rare that a devotion to science, so pure and single-hearted, obtains such a public acknowledgment, and we therefore think that the Profession itself is to be congratulated even more than Dr. Sanders himself, by whom the position attained was chiefly desired, for the sake of a wider field of usefulness in his own favourite department. For the unsuccessful candidates, and especially for Dr. Stewart, who was "a foeman worthy of our steel," we condole with them on their disappointment, we congratulate them on being beaten by a competitor in every way so worthy, and we hope that a long career of devotion to science and a future of true fame may yet be theirs.

EXAMINERSHIP AT ABERDEEN.

We understand Dr. C. Meymott Tidy is a candidate for one of the vacant Examinerships at the University. He is, as our readers know, Joint Lecturer on Chemistry at the London Hospital. Dr. Tidy graduated at Aberdeen in 1866, with highest honours, as Bachelor of Medicine and Master in Surgery. The University, in electing him, would strengthen its hold in the metropolis; and the Introductory Lecture at the London Hospital, which he gave last Friday, is a great proof of his powers, while the fact that it had to be delivered in the Chapel shows the popularity he has already achieved.

CONSTRUCTION OF THE NEW ROYAL INFIRMARY.

PROFESSOR Sir James Y. Simpson has addressed a most important letter to the *Scotsman* on this subject. The following paragraphs will interest all our readers:—

1. That in the past history of medicine numerous chemical emanations and vapours have from time to time been

brought forward and temporarily lauded, under the idea that by their disinfectant, antiseptic, or air-purifying powers, they would render the air of wards of hospitals, &c., more healthy; but none of them have stood for any length of time the test of experience. In the end of the last century an Edinburgh graduate got a Parliamentary grant of thousands of pounds for the discovery of one which is now never used.

2. That, several years ago, Dr. Lemaire, of Paris, as well as Declat, Kuchenmeister, Bottini, and others first in their writings advocated the use of carbolic acid in medicine and surgery, on the ground of its being a destroyer of low germ life, and that Dr. Lemaire more especially proposed its use in hospitals as calculated, among other things, to prevent pyæmia—one of the most common causes of death among surgical patients. (See Lemaire's Book on Carbolic Acid, 1863, and 2nd edition, 1865, p. 364; Declat's work on *ibid.*, p. 24, &c.)

3. That in the great hospital of the Hôtel Dieu, of Paris, M. Maissonneuve, one of the most distinguished of living French surgeons, used, from 1861 onwards for a succession of years, carbolic acid in dressing the wounds, &c., of his patients, though he has now abandoned it for, I believe, alcoholic and other applications. But I am not aware that it was observed to diminish in any degree the prevalence of pyæmia among his patients.

4. That, since Professor Lister adopted and wrote on the use of carbolic acid in 1867, it has been employed extensively in most of the surgical wards of the Royal Infirmary of Edinburgh. During the eight years from 1859 to 1866 inclusive, before the introduction of carbolic acid here, the death-rates (chiefly from pyæmia) among the limb amputations amounted to 40 per cent. During the two years 1867 and 1868 this dreadful mortality rose to 53 per cent. (See the official returns in the *Edinburgh Journal of Medicine* for June, 1869, p. 1106.) This increased death-rate was not, I believe, directly owing to the introduction and free use of carbolic acid in the wards during these last years, for such death-rates are liable to intermittent changes from time to time; but, at all events, the increased mortality took place in despite of the employment of the specific safeguard which Mr. Syme now suggests as fitted to modify the opinions of our architects in the construction of the new hospital.

5. That if Mr. Syme really believes his proposition to be true—namely, that the new Infirmary might be safely built as a block or blocks of several storeys in height, because the air of its wards could always be kept pure by a chemical nostrum or effluvium—then assuredly it was utterly unnecessary for him to have pleaded, as he has so ably done, for the removal of the institution from its old, and restricted to its new and more spacious site; inasmuch as there was, as every citizen knows, plenty of room in the former locality for one or two great and tall-mansioned hospitals of several hundred beds each; and much money and much disputation might consequently have been spared to the community.

6. That in all our palatial British hospitals with 400 beds or more the mortality in limb amputations is, on an average, as high as 40 in every 100, while in all the British hospitals of 100 beds or less, the data of which were a few years ago collected officially for a report to the medical officer of the Privy Council, the mortality is as low as 17 in the 100, making the enormous difference of 230 lives in every 1000 human beings operated upon—a startling fact, which, with many others, shows that there is in the construction of hospitals always imminent peril in the aggregation of the patients, and safety only in their segregation.

7. That, in the construction of our new Infirmary, the great disinfectants and antiseptics that we should alone depend upon are abundance of space, abundance of light, and, above all, abundance of fresh, pure, and ever-changing air to every patient in every ward in the hospital—a result that will probably be attained most cheaply and certainly by leaving the present Watson's Hospital, with its numerous class-rooms, bed-rooms, &c., for the administrative part of the institution, and erecting upon the ground above and below this central building a series of village or villa hospitals or wards, furnished with all the latest and best sanitary improvements.

I am, &c.,

J. Y. SIMPSON.

APOTHECARIES' HALL, LONDON.—At the preliminary examination in arts, held at the Hall at the end of September, 114 candidates presented themselves, of whom 41 were rejected and 73 passed, who received certificates of proficiency in general education.

VACCINO-PHOBIA.

No. III.

WHILE we have deemed it our duty to expose the ignorance and prejudice of the vaccino-phobias, we are ready to offer them such assurances as their state of mind may need, and to make excuses for all the honest fears they may feel. Mothers who hear heartrending tales of the sufferings of tender infants are not to be condemned for natural anxiety; it is only foolish agitators, who go about repeating their “raw-head-and-bloody-bones” alarms, who excite indignation. Such persons deserve to be treated with that absolute neglect which would be to them, perhaps, anguish. We would not please them by the slightest notice, did not others suffer from their folly. In the interests of the fearful alone we continue our observations on this well-worn topic. They may be glad to learn that all their reasonable fears may be allayed, that they may avoid the possibility of inoculating other diseases with the cow-pox, and yet preserve their children from the more dreadful small-pox. Dr. Blanc's paper at the Exeter meeting of the British Association for the Advancement of Science, which has already appeared, in abstract, in our columns, has been published as a pamphlet,* and sets forth a remedy for the alleged evils of vaccination, of which all who are fearful may easily avail themselves. To our notion he admits these evils to be greater than they really are, and we are far from subscribing to many of the statements he makes in his laudable desire to extend his remedy, which consists in a return to the plan of employing lymph direct from the heifer, instead of that which has passed through the human body. This plan is undoubtedly effective; it is extensively employed in other countries; it has the approbation of such authorities as Lemoix, Depaul, and Warlomont; our own countrymen Ceely, Ballard, Marson, and others endorse it; Dr. Blanc has introduced it into London with great success; finally,

it is a return to the first practice of Jenner, by which the value of vaccination was first demonstrated. Cow-pox is a disease of the bovine race, and in that race never changes—never gives rise to anything else. Lymph taken direct from the heifer will then be pure. There can be no question, in such a case, of contamination with syphilis, since that is a disease of which the animals are not susceptible. Calves are not liable to any diathetic diseases at all, and, therefore, while we eat the flesh and drink the milk of the bovine race, we need not fear inoculation direct from them. Dr. Blanc has organized an establishment in London for the supply of lymph from young heifers, and we would certainly urge all who have any doubts on the matter, or experience any want of lymph, to adopt his recommendation. Dr. Blanc says, and we quite agree with him, that “we should, at least, allow those who object to vaccination through fear of contagion to choose between humanized lymph and spontaneous cow-pox, transmitted in all its purity from heifer to heifer.” Happily, we do allow the choice—always have—and the most enthusiastic supporters of a compulsory law have never wished otherwise. Dr. Blanc has now, for the first time, practically permitted the choice by making the latter mode available, and deserves the thanks of all. He is, however, we fear, over sanguine when he writes that “anti-vaccinators, unless deeply prejudiced and unwilling to listen to reason, will be the first to join the ranks of the true friends of vaccination, and by their good example to carry conviction even to the most stubborn adversary to this great blessing.” Unfortunately, anti-vaccinators are “deeply prejudiced and unwilling to listen to reason.” They take up a spirit of opposition, distort facts to propagate that spirit, and embody the whole of their feelings in the one prefix “anti.” It is to preserve the sensible part of the community from the dangers to which this insignificant minority of “anti-vaccinators” exposes it that a compulsory law has been enacted. Sensible people had long before availed themselves of the benefits of Jenner's discovery. Having said thus much we may record our entire disagreement with Dr. Blanc's deductions from the statistics he quotes in reference to an alleged increase in the number of cases of small-pox after vaccination. Jenner said that a person who had had cow-pox was “for ever after secure from the infection of small-pox.” If he meant this literally we know he was mistaken; and subsequent experience does not show that the protection is less, but only that in the larger number of cases, exceptional ones become also more numerous.

When we say, as we said in a former article, that vaccination is a complete protection against small-pox, we imply no more than when we assert that this last disease affects an individual but once in his life. Medical men know well enough, and many of the public know too, that any of the eruptive fevers may occasionally recur in the same person; although the fact that they occur but once is often included in the definition of them. Why should we expect vaccination to be more perfect? For practical use to the community it affords complete protection; it saves tens of thousands of lives yearly; it saves hundreds of thousands of disfigured faces, of sightless eyes, and other sad afflictions; the alleged evils attendant upon it are utterly unproved, many of them merely imaginary; the occasional inconveniences entailed are not worth a thought in comparison with the blessings

* Compulsory Vaccination. By Henry Blanc, M.D., F.R.G.S., &c. London: J. Churchill & Sons.

it confers; if all the evils that have been imputed to it by trustworthy men were proven, it would still be worth while to practise it, for immunity from small-pox would be cheaply purchased at such a cost. How much more, then, when with such care as the profession generally exercises, reducing the chances of any imaginary evil to a minimum, should the public be warned against the sophism and fanaticism that has caused the recent spread of vaccino-phobia!

Notes on Current Topics.

The Baddesley Endor Murder.

At the last Warwickshire Assizes, Michael Adkins, aged twenty-two years, a miner, was tried before Mr. Justice Hayes for the wilful murder of his wife, Harriet Adkins, at Baddesley Endor, near Atherstone. It was a double murder, for the poor victim was on the eve of becoming a mother. It seems that the murderer shot his wife, and that he subsequently accounted for the catastrophe by stating that the deceased shot herself, but varied his version of the subject by saying that the gun went accidentally off whilst he was examining it. It appeared that they lived unhappily together. The jury found the prisoner guilty, and he was accordingly sentenced to death. A petition praying for a commutation of the sentence was got up, and on the eve of execution the prisoner was respited during Her Majesty's pleasure. But the most important part—a step scarcely to be conceived, irreconcilable with the facts of the case, the murder of the woman and the mature child *in utero* within a brief period of entering the world, is the receipt of a communication by the Governor of Warwick Gaol from the Secretary of State, commuting the sentence to twelve months' imprisonment *from the date of the prisoner's conviction*. Surely this is some erroneous perversion of justice! It is something more than an illustration of the uncertainty which exists in the present anomalous mode of administering criminal law in capital cases. It would be an outrageous occurrence if influence brought to bear by a local member of Parliament could so affect the Secretary of State to deal out justice unjustly. Have the judge and jury who tried this case been privy to this hole-and-corner arrangement? Is society safe in having, nine months hence, thrust among them the murderer of his wife and his unborn child? If a man steals a loaf to appease the pangs of a starving family, the punishment is little short of that which a clement Secretary of State, in the tenderness of his heart, considers sufficient for the most revolting crime, unsurpassable in its cruelty, that man can be guilty of! This subject affects society, and we call for an explanation, if it be possible for an explanation to be given.

Transfixion of the Heart without Death.

A RARE, if not absolutely unique, pathological fact has been communicated to the Institute of Sciences of Milan, by Dr. Biffi. He showed the heart of Count Philippe Mancini, a lunatic, who, in an attack of frenzy, killed his father, and who had made several attempts at suicide, dying finally in a successful effort. The autopsy shows a needle implanted in the heart, so that four and a-half

centimetres of it extended into the left ventricle, and the point perforating the mitral valve passed for one centimetre and a-half into the corresponding auricle.

Inquiry resulted in it being discovered that the lunatic had declared that he had introduced the needle into his heart twenty-two minutes before his death; but, having presented no morbid symptom or functional derangement either of his chest or heart, or even of his pulse, this avowal was taken for one of his numerous fantastic stories.

Practical v. Theoretical Surgery.

THE flippantly-juvenile school of surgeons, with whom it has been the fashion to sneer at the sterling practical rule-of-thumb surgery of their fathers, have received a stinging rebuff from no less an authority than M. Nélaton, and are thereupon very irate. The editor of *Figaro* had requested M. Nélaton to give public expression to his opinion on the merits and demerits of medical education of the period. He writes in reply:—

"You ask me my opinion on surgical study in France at the present moment. Here it is: I am glad to see the rising generation renouncing the false semblance of exact and profound science, which has resulted almost exclusively from microscopic researches, in order to apply themselves anew to surgery based on the great indications furnished by clinical observation.

"It is in the inculcation of these principles that the great masters of the present century, and especially Dupuytren, the most glorious of them all, have given to the French school the real renown which it yet enjoys in the universal world."

It is quite obvious that, in this forcible enunciation, M. Nélaton has not in the least committed himself to any depreciation of microscopic or physiological research. He has merely asserted the fact that it must be always secondary to practical surgery, and that raw and conceited "professionists" are not to assume a character which they have not acquired by the observation of disease or the performance of work. The reaction has happily at last set in against the German pseudo-theoretic quackery, which has enveloped modern medicine in superfluous and incomprehensible verbiage; and it is permitted to us now to hope that fingers, eyes, and brains may have a chance against long tongues and illimitable self-sufficiency.

Mr. F. W. Newman's Idea of the Profession.

WE alluded some time ago to Mr. F. W. Newman's encouragement of the opposition to vaccination. We are sorry to see that this gentleman, enraged by the vexatious prosecutions that have lately annoyed many of the best friends of vaccination, has been induced to write another letter to the periodical of the anti-vaccinators.

Under the pretence of reviewing a pamphlet, parts of which we as strongly condemn as he could, but other parts of which he would have done well to digest, Mr. Newman launches out into a venomous tirade against the Profession, and raves about "insidious medical tyranny," which he declares is as "conceited and fatuous as it is immoral." Unmindful, however, of the question he has taken up, he rushes off to a totally different one—the Contagious Diseases Act, and the proposal to extend it to the civil population, and angrily accuses all doctors of desiring this in their own interest. Such logic may be

well suited to the comprehension of anti-vaccinators, but it is as unworthy of Mr. Newman as his imputation of evil motives to the whole Profession is unworthy of any gentleman. We do not propose to follow him through the wholesale abuse he heaps upon us. The public know well enough that the Profession is disinterested, and as for Mr. Newman declaring that medical men encourage vice, it only shows into what a womanish rage he has worked himself. Still, we may be calm enough to set him right once for all. The Profession has never supported the notion of extending the Contagious Diseases Act to the whole population. Some medical men support the proposal, and they have as much right as Mr. Newman to hold their opinions; but they no more represent the Profession than Mr. F. W. Newman does the Church. The present writer dislikes the idea quite as much as Mr. Newman does, but he is not blind to the injustice of therefore accusing the Profession of wishing "to make vice comfortable." Of all the tissues of misrepresentation it has been our lot to read, this last performance of Mr. Newman's is most astounding, though he says he has "carefully considered every epithet" he applies to the faculty, "which," he exclaims, "must not be allowed to take us by the throat and stab us with a poisoned lancet." His idea of the medical faculty could not have been gained at University College when he held the Chair of Latin at that institution.

The Perils of Petroleum.

But a little while ago the danger to which passengers may be exposed while travelling in company with petroleum was too widely illustrated on the Irish Channel. Last week a more terrible conflagration took place in the magnificent French port of Bordeaux, where sixteen vessels were burnt, in consequence of an explosion on board one petroleum-laden ship. The flaming barrels floated about after the explosion, carrying fire in all directions. This catastrophe finally suggests the thought that some strict regulations should be imposed on the removal of such dangerous substances from place to place. A similar calamity may occur any day in our own ports. A single accident, and death and destruction are dealt round in every direction. How are such occurrences to be prevented? Chemistry, it has been said, may yet enable us to render the transport of petroleum safe, but meantime we are in fearful peril. A severe restrictive law would be justifiable in the interests of the community.

The Effects of Transfusion of Blood.

THE Statistics of Transfusion of Blood, which have been published by Professor Iandors of the University of Greifswald, will be read with much interest.

Transfusion has been practised 99 times in cases of hemorrhage. Out of these eleven cases were so grave that no favourable result could be hoped for. In the 88 remaining in 65 the result was satisfactory, in 20 there was no success, and in 3 the result was doubtful. The operation had been performed in 12 cases of poisoning, in 3 of which the results were favourable, and in 8 the contrary.

The Medical Club.

A GENERAL meeting of the Club will be held at the Club-house, on the 13th inst., at 2 p.m., Sir William

Fergusson, Bart., in the chair, to elect the Committee for the ensuing year, and to take into consideration the following resolution and amendment:—

"That the Medical Club shall now cease to be a Proprietary Club, and that the resolution passed on the 8th Nov., 1866 (limiting the liability of the members to the amount of their entrance fee and subscription), shall now be rescinded, and an allotment made, in equal shares among the members, of the necessary capital to enable the committee at once to carry this resolution into effect."

"That it is not desirable to rescind the resolution passed on the 8th November, 1866, but that the Medical Club be conducted on the proprietary principle, the same as heretofore, in accordance with the agreement now existing between the Honorary Secretary and the Club."

The general result of the operations of the year, to be deduced from the financial statement, is that an income of £1,684 has been received from entrance fees and subscriptions, £1,209 from the sale of provisions and other sources, and £679 from sub-letting that portion of the house not in the occupation of the Club,—making, in all, the sum of £3,574.

The expenses (including additional furniture and household requisites) amount to £4,006, and, but for the balance of £796 4s. 5d. in hand at the commencement of the year, there would have been a deficiency of £431 16s. 3d.

It must be noted that included in the amount of subscriptions is the sum of £239 4s. 9d., paid by certain of the original members as a voluntary additional subscription, in lieu of the uniform increase proposed last year. The additional subscription was guaranteed for only two years; and if it had not been for this fund, the deficiency would have been increased to £671 1s. 0d.

The New Hypnotic.

THE statements of M. Librich as to the anæsthetic agency of chloral have been subjected to investigation by M. Demarquay, and the results have been far from confirming them. On only a few points are the two observers in accord, and notably on the rapidity and power of chloral as a hypnotic, and as an agent for obtaining muscular relaxation and also the prompt and complete recovery of animals, however far the action of the chloral might have been pushed. M. Demarquay sums up his conclusions as follows:—

1.—Chloral has a well marked hypnotic action especially on weakened and feeble persons.

2.—The duration of its action is in direct proportion to this weakness.

3.—The sleep which it produces is generally calm and is not agitated even in patients who are the subjects of severe pain. This result leads M. Demarquay to advise its use in diseases where sleep and muscular relaxation are required.

4.—The agent may be given in high doses, since no accident has been known to result even from 1 to 5 grammes doses.

The sleep produced is quite different from that obtained with chloroform. The least noise awakens the patient, but he falls asleep again immediately. The slightest puncture, or even a mere pressure, will elicit complaint; he immediately removes the limb that has been touched. Dr. Demarquay will not venture to say that there is over excitement of the skin, but he can affirm that, however deep the slumber, tegumentary sensitiveness remains entire. Chloral is, therefore, not applicable to surgical operations.

Cholera in the Punjab.

PAINFUL accounts of cholera have been coming in daily from Umritsur (in the Punjab), a city which seems to afford an illustration of the extreme to which Oriental uncleanness can go. A few figures will show the frightful ravages the epidemic has been making—amongst the native population, of course. On the 16th August, 118 deaths from cholera out of a total of 134; on the 17th, 110 out of 124; on the 18th, 119 out of 133; on the 19th, 102 out of 122; and on the 20th 97 out of 111. The following later intelligence has been received by telegram:—"Cholera returns—eighty-four on 22nd, ninety-eight on 23rd, and eighty-three on 24th. Deaths awfully sudden on Monday. All civil, executive, medical, and police officers ordered down from the hills." Up to the 16th August inclusive there had been, according to a contemporary, 833 deaths reported from cholera within eight days, an average of 104 a day. The inhabitants were leaving the town by hundreds, some say thousands; and as an aggravation of the evils of the district, cholera was beginning to show itself in the neighbouring kusbas and villages. It is feared the plague will extend. The Government of the Punjab had been roused to action by the impending famine crisis, and had issued instructions for the re-opening of famine works connected with the exterior town drainage. So far well, but those who know something of the place tell us that until all the frightful sources of disease within the town are filled up, all other works connected with the drainage of the place are next to be thrown away. There are said to be two enormous reservoirs of the filth of the neighbourhood.

The London Hospital.

AFTER the introductory address, which on account of the large number of auditors who could find no room in the anatomical theatre, was delivered in the chapel of the hospital, the biennial festival of the college was held at the London Tavern. Mr. Critchett presided at this dinner, and was supported by some of the old staff and many old students. The present professors were well represented.

This is the second time, as our readers will remember, that the Hospital Chapel has had to be used for the address at the London. The last occasion was when Mr. Critchett delivered the lecture. That was reported in full in our columns, and in the present issue will be found the lecture which was this year thus honoured.

The Stamping-out of Small-pox in Ireland.

THE modicum of truth which there may be in all the bluster of the vaccino-maniacs has certainly no reference to the protective influence of vaccination. It cannot be for an instant maintained, in the face of statistics, that vaccination has not proved perfectly successful in saving the public from the horrors of the small-pox epidemics of olden times. There has been no more forcible illustration of its efficacy than the effect of compulsory vaccination in Ireland. Small-pox no longer exists. It has been absolutely and totally extirpated, and if it be reintroduced it can never obtain a footing but by culpable negligence in enforcing the law. The Poor-law Commissioners have circulated a letter—we might call it a triumphal *paean*—on the subject, which they have issued

to Boards of Guardians under the heading, "Cessation of Small-pox." We reprint it:—

CESSATION OF SMALL-POX IN IRELAND.

SIR,—Adverting to their Circular Letter of the 23rd February last, on the subject of the diminution of small-pox in Ireland, as shown by the returns for the years 1867 and 1868, the Commissioners for administering the Laws for Relief of the Poor in Ireland request the attention of the Boards of Guardians of Unions to the quarterly returns of the Registrar-General for the two first quarters of the year 1869, from which, and from the absence of any report for several months past of any case of small-pox, the Commissioners infer with confidence that that disease is now no longer existing in the country.

The introduction of small-pox into Castlebar Union, by an inoculator at the close of the year 1868, was, as stated in the last annual report, followed by 67 cases of attack and four deaths in that Union. Two of these four deaths and one other death in Belfast Union are all the deaths from small-pox which were returned to the Registrar-General for the quarter ended on the 31st March last. Independently of Castlebar Union, there were only 7 cases of attack, none of them fatal, during the quarter ended 30th June last, viz., 4 in Ballymena Union, 1 in South Dublin Union, and 2 in Belfast Union. The returns of the Registrar-General for the quarter ended 30th June last contain no deaths from small-pox; and the Dispensary Medical Officers have reported no case of small-pox as having occurred since June last.

How far the present immunity of Ireland from this fatal scourge may be due to the working of the vaccination laws, and whether it may be due in some degree also to the improved sanitary condition of the people and the general absence of epidemic disease, is a question which may be left for solution to the further progress of events.

It is encouraging, however, to observe that the present total cessation of the disease in Ireland has been gradually approached since the compulsory vaccination of children has been put in force under the Act of 1863, the annual mortality by small-pox having been for many years previously about 1,000 deaths on the average, representing, of course, a very much larger number of cases of attack and disfigurement. The course of decrease in the mortality has been as follows: in 1864, the number of deaths was 854; in 1865, 347; in 1866, 187; in 1867, 20; in 1868, 19; in the first quarter of 1869, 3; and in the second quarter, none.

Whether or not small-pox still remains dormant in the country, and may be expected again to break out under less favourable circumstances, it is quite clear that every part of Ireland is at all times exposed to the introduction of the disease, either accidentally or by design, and therefore that the only security lies in a steady maintenance everywhere of the protective means afforded by vaccination.

By Order of the Commissioners,

B. BANKS, Chief Clerk.

Poor-law Commission Office, Dublin, 20th September, 1869.

The Opening of the London Medical Schools.

THE opening session has been duly celebrated by the usual introductory addresses. October the 1st, the opening day of Medical Schools and Colleges in London, has witnessed the annual inauguration at nearly all the Metropolitan Hospitals. One or two institutions postponed their opening to Monday, the 4th; and the Royal Hospital of the city—St. Bartholomew's—was obliged to give up the usual meeting, in consequence of the natural dis-

content of her old students at the injustice inflicted upon Dr. Mayo, and of which we spoke last week.

We make no attempt to supplement the abundance of advice that has been proffered. We are content, so far as space permits, to allow the eloquent lecturers to speak for themselves, and, with this object, devote a large portion of our columns to the reports. The masterly address of Dr. Meymott Tidy at the London Hospital we give in full. For others we have only space for brief abstracts.

How can we supply the place that ought to have been occupied by St. Bartholomew's? No response has been given to our appeal to the staff of that celebrated school, to separate themselves from the wrong doing of the lay-governors. We beg, then, to put on record that the Students held a meeting, on the 1st October, at the Albion Tavern. The following resolutions, passed unanimously, speak for themselves:—

"1. That this meeting desires to express its regret that the hospital staff have decided to omit the customary inaugural address and welcome to the new students, and that by this omission an unnecessary stigma has been cast upon the Medical School of St. Bartholomew's Hospital.

"2. That this meeting desires to express, also, its unqualified dissent from, and disapprobation of, the course of action taken by Mr. White and the House Committee in dismissing Dr. Mayo from office for complaining of the insufficiency of the junior staff, and the consequent maltreatment of the out-patients, and condemns the endeavour to silence, by such means, a straightforward and manly protest in a public cause. It wishes, also, to testify its hearty sympathy with, and to tender its best thanks to, Dr. Mayo, unsupported as he has been by any expression of opinion on the part of the Medical Council.

"3. That this meeting believes that the defects in the present administration of the endowments of St. Bartholomew's Hospital call for Parliamentary inquiry and permanent Government supervision in the interests of the public.

"4. That the present system of electing officers to the staff is not calculated to secure such clinical teachers as the pre-eminent opportunities of the hospital demand.

"5. That the best thanks of this meeting are due to the public press for the manner in which they are seconding the efforts now being made to further the cause of hospital reform."

Latest Intelligence with a Vengeance!

WE have often smiled at the frantic efforts of our elderly contemporary, the *Lancet*, to obtain the latest news. Its staff seem to fancy that the Profession care, above all things, for gossip and news. As this journal appears on Wednesday, and all the others on Saturday, our contemporaries have but a couple of days all to themselves; or, taking the Tuesday and Friday as printing days, the result is the same. The *Lancet* has been particularly desirous to keep up its position, and hopes to do this by the vigour of the news department.

It has, in its anxiety, at last entered into competition with the Atlantic cable, which gives our American cousins news of our doings several hours in advance. Only the *Lancet* has not the help of the sun, and so scorns the matter of difference in time.

Last Friday the London Schools were opened—mostly in the afternoon. The *Lancet*, containing abstracts of the lectures, was to be bought in the morning. We ourselves read them between 10 and 11 a.m., and then went to hear one at 4 p.m. Of course, this feat was accomplished by the aid of the lecturers, who did not expect their self-written abstracts to take the breath out of their own eloquence by their premature appearance. Still, country subscribers got them next morning, which, with a weekly

paper, would have been impossible in the ordinary course. Besides, that pestilent paper of Wednesday—the *MEDICAL PRESS AND CIRCULAR*—which is making such strides, had the wind taken out of its sails. 'Twas a very good stroke, and we commend the 'cuteness of it. Still, is news, apart from anything but lateness, the first requisite of a scientific journal? We shall continue our plan of taking account of the quality of the matter we select for our readers. A daily paper thus comments on the incident we have named:—

"A very amusing incident, although in some quarters it caused intense annoyance, occurred in connexion with the opening of the Medical Schools yesterday. It seems to have been the custom of the gentlemen delivering the inaugural addresses to give abstracts of their lectures in the medical journals a day or two before their delivery, so that authorized reports may be secured for the Profession. These reports have generally appeared in the number of the paper following the 1st of October, but yesterday one of the medical journals published the whole of the lectures, with one exception, before the first of them had been delivered. The gentleman who escaped anticipation was Dr. Johnson, of King's College, whose address came before his auditory with freshness; but in all the other cases professors and students were fully up in what the lecturer had to tell them, and in many cases the students provokingly accompanied the lecturer throughout his address with the paper in their hands. Under such circumstances it is not surprising that the lectures fell very flat indeed, or that the professors who had undertaken the duty of delivering addresses were subject to a succession of comments and jests which scarcely tended to encourage them in their work."

Election of Assistant Surgeons at the London Hospital.

WE have received, in reference to our last week's comment, an "indignant protest" from a gentleman who is in a position to know, and who declares we are mistaken in thinking the staff were consulted. Another correspondent says most of the staff were out of town. A third declares that only four persons were in the committee room, and that the whole affair was "hocus-pocus." We thought we had full authority for the version we gave, and should say no more but for the position of our correspondents, who have all worked for the hospital in some way or other, and have its interests at heart. Under these circumstances we will make further inquiry; for it is obvious that with a reputation for being, as one writes, "the only out-and-out independent and fearless Medical Journal," we must be cautious. Whether the only one or not, we are fearless and independent; and, if we have been led into approbation of anything by mistake, are by no means afraid to confess it.

DR. MAUTNER has been elected to the chair of ophthalmic surgery in the University of Innsbruck, the prohibitory clause against Jews occupying any Professorship in an Austrian University having been abolished. The authorities may be congratulated upon the result of this measure of liberality.

By telegram we learn that cholera has broken out afresh among H er Majesty's 41st Regiment at Subathoo. The scourge has also reappeared at Lucknow, this time among the Lancers, who have gone out into camp. Surgeon-Major Batson has succumbed to the malady.

Scotch Universities.

THE Scottish Universities' Union, according to Monday's papers, has resolved to invite Mr. John Stuart Mill to become a candidate for Glasgow and Aberdeen; and in the event of a vacancy, which is expected to occur, Dr. Prosser James for Edinburgh and St. Andrew's.

It is stated, on the authority of the *Hindoo Patriot*, that in order to escape registration under the Contagious Diseases Act, many dancing girls have induced Mussulmans to marry them by the *nikra* form.

THE *Gazette* of Tuesday week records the name of Thomas W. Phillips as one of the successful candidates for the Whitworth Scholarships. These Scholarships are worth £100 a year, and are tenable for three years. Mr. Phillips is a student of the Royal College of Science for Ireland.

M. MAREY, the well-known inventor of the sphygmograph, and the distinguished physiologist, has been selected by the Paris Academy of Sciences to succeed Flourens in the Chair of Physiology in the College of France.

THE lady doctors are making a new claim. The daily papers tell us that at Berlin a female doctor is in practice. It appears, however, that the individual in question is only a dentist, with a diploma from a dental college in Philadelphia, who has obtained permission to practise dentistry in the Prussian capital.

THE post-mortem examination of Marshal Niel has revealed the existence of four large calculi in the bladder. M. Nélaton had diagnosed the presence of many calculi during life. Two of these had been crushed by the lithotrite, but the weakness of the patient forbade the continuance of the operation.

AN evening paper protests against the growing custom of dilating in the newspapers on the illnesses of eminent men, and blames their doctors. We believe the *Lancet* should be blamed for encouraging this by its perpetual pretended information on the symptoms of disease in eminent persons, the information in question being only guesses. Who ever believed that the Emperor Napoleon communicated anything to that journal's correspondent?

WE learn that Professor Boehm, of Berlin, is in a desperate condition. His name may probably add one to the list of victims who have succumbed to the perilous duties of our profession. Scarcely ten days ago, in dissecting a subject in the presence of his pupils, he wounded his hand with a scalpel, but so slightly that he omitted to cauterize the wound or adopt other precautions. Two days afterwards the hand became the seat of a great swelling, and since that time every means employed to arrest the disease have been completely in vain.

EXTERN MATERNITIES AND LYING-IN HOSPITALS.

A REPLY TO CRITICISMS ON A COMMUNICATION TO THE DUBLIN OBSTETRICAL SOCIETY.

By EVORY KENNEDY, M.D., F.K.Q.C.P.

(Continued from page 265.)

THE second group described, that produced by noxious vegetable exhalations or poisons, is in simple ague the form in which we are most familiar with it; a disease that retains the germ of the poison for a long time in the system, lying latent for weeks, months, or longer, and seizing the patient at intervals, apparently capriciously; although the seizures generally recur on exposure to an ague or swampy district. This, however, may be looked upon as a fresh poisoning in a susceptible patient. This class of case is incapable, generally, of communicating its poison to another. In the class of diseases ascribable to foul animal poison, typhoid fever is conspicuous, and this disease is now well known not to be communicable by contagion. Not so typhus; it is purely a contagious disease, generated and developed in crowded and animal-tainted atmospheres, especially in those predisposed to it by debilitating habits. Like erysipelas and metria, it is a disease which may be either communicated to the patient, extending to her from another contaminated or poisoned patient, directly or indirectly; or it may be, as we have stated in our first paper on metria, generated in the patient herself when exposed to the influences that generate and develop it.

Now, the reasoning resulting from this bird's-eye view of these zymotic diseases amounts to this, that we have had hitherto very vague and indistinct notions of epidemic, endemic, and contagious diseases as to their laws and habits of generation, development, and extension or spread. Our want of precision upon them has led to most disastrous results, by causing us to look upon diseases as epidemic, and consequently beyond our control and prevention, when they were due to endemic causes that were easily remediable, or to contagion that had only to be preventive by strict attention to separation of the diseased from the healthy. The light that the investigation of the habits of cholera in its generation in crowded caravans amid the fetid Indian rivers, those of yellow fever in New Orleans, and those of plague at the sepulchre and haunts of the pilgrims in Egypt, has thrown upon the so-called epidemics, has gone a step towards correcting our views on this subject of epidemic and contagious influences — both influences preventable in their character, and which are the root of our enormous mortality and scourging by diseases which belong to their groups. What says an able writer on these zymotic diseases, in a recent number of that excellent popular journal the *Echo*, showing us that the public are becoming alive to these distinctions, although we may shut our eyes to them? In commenting upon Dr. Farr's admirable *résumé* of the causes of death in 1867, he writes:—"The origin of these diseases may be traced to the propagation of certain molecular atoms, not as yet scientifically classed or understood." (This, I may say, is scarcely a matter of astonishment, when in attempting to investigate this subject by bringing Dumas' views upon isomerism to bear upon them, the bare attempt was ridiculed as beyond our comprehension by a worthy and excellent friend of mine, Dr. Beatty, who, at no distant period, Sir, sat in your chair, and at a more recent one graced the chair of the President of this College, but who evidently thinks otherwise.) To return to the *Echo*—"It may be traced," he says, following Dr. Farr, "to certain living molecular atoms, not as yet sufficiently classed or understood, which, entering into man's body, transmute his tissues into their own substance, so that he can no longer live his own

life. The process is analogous to fermentation, and each zymotic atom is the little leaven that leavens the whole lump. Hence"—(he continues, in language plain enough, I am sure, but I fear not plain enough to convince an unwilling audience)—"Hence the danger of overcrowding, for the aggregation of numbers within narrow limits facilitates the transmission of the seeds of the disease."

Dr. Stokes admits that if I establish my position of the relation between the number of women delivered under one roof and the mortality, that then he must admit that zymotic disease acquires a great impulse from crowding, and on the same grounds also, that he must believe with me that the parturient woman has in herself a power of generating a poison which infects herself, and which produces a similar process by contagion in her neighbours. Now, I submit I have proved this relation to a demonstration by the enumeration of the 111 years' statistics of the Lying-in Hospital, and disproved its converse, which was unnecessary, as the proof of the affirmative was sufficient, by reference to the most authentic and reliable sources of information available, notwithstanding the few instances adduced to the contrary by certain of my commentators. But lest he require further evidence, I may refer him to Dr. Farr's last report just published, in which he will find in contrast to the grim death-rate, 1 in 31 of the Dublin Lying-in Hospital for the last fifteen years, Dr. Farr gives as the average of the last twenty-one years in England and Wales, the rate of mortality in child-birth as 1 in 200. In the healthier parts of England there are 43 deaths in 10,000 deliveries, or 1 in 232; in Wales the deaths amount to 61 in 10,000, or 1 in 164, which difference is ascribed to what may be called the civilization of the districts, the three last years in England and Wales being in 223. Thus although the general average of twenty years as improved throughout England and Wales by 1 in 23, it has in the last twenty years nearly doubled in the Lying-in Hospital.

Sir, although Dr. Stokes arrives at the conclusion that self-poisoning in puerperal fever is not proven, there are those who have thought deeply and written well upon this subject who are of a totally different opinion. Dr. Graily Hewitt, for instance, who has written more to the point in 21 pages of pamphlet upon the disease than any writer I am acquainted with, says:—"It is impossible to escape the conclusion that it consists in nothing more or less than an introduction into the general circulating fluid of a poisonous material of animal origin—that it is a form of pyemia, for the production of which the minutest portion of the morbid agent may prove sufficient." But, Sir, he goes further, and agrees with me in the self-poisoning. He says:—"That puerperal fever may occur in a well-marked form, and apart from such introduction from without of morbid material, is undoubted, but in such cases the explanation is virtually the same—the secretions from the surface of the uterus may become fetid, and may also be absorbed, in which case we have the idiopathic disease."

But Dr. Hewitt is not the only physician who has arrived at these conclusions, had we time to dwell upon them.

Dr. Stage, of Copenhagen, after treating of catarrhal affections, and uterine lesions in particular, in connexion with sporadic metria, in which he quotes Winckle, adds:—"The explanation of almost all these cases is, therefore, this, that the individual herself, in some mode or other, develops putrid matters, which are absorbed, and produce an infection—the so-called self-infection, in contrast to an infection from without.

Sir, there are some facts so conclusive to our mind that they do not require proof, and some equally convincing although they do not admit of proof. Let the learned professor but, look to the sun descending behind the horizon this evening, and then prove to me that he will ever see it on the morrow; but does he doubt it? Sir, although I draw his recollection

to this fact, I am not prepared to say, nor is he perhaps prepared to deny, that the principle of self-poisoning does not admit of proof conclusive to the mind of any reasoning man. Can he deny it in empyema? can he deny it in syphilis? Then why deny it in the case of metria, which, to my mind, is the most conclusive of all? Let us test it by the simplest rule of evidence, as glanced at by himself. There is one axiom upon which all jurists agree, an axiom which rules the decisions of our judges in dealing with our lives and property, as laid down by Lord Mansfield:—"As mathematical or absolute certainty is seldom to be attained in human affairs, reason and public utility require that judges and all mankind, in forming their opinion of the truth of facts, should be regulated by the superior number of probabilities, on the one side or the other, whether the amount of probabilities be expressed in words or arguments, by figures or numbers."

Again, Philips says:—"It is of the utmost importance to bear in mind that when a number of independent circumstances point to the same conclusion, the probability of the justness of that conclusion is not the sum of the simple probabilities of those circumstances, but is the compound result of them."

Now, testing the comparison of proof between the probability of poisoning by atmospheric or epidemic influence, with self-poisoning by an inherent generating power in the individual attacked sporadically by metria, when no other case in the district is attacked, who can for one moment hesitate in concluding, after what has preceded on the subject, that, with Mansfield, the superior number of probabilities—and, with Philips, the compound result of them—go to confirm the self-poisoning; whilst, with Butterworth, the force and effect of the circumstantial evidence depending upon the incompatibility of the explanation by atmospheric influence, or in fact upon any other supposition, reduces anything else to an approximation to an *argumentum ad absurdum*?

Sir, Dr. Stokes, as others of my commentators have done, has availed himself of the opportunity afforded by this discussion of pronouncing a censure upon the Registrar-General's Department. He says, "The reliability of the returns of death to the Registrar, as far as puerperal fever is concerned, is worth very little." "I can state that, from long experience. Now, I think it hardly fair to compare these statistics with those of a regular hospital." Such a condemnation as this from a physician of Dr. Stokes' weight and eminence, is no trifling matter, and yet Farr, Wilde, Donnelly, and Burke, are not men likely to have lent themselves to the compilation or circulation of unreliable returns, or statistics that would be worth very little. I am quite aware that in all statistics capable of collection errors must creep in; nay, more, that the statistics collected at present are capable of much improvement. Dr. Farr himself uses nearly as strong language on this subject as Dr. Stokes. I am also aware that in determining the exact class of case which should be denominated puerperal fever, a difficulty often arose, but this difficulty applied equally in the hospital returns as those out of hospital. Indeed, Dr. Stokes seems to have admitted this when he adds, "It also seems to me that we are very deficient in accurate statistics as to the mortality from puerperal fever in hospitals and private practice." If such be the case I look upon Dr. Stokes' objection to the comparison of the statistics in and out of hospital as untenable, on his own line of reasoning; as the same elements of what he terms unreliability and worthlessness extend to both. In adducing this answer to Dr. Stokes' objection, whilst I freely admit that a difficulty did exist in statistics classed under the head of puerperal fever which applied equally to all statistics, a difficulty which is much remedied by adopting the general nomen of metria, I object by my silence to appear to approve of the language applied to the Registrar-General, and to the wholesale stacks

made upon a valuable department of the State, which, as scientific men interested in the acquisition of sound knowledge, to constitute the basis of our reasoning in diseases, it is so much our object to sustain, and our duty to respect.

We have now a matter to deal with in Dr. Stokes' statement, the consideration of which no doubt will go some length in explaining the line of argument he has adopted in this discussion. He utters the following language which, with the weight of his authority, would prove conclusive, were it not that he himself so markedly disclaimed all knowledge of obstetrical practice in his opening observations:—"Now," he says, "If the mortality in private practice with all these favourable circumstances, be as great or greater; which I believe it to be, than in the lying-in hospitals, what becomes of the argument that the fatality is in proportion to the number congregated under one roof?" Now, I cannot for the life of me dismiss the idea that Dr. Stokes has by some unusual to him obscurity of thought confounded the words greater in degree and greater in quantity, or absolutely greater, and what leads to this conclusion is that in the preceding sentence he says, "I have been repeatedly called in consultation to cases of puerperal fever in the better class of life, and I am sorry to say the result is, that in these forty years I have never seen one case of puerperal fever in private practice that was not fatal; not one."

(To be continued.)

Correspondence.

LARGE FAMILIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Allow me to say that I cannot agree with your correspondent, whose brief remarks upon this subject you quote on the 29th ult. I do not see anything extraordinary or improper in the use which "W. C." has made in your previous number of the word "diabolical;" it would certainly be a bad pun if it had any reference to the Dialectical Society. My impression, upon reading "W. C.'s" remarks was, that he employed the word "diabolical" in the sense (at the same time deprecating that view) in which it is used by the advocates of large families, who appear to be at a loss for words strong enough—notwithstanding the hard names they do use—to express their disapprobation of the efforts made by a few far-seeing individuals, to spread more enlightened views on this subject.

Is it not preposterous to find that a large family is made by one man a reason for his claiming our charity, and by another an excuse for his commission of a crime! and yet both these baits are, over and over again, swallowed by a gullible public.

It is not uncommon to see advertisements to the following effect:—"A case for the benevolent! An educated man, with a large young family, in great distress, appeals, &c., &c." All I can say is, that this gentleman's education has been of very little use to him, if it has not taught him, with other things, the wisdom, not to say the duty, of keeping his body in subjection to his reason. Large families are especially blameable in a clergyman, whose case gave occasion for the admirable remarks which have suggested this letter. He who studies the Scripture, and whose life should be an example to his flock, should surely know how to be "moderate in all things," more particularly with regard to the most important functions of his being.

Again, to give an illustration of the "large family plea," in punitive cases, in which domestic or other servants, abuse the confidence reposed in them by robbing their masters, and are convicted, the culprit will urge the fact of his "large family" as an extenuating circumstance in his favour!

Now, I wish to say very little upon the more delicate questions involved in this subject; a great deal might be said on those points which include physiological and moral considerations. I will simply and very briefly intimate the direction which I think such a discussion ought to take. 1. The present prevailing error should be confuted, that the marriage ceremony

sanctions an immoderate indulgence of the passions. 2. A man has no right to bring children into existence, unless he can not only maintain them in his own position in life, but attend to their mental and moral cultivation, and do his part to make them in all respects good and useful citizens of the world. 3. A man has no right, by virtue of his wife's marriage vow, to render her delicate and unequal to perform the numerous duties—among which are the offices of maternity—for which many a woman is incapacitated by reason of the husband's demands upon her, in order to gratify the inordinate exactions of his unchecked desires. 4. Many wives yield in this matter, in opposition to the dictates of their own more refined natures, partly from a vague impression—which the education of women only tends to strengthen—that they are body and soul the property of the husband; and partly again from an instinctive feeling and an apprehension of the man-nature, that the way to keep a husband true is to deny him nothing.

The comment which suggests itself upon the last proposition is this:—that if the devotion of the wife did have its proper effect upon the husband, there would be less to regret, if even the penalty of such devotion were loss of health and a premature decay of beauty and vigour. A true wife would consider the preservation of her husband's fidelity well worth the sacrifice; but in the great majority of cases, the man who is incontinent in marriage is also inconstant to his wife, just because he exercises no control over himself in the indulgence of his passions; and this lawless excess, unrestrained by any moral or prudential considerations, is, in the opinion of all thoughtful and right-minded persons, *Prostitution*, whether legalised by marriage or not.

I am, Sir, yours faithfully,

October 1st.

PRUDENTIA.

THE LANCET AGAIN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—What must the eminent and world-wide reputed consulting physicians and surgeons of Dublin think of the following spicy extracts from the *Lancet* of last week?—"We doubt the value of the opinion of a surgeon who has no medical knowledge, or of that of a physician who should be foolish enough to glory in knowing nothing in surgery." Again, "the patient in the ordinary social conditions of life can have only one medical adviser." "His medical adviser must be a complete one. He must know both physic and surgery, and be ready either to set a fracture, or treat a case of dysentery or pneumonia." Imagine our great Stokes superseding Professor Robert Smith, or Sir Dominic Corrigan becoming an accoucheur, or Mr. Robert Adams acting the apothecary, for the *Lancet* places all on the one and the same level. The hallucinations of the *Lancet* in one column are beautifully neutralised by wanderings about lady-birds on the opposite. Because the editor of the *Lancet* objects to *pure* surgeons and *pure* physicians, it is no excuse for writing *pure* nonsense.

Your obedient servant,

Oct. 1, 1869.

PODALIRIUS.

ADDRESS TO STUDENTS, BY MR. CHARLES DICKENS.

THE Midland Institute this year has secured Mr. Charles Dickens for its President, and he last week delivered an inaugural address to the students. At this season when addresses to medical students are plentiful as blackberries, it may not be uninteresting to turn a moment's attention to more general studies as represented in addresses to other students than medical. In the course of his address Mr. Dickens offered much advice that will be suitable to all. We extract the following passage as a specimen, and refer our readers to the reports of the daily papers for more:—

"To the students of your industrial classes generally I have had it in my mind, first, to commend the short motto, in two words, 'Courage, Persevere.' (Cheers.) This is the motto of a friend and worker. Not because the eyes of Europe are upon them, for I don't in the least believe it—(laughter)—nor because the eyes of even England are upon them, for I don't in the least believe it; not because their doings will be proclaimed with blast of trumpet at street corners, for no such musical performances will take place—(laughter)—not because self-improvement is at all certain to lead to worldly

success, but simply because it is good and right of itself—(hear, hear)—and because, being so, it does assuredly bring with it its own resources and its own rewards. I would further commend to them a very wise and witty piece of advice on the conduct of the understanding which was given more than half a century ago by the Rev. Sydney Smith—wisest and wittiest of the friends I have lost. He says—and he is speaking, you will please understand, as I speak, to a school of volunteer students—he says, ‘There is a piece of foppery which is to be cautiously guarded against, the foppery of universality, of knowing all sciences and excelling in all arts—chemistry, mathematics, algebra, dancing, history, reasoning, riding, fencing, Low Dutch, High Dutch, and natural philosophy. (Laughter.) In short, the modern precept of education very often is, ‘Take the Admirable Crichton for your model; I would have you ignorant of nothing.’ ‘Now,’ says he, ‘my advice, on the contrary, is, to have the courage to be ignorant of a great number of things, in order that you may avoid the calamity of being ignorant of everything.’ (Laughter and cheers.) To this I would superadd a little truth, which holds equally good of my own life and the life of every eminent man I have ever known. The one serviceable, safe, certain, remunerative, attainable quality in every study and in every pursuit is the quality of attention. My own invention or imagination, such as it is, I can most truthfully assure you, would never have served me as it has but for the habit of common-place, humble, patient, daily, toiling, drudging attention. (Hear, hear, and cheers.) Genius, vivacity, quickness of penetration, brilliancy in association of ideas—such mental qualities, like the qualities of the apparition of the externally armed head in ‘Macbeth,’ will not be commanded; but attention, after due term of submissive service, always will. Like certain plants which the poorest peasant may grow in the poorest soil, it can be cultivated by any one, and it is certain in its own good season to bring forth flowers and fruit. I can most truthfully assure you, by the bye, that this eulogium on attention is so far quite disinterested on my part as that it has not the least reference whatever to the attention with which you have honoured me. (Laughter.)’

SOCIAL SCIENCE CONGRESS.

THE annual meeting of the Social Science Association has been held during the week. It is impossible in the present state of our columns to report its proceedings at length, and we shall therefore content ourselves with collecting some of the points of most interest to our readers.

In the course of his inaugural address, Sir S. Northcote, President, referring to the Health Department, said he attached the highest importance to the Department of Public Health, for no amount of individual care or of individual skill can do what is wanted in this matter. “Combined action is necessary to secure to the great masses of our population the first conditions of a sound sanitary state to check the propagation of infectious disorders, to prevent over-crowding in dwelling-houses, to provide an adequate supply of pure and wholesome water, and otherwise to bring all the forces of civilization into play in order to counteract the evils which civilization brings in its train. It is much to be regretted that we have not as yet a thoroughly well organized department of the Government, charged with the duty of superintending our sanitary system. There is, I am convinced, abundance of work for a Minister of Health. The time is probably at hand when three new Ministries must be created: a Ministry of Health, a Ministry of Education, and perhaps (though on this point I speak with diffidence) a Ministry of Justice. The present day, however, is the day of Royal Commissions; that of Ministries is yet to come. More than one such Commission is now inquiring into questions affecting the public health. The most important is that presided over by Sir Charles Alderley, which is considering the consolidation of our very complicated sanitary laws, and the completion of our system of sanitary organization. Those who are in the habit of paying attention to the connection between the growth of national habits and the growth of national language will not have failed to notice the recent introduction among us of the phrase State medicine, a phrase absolutely new to many of us, and perhaps still imperfectly understood by the general public. State medicine, in short, as a member of the committee well expresses it, consists in the application of medical knowledge

and skill to the benefit of communities, which is obviously a very different thing from their application to the benefit of individuals in private or curative medicine. It is difficult to assign a limit to the demands which the State might with advantage make upon the time and intelligence of a well-organized Medical Civil Service. These remarks naturally suggest two reflections. In the first place, we seem to want a body of men able to withdraw themselves without inconvenience from the engrossing demands of private practice, and to devote themselves to the especial study of the public questions which require medical attention. In the second place, when we have got our Medical Civil Service, how are we to turn it to the best account? If we are to have an organized medical staff spread over the face of the land, some kind of local organization will be required for it; the machinery cannot be wholly worked from London.”

EDUCATION.

In the Education Department there was a debate on the question whether an unsectarian scheme of education was inconsistent with religious teaching.

CONTAGIOUS DISEASES.

The Health Department spent one day in discussing the action of the Government in connection with the spread of contagious diseases.

In the same Department a discussion resulted in an affirmative answer being given to the question—Can Government beneficially further interfere to limit the spread of infectious diseases? On the motion of Mr. George Godwin, a resolution was passed to the effect, “That Government ought speedily and strongly to interfere to afford to the various classes of the community the benefits of sanitary science.” The resolution, seconded by Dr. James, was carried.

LADIES' CONFERENCE.

The Ladies' Conference met at 3 o'clock this afternoon with closed doors. The subjects discussed were workhouse visiting, secret drinking, female intemperance, the training of nurses, and other subjects of a kindred nature. Miss Carpenter presided.

Miss Hill gave a description of the Bristol Industrial Schools for Girls, and the Lady Superintendent explained the operations of the Red Lodge Reformatory, which was founded by Miss Carpenter fifteen years since.

POOR-LAW ADMINISTRATION.

After a long discussion on the papers read in the Economy and Trade Department, the following resolutions were carried:—“That the section recommends for the consideration of the General Council the propriety of urging upon the authorities the employment of educated women in the inspection of workhouses and hospitals, as being absolutely needful for the proper and efficient management of such institutions.” “That it be suggested to the Council that there is an absolute necessity for the due relief of poverty, and that there should be a charitable committee acting in conjunction with boards of guardians, and that the old house visitation should form an essential part of poor relief.”

INFANTICIDE.

In the Reformatory and Repression of Crime Section, presided over by Sir Eardley Wilmot, the possibility of diminishing infanticide by legislative enactment was discussed. Dr. Lankester urged that some legislative measures should be devised to reduce the number of child murders, which was now so excessively high.

A paper, by Mrs. Maine, suggested, in preference, the influence of homes for women who had fallen.

INTEMPERANCE.

In the Health Department it was resolved that legislative measures ought to be passed for shutting up cases of uncontrollable drunkenness. Papers were read by Dr. Symonds and Dr. Gairdner. A strong supporter of the resolution was found in Professor Newman, who spoke as an exponent of the views of the United Kingdom Alliance. In connection with this gentleman it may be observed that two Brahmins of the very highest caste, attending the congress, had heard so much of him and his works in Calcutta that they insisted upon being specially introduced.

The question of Hospital Management was also under discussion, a voluntary paper being read by Miss Duch. Dr.

Lankester was of opinion that patients (when practicable) should be treated at home instead of in hospitals. Mr. Whitwell argued that large hospitals were not desirable, and a tolerably general opinion was expressed that small wards were preferable to large ones. The department proceeded to deal with the subject of vaccination.

HEALTH.

Dr. Alfred Carpenter read a voluntary paper "On some points in the Medical Aspect, and the Physiology of Sewage Irrigation." After a lucid explanation of what irrigation was, and answering some of the objections that had been raised to sewage farms, Mr. Carpenter explained how sewage irrigation might be extensively adopted without danger to the health of the inhabitants.

Mr. J. V. N. Bazalgette read a voluntary paper "On the Sewage Evil, its Causes and Effects, with Suggestions for its Remedy." He said there had been few subjects so much written about during the last few years as the subject before them. Pamphlets, blue books, reports, and newspaper correspondence had already accumulated a mass of contending opinions, before which local boards and other authorities entrusted with the care of public health paled, and whilst all were unanimous in the opinion that "something must be done," almost all were equally irresolute as to what particular mode was the best, and were waiting for something to turn up. That injurious delay in disposing of the sewage of towns arose in a great measure from the desire of individuals to stereotype some one particular measure. As Dr. Sangrads insisted upon his celebrated specific, to the manifest advantage of the undertaker, so the irrigators, regardless of climate, insisted upon flooding the neighbourhoods of all towns with the crude contents of the sewers, as though marvellous crops and a rank herbage were the only desiderata, and the certain precursors of the millennium. There were instances in which irrigation might be efficient and economical; but from what he had seen he would not admit any system as being desirable which did not begin its operations at deodorising the sewage.

Mr. Sneade Browne read a paper "On the Ventilation of the Sewers of Clifton."

Mr. W. Hope read a paper on town sewage. He recommended the adoption of a resolution urging the Government to adopt some measure for utilising the sewage of towns instead of allowing it to run into rivers.

Mr. Brudenell Carter read a paper on the sewage works of Stroud.

ABSTRACT OF INTRODUCTORY LECTURES.

ST. GEORGE'S.

At St. George's Hospital the lecture was delivered by Dr. Wadham, in the new theatre. Entering at some length into a consideration of the nature and responsibilities of the Profession, and the prospects it afforded to those who thoroughly qualified themselves for its practice, the lecturer said:—"Even if you become a good physician, or a skilful surgeon, you must not imagine that with industry and rectitude your success is certain, the utmost you can do being to deserve it. For although it rarely happens that in the higher branches of the Profession any man obtains the general confidence of the public—and certainly never that and the confidence of the Profession—without deserving it, it often occurs that those whom the Profession respect the public ignore, and that the more numerous prizes are awarded to assertion and assurance, and not to modesty and merit—the public in this respect resembling the unjust judge in its nature, and those who obtain its ear having much of the irrepressible disposition which distinguished the importunate widow." After pointing out how, as faithful disciples, they should follow science, Dr. Wadham warned them against seductive theories, and against choosing shadows. In the concluding portion of his address, Dr. Wadham again addressed some words of advice and encouragement to the students, entering upon a most honourable, but still most arduous Profession.

KING'S COLLEGE.

The Introductory Lecture of the Session at this College was delivered by Professor Johnson, in the presence of the

Principal and heads of the Institution, and a rather limited general audience. Having regard to the mixed character of his auditory, the Professor chose for the subject of his discourse a general exposition of the ends and method of the science and art of medicine; but before approaching this theme he referred in suitable terms to the loss which the College had sustained by Dr. Beale's resignation of the Chair of Physiology, and to the appointment of Dr. Rutherford, of the University of Edinburgh, as his successor. At the same time he congratulated himself and his hearers upon this circumstance—that Dr. Beale retained his position at the Hospital, as well as the Chair of Pathological Anatomy, and that Drs. Kelly and Yeo had been appointed Assistant-Physicians in the Hospital in the place of Dr. Thom. A reference to the discovery of the means of avoiding pain by local or general anæsthesia, vaccination—the most splendid instance of preventive medical treatment on record—and the non-restraint system of treating the insane, introduced into the asylums of this country by Dr. Conolly, who followed in the footsteps of Pinell and William Tuke, brought the lecturer to a consideration of the mind itself, which he refused to believe is merely the material or product of a highly-organised protoplasm. A few words of advice were uttered as to the method which the students should adopt in the pursuit of their studies; and the discourse was brought to a close by an exhortation to them to remember that the main object of their career is the discovery of truth for the exaltation of the Creator, and the relief of human suffering, and an injunction to "prove all things and hold fast that which is good."

MIDDLESEX.

DR. LIVEING delivered the Inaugural Lecture. He began by referring to the advantage of having a good preliminary education before entering as a student for the Profession of Medicine, in the course of which he touched on the present state of the Profession. With regard to the licensing corporations, he thought they ought to be reduced into a uniform system. There were at present eighteen or nineteen such corporations, and if they all required the same standard before granting a diploma, he did not think that any objection need be made. But that was not the case. But whilst advocating uniformity in the licensing department, he was opposed to the restriction of medical schools. The French system, under which all the medical students were taught in three or four great schools, was not desirable. There the result was that the pupils followed the system and the practice of a few masters. He thought it better that there should be more variety and more individuality. With regard to the admission of females to the Medical Profession, he thought that all his hearers would agree with him to this extent, that it was desirable to extend the field of female employment. Then came the question: Was the Medical Profession a proper sphere for female employment? Time alone could answer that question. In the meantime, he did not think that the Medical Profession or the public would be justified in refusing them a fair trial. In all probability some of the medical colleges would soon be open to females. All he would say was, that if they were to be entrusted with the care of human ailments, they must receive the same sound education as men. In conclusion, he entreated the medical students to hold high the honour and status of the Profession, and never to degrade it to the art of charlatany or humbug.

ST. MARY'S.

DR. W. B. CHEADLE delivered the Introductory Address at St. Mary's Hospital, Paddington. When he commenced the study of medicine, towards the end of a university course, having enjoyed to the full all the advantages of education under the guidance of able tutors, he found himself utterly destitute of such knowledge as could be directly of service to him in his new pursuit. At an age when he ought to have gone through all the drudgery of elementary study, he had to commence again with the merest rudiments of natural science. Could any one doubt that every man ought to be provided with a reasonable amount of precise general knowledge of the world in which he had to live, where phenomena take place according to fixed laws, in obedience to which all his work has to be done? He ought

to be acquainted with the properties of the materials he has to work with, and the conditions under which that work has to be accomplished. The general deficiency in this respect affected the Medical Profession more severely than any other. Again, unless the public obtained some reliable acquaintance with primary scientific truths, it was impossible for them to distinguish between what was certain in medicine and what was but useless theory. They were necessarily credulous and superstitious on such a subject; they became the dupes of imposture, and thus it happened that rogues and charlatans obtained the success which was the due of honest men. The universities had fairly begun the necessary reforms. In schools, however, the change had been very partial and incomplete. He strongly urged the necessity of a diligent observation of disease at the bedside—a branch of study too apt to be pushed aside in the crowd of subjects which engrossed the attention of the students during the three years of their hospital course. Having dealt at considerable length with the present state of medical knowledge, Dr. Cheadle concluded his address by drawing some bright prospects of the future—of honour to be won and wealth to be gained as the reward of earnest study and an enlightened practice of the Profession.

NOTICES TO CORRESPONDENTS.

In all cases when proofs are sent, it is of the utmost importance for them to be immediately returned.

CORRESPONDENTS not answered should look to the answers the following week.

TO SUBSCRIBERS.—Those gentlemen who have not paid their subscriptions for last year are respectfully reminded of the omission.

* * * We must beg the indulgence of several contributors and correspondents whose communications are unavoidably postponed in consequence of the pressure on our space, caused by the opening of the London Schools of Medicine.

STUDENTS' TEXT BOOKS.—We are reluctantly compelled to hold over the continuation of our Special Report on this subject—of which two portions have appeared in our last two numbers.

FAIR FEES.—Several correspondents suggest that the shabby fellow who refused to pay M.D., M.R.C.P., deserves to be prosecuted.

A.B.—The writer of the article is well acquainted with the facts. F.S.—See our student's number. It supplies you with just the advice you ask.

L.R.C.P.—Fellows must not sue for fees. After four years' membership, you are eligible for election with the fellowship.

Mr. J. WARING-CURRAN, Sutton.—The type was broken up before we received your application for slips of your "Surgical Memoranda," or we should have been happy to send them.

Mr. J. PERRETT.—The utility of your new Patent Feeding Bottle will be practically tested before an opinion is given.

TO STUDENTS.—Information relative to the Westminster Hospital Medical School can be obtained of Mr. Holthouse, 4 Old Burlington street, W., and not at 1 Storey's Gate, the Dean's former residence—accidentally inserted in our last.

Dr. KISSY's letter was delayed by the issue of our Student's number. It appeared in our last.

APOTHECARY TO IRISH COUNTY INFIRMARY.—The office is, in many cases, held by persons who have no apothecary licence, and, unless the governor and company venture on enforcing their powers, no question as to their eligibility need arise. In law every person practising pharmacy in Ireland must be a licentiate apothecary, and, in some cases of public institutions, the company has insisted on the possession of, at least, one assistant's certificate.

APPOINTMENTS.

BAMFORD, Mr. J., Resident Dispenser to the Brixton, Streatham hill, and Herne hill Dispensary.

BATTERSBY, W. E., A.B., M.B., Demonstrator of Anatomy at the Ledwith School of Anatomy, Medicine, and Surgery, Dublin, vice F. V. McDowell, L.R.C.S.I., Medical Officer to the Ballinacloyler and Newtown Dispensary District of the Carlow Union.

BUSIGNY, C. E., M.R.C.S.E., House-Surgeon and Secretary to the Worcester Dispensary, vice C. Gargory, M.R.C.S.E., Medical Officer to the Tonbridge Union.

THE UNITED KINGDOM TEMPERANCE AND GENERAL PROVIDENT INSTITUTION.

THIS INSTITUTION was Established A.D. 1840, on the principle of purely Mutual Assurance, the founders believing that to be the most equitable and fair to its Members. Without either of the means of extension resorted to by many kindred Institutions such as amalgamation with other Companies, or extensive and constant advertising—and notwithstanding the fierce competition of Life Assurance Companies for public favour, this Institution has worked its way gradually and steadily, until it has attained its present high position; thereby showing the great confidence and estimation in which it has been held by the public.

The Society has an Accumulated Capital of £1,100,000, and an Annual Income of £220,000. The sum of £691,618 18s. has been paid for Claims through death.

On the 31st December, 1868, the Policies in force covered Assurances to the amount of £5,514,961.

Prospectuses and Forms of Proposal, as well as Copies of the Directors' Report for the year 1868, with Balance Sheet, &c., can be had at the Head Office for Ireland, 88 Talbot street, Dublin.

R. D. KING,

Manager for Ireland,

To whom applications for Agencies may be addressed.

THE MANCHESTER FIRE INSURANCE COMPANY.

Established 1824.

CAPITAL ONE MILLION STERLING.

Chief Offices:—98 KING STREET, MANCHESTER,
96 CHEAPSIDE, LONDON.

* * * The cheerfulness and promptitude with which important losses have been paid by this Company are well known and admitted, it being the desire of the Directors to settle them with liberality and despatch. &

Branch Offices for Ireland:

88 TALBOT STREET, DUBLIN.

R. D. KING, Manager.

To whom all applications for Agencies should be addressed

J. J. GRAHAM AND CO.
BEG TO ACKNOWLEDGE with most grateful feelings the liberal and increasing patronage bestowed upon them by the Medical Profession, and to assure them that it is their constant aim to render themselves deserving of a continuance of their support.

J. J. GRAHAM AND CO. confine themselves strictly within the limits of the Pharmaceutical Profession, and under no circumstances do they take upon themselves Medical or Surgical duties, other than those performed by the Apothecary under Medical directions—namely, Cupping, Leeching, Blistering, &c.

As the value of a Prescription is completely dependent upon the therapeutic efficacy of the medicines ordered, J. J. G. and Co. are most particular in keeping up a stock of the purest Chemicals and freshest Pharmacopœia preparations. Every article used in the making up of Prescriptions procured from the first Houses regardless of cost, and such as are at all liable to adulteration tested before used; the Profession may therefore rest satisfied that the medicines prescribed will be of the best quality, and carefully compounded under the immediate superintendence of the Principal (J. J. Graham), who resides on the Premises and devotes his whole time and attention to the management, supervising the operations of the assistants, and who is accessible at all hours.

THE MEDICAL HALL, 30 WESTMORELAND STREET
ESTABLISHED A.D., 1821.

PURE TASTELESS COD-LIVER-OIL IMPORTED BY BEWLEY AND DRAPER.

IT is this OIL, the use of which is directed by the MEDICAL COUNCIL, and which is ordered by the BRITISH PHARMACOPEIA.

DR. PEREIRA

Says, "The FINEST OIL is THAT WHICH IS MOST DEVOID OF COLOUR, ODOUR, and FLAVOUR."—"No other Livers but those of the TRUE COD can be obtained for the preparation of Oil at Newfoundland," a fact which is the best guarantee of the GENUINENESS OF THIS OIL.

In bottles, price 1s., 1s. 6d., 2s. 6d. and 4s. 6d.

Sold by **BEWLEY and DRAPER,**
23 MARY STREET, DUBLIN.

And may be had from all respectable Apothecaries in Town and country.

HAMILTON, LONG, & CO.'S COD LIVER OIL of 1869.

THIS OIL, prepared by them since 1850, with the increasing approbation of the Profession and the Public, is extracted from the fresh Liver of the Channel Codfish, on their own Premises, and warranted perfectly pure.

H., L., and Co.'s ETHERISED COD LIVER OIL, now in general use, particularly suitable when the stomach is sensitive.

PREPARED BY

HAMILTON, LONG, & CO.,

THE STATE APOTHECARIES,

3 AND 4 LOWER SACKVILLE STREET,
107 GRAFTON STREET, DUBLIN,

AND

1 RATHMINES TERRACE, RATHMINES.

SIR J. MURRAY'S
PURE FLUID MAGNESIA
IS RECOMMENDED BY PHYSICIANS SINCE 1807 for Bile, Acidities, and Indigestion. They also order his **CODIAL CAMPHOR** (3 grs. per ounce) as the best restorative for weak nerves or low fevers. His **LEMON-SYRUP**, mixed with either Fluid, forms a brisk Aperient for any age—bottles 1s. and 2s. 6d. To guard against false liquids the Patentee's labels are subscribed "Sir J. MURRAY, Physician to the Lord Lieut."

MOST IMPORTANT TO FAMILIES
GUINNESS'S XXX PORTER.—J. BEBE invites attention to this Celebrated Porter in Bottle, being now specially ordered to invalids, for its nutriment and strengthening qualities; in fact it has been found, in great many instances, to supersede Wine in recruiting health and strength. Each Bottle is wired and tin-foiled, and is protected by his label and "Trade Mark." Prices are as follows.

Terms Cash.	Per doz.
Guinness's Celebrated XXX Porter (small bottles) ...	2s. 4d.
Guinness's Celebrated XXX Porter (large do.) ...	4s. 6d.

Ten Vans deliver daily in the city and suburbs, and orders sent by Railway to all parts of Ireland.

JOHN BEBE, Rectifying Distiller, Direct Wine and Brandy Importer,
18, THOMAS-STREET, DUBLIN.

The Medical Press & Circular.

ON REMEDIES USEFUL IN THE TREATMENT OF PHTHISIS.

By GODWIN W. TIMMS, M.D.,

One of the Physicians to the North London Consumption Hospital.

We cannot all of us be discoverers in science; we cannot all even hope to strike out new paths in the march of improvement; but every one of us, I believe, if we were so minded, could smooth some difficulty or clear away some obstruction. Grains of information collected by the patient industry of the many and brought into a common stock would add more to the wealth of science than the glittering nuggets which the more fortunate few occasionally turn up.

To add my contribution, I copy from my notes some hints on remedies useful in the treatment of phthisis.

COD LIVER OIL not being invariably attended by benefit, it becomes useful to be able to distinguish the cases in which its exhibition is most likely to be attended with success:—

1. In phthisis of middle and advanced life it is seldom of much use.

2. In phthisis occurring in the widow or widower* of a fatal case of consumption it is of no use.

3. It has failed at my hands most frequently in chronic cases of profuse expectoration, with little or no hectic.

On the other hand:—

1. Where there is much fever and little expectoration, cod-liver oil cannot be pushed to excess.

2. The younger the patient, the more obviously effectual is cod-liver oil. It is very valuable until the patient has reached adult age, less so but still useful up to middle life, and insignificant as a remedial agent after middle age is passed. It is the most useful of all drugs as a prophylactic and in the initiation of the malady, but gives less and less relief as the disease advances.

What is the best description of cold-liver oil? I have

found, after repeated observations, that the oil, which at ordinary temperatures is the most limpid, which runs in the smallest stream, produces the least disagreeable effects, such as flatulence and nausea. Its taste should be slightly fishy, without harshness or bitterness.

Is cod-liver oil digested? The only idea of digestion I can master is the partial or total solution of a solid—its conversion into an absorbable substance. Beef-tea digested is absorbed as to its fluid parts, and the solid residue is acted on by the digestive juices. We read continually of the digestion of cod-liver oil and of agents which assist its digestion; but this, I own, is unintelligible to me, except as to any solid residue which may remain after the absorption of its fluid parts. I suspect æther and brandy stimulate its absorption, according to a well-known law (endosmose), rather than promote its digestion. If there is any solid residue in cod-liver oil (stearine or margarine), I think it would be better to extract it before exhibition, than to employ agents to assist its assimilation.

Can long persistence in the use of cod-liver oil do any harm? I am sorry to say that I have observed in several cases of chronic phthisis, where the pulmonary and constitutional symptoms have disappeared under the long-continued use of cod-liver oil, the muscular system has degenerated, and weakness, palpitation, and irregular action of the heart have resulted. Hence occasional intermissions in its use (when a preparation of iron may be substituted) are advisable.

DILUTED HYDROCHLORIC ACID, in doses of twelve or fifteen drops every two hours, I have never found to fail in those persons who, not hereditarily phthisical after the decease of their husbands or wives by consumption, have presented themselves suffering with cough, profuse expectoration, hectic, and emaciation.

1. It is almost as invariably successful in those mixed cases in middle or advanced life, where attacks of bronchitis occur in the undeniably phthisical—cases which I have heard called tuberculous bronchitis.

2. It is a valuable remedy in members of a consumptive family of all ages, beginning to fall off with hectic, emaciation, and debility. It is the best substitute for

cod-liver oil in those who cannot or will not take the latter. In all cases it is of little use unless given in the above doses six or eight times a day.

BICHLORIDE OF MERCURY, in doses of one-fifteenth of a grain in distilled water with half an ounce of cod-liver oil three times a day immediately after meals, I have given in several thousand cases with the following general results. It has never in one single instance produced the slightest effect upon the salivary glands or on the gums, although it has been persevered in twelve months at a time.

It is of all medicines with which I am acquainted the most powerful in its influence upon the tuberculous diathesis. It is as powerful an alterative in chronic phthisis, and as useful as it is in the syphilitic constitution. It may be objected that the beneficial effect is confined to those cases of phthisis which have been induced by hereditary syphilitic taint. In answer to this I reply, that the great majority of instances of phthisis must be then referred to syphilis (which is absurd), for fully two-thirds of all cases of consumption benefit by the use of the bichloride. As in hydrochloric acid and the chlorate of potash, I refer its utility to the chlorine it contains, and believe that the only advantage of the combination is, that with mercury the chlorine is presented to the blood in a form capable of acting upon the morbid element more directly than in any other compound of chlorine. I have no desire that the profession should love mercury, but I do wish that they were skilful in its use, for then they would have no fear of it. I recommend only a tentative use of the bichloride in the small doses described above. No harm can come of a month's trial in any case, with or without cod-liver oil; and I believe that practitioners will be induced by the relief obtained to give it more and more perseveringly, as I myself have been led on to do for several years past. According to my experience, it will prolong life even where vomice are present; but its great efficacy is seen in those cases, much the most common of late years, in which the expectoration is least prominent as a symptom. In patients whose symptoms consist of gradual but decided emaciation, increasing dyspnoea, hectic, and dry cough, with the addition, in females, of amenorrhoea, the use of the bichloride with cod-liver oil will very often restore health.

As the morbid element in tuberculous blood consists of an excess of unexcreted tissue waste, it is evident that none of the excretions should be allowed to become defective, and the more so because the evil resulting is not immediately apparent, but only to be discovered in the failure of success in the treatment. Those excretions which are excited to extreme activity by the vis medicatrix should not be shut up directly, but the necessity of their continued excitement prevented by the encouragement of all the other excretions. Among the instruments of apparent present benefit, but of real ultimate mischief, may be enumerated, steel, quinine, bark, opiates, malt liquor, and strong wines. All these, by no means to be contemned at proper times, become mischievous agents when prescribed without limit and without a distinct purpose. As there is always a deprivation of the blood from the setting in of the disease, hearty feeding and steel are looked upon as always useful. If the only object were to restore the healthy quantity of red particles, or if their restoration would retard the disease, this would be correct; but unfortunately this is not so. Immediately the respiratory power becomes lessened by ever so little a deposit in the lungs, nature lessens the circulating material in proportion; and any interference of ours to increase the circulating material only disturbs the balance between the circulatory and respiratory functions. On the other hand, if we avoid all things which increase the circulating material, but enforce all those measures which increase the respiratory function, nature will raise the circulating material and adjust the balance between the two functions.

Hence we may sum up shortly our treatment of con-

sumption:—Light, simple, and nourishing diet, in quantity always in proportion to the appetite of the individual (the palate is an excellent guide, which we should be always afraid to offend), all wholesome fruits and vegetables, a moderate amount of thoroughly-cooked meat, and diluents, tea, milk, whey, &c., according to the patient's experience, avoiding all stimulants and forcing of the appetite. Regimen: excitement of the skin by constant cleanliness, friction, and woollen clothing; fresh air, sea air if possible; exercise of every kind, gymnastic exercises, singing, reading; the avoidance of every restriction by dress upon the chest-walls, and of indolence and self-indulgence of every kind; the exclusion of gas from all apartments inhabited by the invalid; early hours, and as short a sojourn as possible in the same atmosphere; hence it is better to take a short sleep in the day than to remain more than six or seven hours in the bedroom, the windows of which should never be shut except on particular occasions, or under peculiar circumstances.

Drug treatment. An obstinate cough with expectoration in the member of a consumptive family, unaccompanied by much general disturbance, is most successfully treated by twelve or fifteen drops of dilute hydrochloric acid in one ounce of water every two hours. Patients often declare that they taste the chlorine in the expectoration.

An obstinate dry cough, accompanied by emaciation, debility, and fever, is very successfully treated by half an ounce of cod-liver oil three times a day after meals, in a draught containing one-fifteenth of a grain of bichloride of mercury. Either of these remedies is good in all stages of the disease, with or without oil.

In children, cod-liver oil alone is very successful; as age advances, the remedial power of cod-liver oil is diminished.

In the middle-aged, and in consumption occurring in the survivor of a husband or wife dead of phthisis, the hydrochloric acid, in the doses mentioned above, is the most successful remedy.

Steel is only to be given for a few days at a time. All astringents, except for special objects, are injurious. The citrate or tartrate of soda or potash should be given occasionally, and these salines are quite as generally useful as steel.

Mild laxatives occasionally are very beneficial; pills of grey powder and rhubarb for the young and a mild aloetic pill for the middle-aged will tempt the practitioner who tries them to very frequent use. Trying to help towards the successful treatment of a few varieties of consumption, it would not become me to condemn any drugs recommended by other practitioners. So intractable is the disease, that every new remedy ought to have a fair trial. Familiar with the idea of patients being induced to swallow the urine of the boa constrictor and the pancreatic fluid of a pig, if a patient were to tell me that he had found benefit from imbibing the saliva of a goat, I should not hesitate to recommend him to persevere in its use.

Much more do I recommend most respectfully the practitioner who has found success from treatment by peroxide of hydrogen, the hypophosphites, chlorate of potash, &c., to persevere in their judicious use, until they can point out distinctly the cases in which they may be hopefully recommended.

All I can say is, that I have not been so fortunate as to find any decided results from their persevering exhibition.

ON A NEW PREPARATION OF PEPSINE.

By EDWARD LONG, L.A.H., DUBLIN.

DURING some recent investigations into the manufacture, relations, and general properties of pepsine, I was induced to make a solution in glycerine, somewhat after the manner of "Ellis' Rennet Wine," so much prescribed of late in this city. Many considerations led up to this idea, and the results more than realized my expectations.

In the ordinary process for making pepsine, there is necessarily used a considerable quantity of starch to produce a dry powder, which evidently opens the door to great adulteration, as it is difficult to detect the relative proportion of the active and passive constituents. As a consequence, we hear most discrepant opinions of the therapeutical value of pepsine. Some maintain that it is inert, as it often is, no doubt, through fraud or bad manipulation. Others, again, attach the importance to it which might be expected from reasoning on well known physiological facts, and find their *à priori* conclusions supported by experience. The difference of opinion is due, in this case, to the difference in the quantity of pepsine present in an active state in the preparations used; and this must arise from some defect in the *modus operandi* of procuring it.

I will not here enter into any critique on the ordinary processes; a fair sample of pepsine may, with care, be obtained by most of those published, though erroneous statements have obtained currency as to the effect of various reagents on it. What is desirable is, that some convenient and certain process be discovered with definite results easily tested.

With these objects in view, I commenced my experiments, and with the result of procuring a solution of pepsine definite and certain in strength, and so pleasant to the taste that even children will not find it objectionable, but the contrary.

The fresh stomach of the pig having been washed in water sufficiently to remove all particles of food, and the cardiac end removed as yielding rennet only, is cut into slips and digested for one week in as much glycerine as will entirely cover it, then strained and filtered. The resulting fluid is about the consistence of simple syrup, somewhat thinner than glycerine, of a pale sherry colour, sweet to the taste, with the characteristic flavour of pepsine.

A drachm of this, with 15 minims of muriatic acid, and an ounce of water added, at 100° readily dissolved 700 grains of moist fibrine properly prepared; while the best of the solutions in general use, which I have tried, only dissolved 75 grains, and that not so completely under the same conditions.

Lactic acid, which is generally stated to answer as well as muriatic, I have found comparatively inert, which tends to corroborate the original opinion of Prout in opposition to the statements of M. Bernard and Barreswill.

The solution I have described has this further recommendation, that whereas the various solutions of pepsine in sherry, &c., are very liable to spoil, this keeps very well. I have before me now some of it made seven months ago, in which there is no sign of decomposition.

Half a drachm to a drachm taken in a little water at, or immediately after, meals ought to be found the most effective preparation of pepsine in use. It may be taken undiluted if preferred, but should be always associated with food in the stomach. It is quite compatible with most articles of food in ordinary use which are really wholesome and digestible; but it would be well to bear in mind that alcohol, unless very dilute, destroys pepsine, whether it be the natural exudation from the gastric mucous membrane, or that introduced as a supplement by modern science. The cases in which it will be found applicable, I leave to the physician, as it would be foreign to the purport of this paper to describe them.

As the action of any agent derived from the animal kingdom is an unknown quantity in calculating effects, its adoption, therapeutically, should be with discretion; I have, therefore, thought it right, considering the powerfully solvent or digestive action of this solution, to test it in my own person before recommending it to others; and I can testify, for the confidence of my medical friends, that it is not only quite safe, but, so far as one can estimate in a limited experience, beneficial in the degree to be expected *à priori*.

To prevent confusion, and at the same time to invite

trial, I have called my solution "Prepared Gastric Juice," or "Digestive Solution of Pepsine," a small bottle of which I shall be happy to send to any medical man disposed to try it—not with a view to elicit claptrap testimonials on narrow premises, but to enable them to judge of the value of this remedy in some of the most troublesome cases which come under the care of the physician.

Let it once be granted that pepsine removed from under the action of the vital force retains its activity, and it follows that simplicity and certainty in the process for obtaining it in such a form as will keep reasonably well, are all that is required. Both desiderata, I believe, I have arrived at, judging by the tests already mentioned, and I now with confidence offer the result to the profession.

As a postscript it may not be unnecessary to remind, that pepsine and rennet are quite different things, and produce different effects; one of the most obvious is, that the latter coagulates albumen, while the former dissolves the curd so formed. It has frequently come to my knowledge that people have been directed by their medical attendants to make whey with pepsine wine, and are not a little disappointed to find that they cannot succeed, rennet wine or essence no doubt being intended.

NOTES ON SOME CASES OF ERYSIPELAS.

By JOHN W. MARTIN, M.D., M.Ch.

In the following remarks, I wish merely to record the observation of a few points which, I think, are possessed of some interest.

During the last eight months, three well-marked cases of erysipelas of the head and face have come under my notice, the subjects being all persons in the poorer ranks of life, two of them women, and one a young man.

CASE 1.—Mary K., æt. forty-five, wife of a labourer; the attack commencing six weeks subsequent to her confinement.

CASE 2.—Mary M., æt. thirty-five, wife of a factory operative, and mother of nine children. Has always been delicate, and during the three months preceding the attack had to give up work.

CASE 3.—Maurice D., æt. twenty-two, factory operative; unmarried.

In all the form of attack was phlyctenoid; there was a period of *latency* for a week before the appearance of the eruption, as marked by languor and a general feeling of "malaise," and the attack itself set in with the usual symptoms of nausea vomiting, pain in the back, loaded tongue, quick pulse, and confined bowels. In all, the glandulæ concatenatæ were painfully swollen and tender, accompanied by a feeling of stiffness in the neck.

The most careful inquiry into the cases of the two women could elicit *no history of lesion of any kind* from whence the attack might have had its starting point, thus forming exceptions to what Trousseau, in his excellent chapter on erysipelas, states to be almost universally the rule.

In the case of Maurice D., there was sore throat accompanying, but not, as far as I could learn, preceding the attack; but there was *no lesion* in the neighbourhood of the brow, eye, cheek, or ear, where the blush first exhibited itself.

In each of the cases the climax, as shown by thermometrical observations, was reached at periods varying from the sixth to the eighth day, the highest temperature varying from 101 one-fifth degs., to 101 three-fifth degs.

In all, at the point where convalescence was becoming thoroughly established, there was a fall in the temperature several degrees below normal, varying from 94 one-fifth degs., to 97 four-fifth degs., the most careful observations being made to establish these temperatures.

A similar fall in temperature, before the establishment of convalescence in febrile disease, has been observed and recorded in some thermometrical observations made by my

father during an epidemic of typhus fever that occurred in Portlaw in the winter of 1866, and the spring and summer of 1867.

In all chemical examination of the urine showed the presence of sugar; in the case of Mary M., the test for uric acid was followed immediately by a copious precipitate, its presence being confirmed by the microscope. I am sorry to add I omitted this test in the other two cases.

The treatment in all cases consisted in dusting the part affected well with flour, the exhibition of mild aperient medicine, of muriate tr. of iron and wine ζ iv. daily, the patient being given as generous a diet as possible.

The points of interest seem to me to be—

1st. Is there a true period of latency culminating in the febrile symptoms usually preceding the eruption? or, are the febrile symptoms dependent on the engorgement, tenderness, and accompanying constitutional disturbance set up in the neighbouring glands, by the presence of a lesion of some kind or other, from whence, according to Trousseau, the eruption takes its starting point?

2nd. Is there in all febrile diseases, as a rule, a fall in temperature below normal before convalescence is established?

3rd. Is sugar usually present in the urine of erysipal-tous cases?

Hospital Reports.

ROYAL VICTORIA HOSPITAL, NETLEY.

CASES OF ANEURISM.

WE have already given two cases of thoracic aneurism from the Report of Dr. Maclean, and now proceed to add the following. The learned Professor remarks, in connection with these cases, that the statements of soldiers as to a syphilitic history must not be implicitly relied upon. He has often known it stated that there was "no syphilitic history," when the autopsy has revealed unequivocal evidence of such lesions.

In Dr. Davidson's paper, the connection between atheromatous degenerations and syphilis are well shown, and the Pathological Museum at Netley affords abundant evidence of the fact. In the specimens of aneurisms of large vessels, organic lesions of their walls induced by syphilis are almost always met with.

Aneurism of Thoracic Aorta, causing a Tumour under left Scapula; Rupture of Intercostal Spaces between second and third, third and fourth, and fourth and fifth Ribs, with Dislocation of the fifth and Destruction of the Articular Surfaces of the third, fourth, fifth, and sixth Ribs; Death from Hæmorrhage.

Gunner C. Armstrong, aged twenty-seven, from Gibraltar, admitted 9th July, 1866; died, 28th July, 1868.

Syphilitic History.—This patient belonged to a garrison battery, and was in the habit of working heavy pieces of ordnance; was repeatedly in hospital at Gibraltar, complaining of "pain in his chest, occasional attacks of dyspnoea, and cough." He also suffered there from rheumatism, continued fever, bronchitis, primary syphilis, and cholera. On the last occasion of his being in hospital at Gibraltar, on the 19th of April, 1866, he was in bed, when he suddenly became conscious of "something giving way under the left shoulder-blade, attended with a hot rush of something in the same place." He became faint, but on recovering a little called for assistance; when the orderly came he discovered "a swelling under his shoulder-blade, which was beating."

State on Admission.—A large pulsating tumour projected from under the left scapula, displacing it outwards; this pulsated strongly, and expanded equally in all directions, with pain, sometimes very violent, in the chest, shoulder, and spine, requiring frequent subcutaneous injections of morphia to allay it.

The tumour went on enlarging till the 2nd of July, when he became weak and pale, with an intermittent pulse, and died very gradually on the 28th.

Post-mortem Examination.—*Thorax:* Adhesions of old standing on both sides; left side of chest contained 25 ozs. of blood, part fluid, part in clots, which had proceeded from a large aneurism of the aorta.

Aorta.—Much diseased; its inner surface was thickly studded with cicatricial-like contractions.

There was a large aneurism of the ascending thoracic aorta, which extended from the third dorsal vertebra, which was deeply eroded, to the lower margin of the sixth rib, three inches from its attachment to the spine. The long diameter of the sac was directed backwards in the direction of the scapula. The rent from which the hæmorrhage proceeded was an aperture large enough to admit two fingers, situated in the depending part of the sac, on a level with the intercostal space, below the margin of the fifth rib. The intercostal space between the first and second ribs was intact, but in the space between the second and third, third and fourth, and fourth and fifth ribs, the finger could be passed through large openings into a sac as large as a child's head, situated between the ribs and the scapula. This sac was filled with large clots, constituting the pulsating tumour observed during life. The third, fourth, fifth, and sixth ribs were deeply eroded for about three inches from their heads; the fifth was completely dislocated, and so dissected from the soft tissues that it was pulled out from its position without any of the soft parts adhering to it. The sixth rib was also partially dislocated.

Doubtless the "tearing sensation" and "hot rush" described by the patient were due to the giving way of the intercostal muscles, and the passage of blood between the ribs and scapula.

The intercostal muscles subjected to the pressure of the tumour had undergone the yellow degeneration usually observed under such circumstances.

The patient survived the outward formation of the tumour three months.

Aneurism of Abdominal Aorta; Distinct Syphilitic History; Death from gradual Hæmorrhage.

Private John Smith, 88th Regiment, age twenty-nine. Date of admission, 7th May, 1866; died, 18th December, 1866.

Invalided from India for aneurism of abdominal aorta. On admission, a pulsating tumour was found on the left side of the abdomen, near the umbilicus. When first observed it was the size of an orange, and had pushed its way upwards, inclining to the right. Afterwards it seemed to recede, and to press backwards, causing great pain of an intermitting character. From first the arterial nature of the tumour was well marked, the symptoms being impulse, corresponding with heart's action. Bruit distinct and constant; pain throbbing and at times plainly neuralgic, and very agonising, requiring the frequent use of the subcutaneous injection of morphia to make life endurable. The pain, limited to the abdomen, did not extend to the lower extremities.

Became gradually weaker, and died apparently more worn out by his sufferings than from hæmorrhage, which, however, had taken place gradually.

In this case there was no erosion of the vertebræ: the extreme pain from which the patient suffered was due to the stretching of nerve filaments across the sac.

Pleura.—Several pleural adhesions on both sides, and 24 ozs. of dark-coloured fluid were measured out of the thorax.

Lungs very anæmic; tubercular deposit in apex of left lung.

Heart normal.

Aorta much diseased; inner surface puckered, with cicatricial loss of substance.

Abdomen.—A thin clot of blood was found on the anterior surface of the stomach and omentum, and several

large clots in the cavity. A large aneurism of the aorta was found taking its rise just where the vessel enters the abdomen. The sac was partly covered by the crura of the diaphragm, and was the size of a large cocoa-nut. A small rent was found on its posterior surface, the source of the hæmorrhage.

Dr. Maclean remarks that—

“It is not necessary to multiply examples; they are all very much alike. The morbid appearances in the above cases correspond closely with most of the older ones preserved in the Pathological Museum here. Both bear evidence to the fact that vessels undergoing degeneration, the root of which is certainly to be found in the syphilitic dyscrasia, cannot withstand the force of the circulation to which they are subjected in military life by the faulty system of dress and accoutrements so long in use.”

THE INTERNATIONAL MEDICAL CONGRESS AT FLORENCE.

(FROM OUR SPECIAL CORRESPONDENT.)

THE Medical Congress met on the 23rd instead of the 20th September, as a meeting of medical men and scientific people was still going on at Innsbruck on the 20th. To repay for the loss of time, it was settled that every day two sittings should be held—one, according to the questions of the programme, in the morning, and a second in the afternoon, upon free subjects. It would be impossible, and perhaps useless, to report all the details of those sittings, but I suppose that it may prove interesting to English physicians to hear something concerning the most important subjects which were discussed during the session.

The first subject, and which, as the most interesting, occupied four full morning sittings, was the one of the marsh-miasma, its origin, its nature, and what are the best means to destroy, or at least to counteract it. Dr. Pantaleoni, who first treated generally the subject, and others like Dr. Umara, Dr. Spaturri, Dr. Mingrona, gave details about the miasma of Sardinia, of the valley of the Liris, and of the Brutian countries. It is really admirable the accord existing amongst Italian physicians about the laws which rule the development of the palustrian miasma. They all agree on the laws promulgated by Dr. Pantaleoni, that the miasma rises not only from marshes, but also from land newly excavated; that it does not rise very high from the surface of the ground, but it may be carried by winds to a great distance, and so infect distant villages and towns more than those which, sheltered from the wind, lay near the marsh itself. They all agree that an amount of heat, mixed chiefly with dampness, is necessary for the creation and development of the miasma, which otherwise is nowhere to be found; but where are vegetables is putrefaction; cryptogams in formation, either from the fungous deposits of the marsh, or by stagnant waters on newly excavated earth. So Dr. Pantaleoni concluded that the palustrian miasma is of a vegetable origin, almost as surely as the one of typhus and typhoid is of an animal origin, and therefore two quite different sets of fever, the last generally catching, and the others completely deprived of the contagious or infectious nature. Dr. Pantaleoni went even further, proposing, as a most probable hypothesis, that the miasma should be considered as a real plant, a kind of *alga*, whose spores, carried in the air, should produce the affection. He had determined to undertake some experiments upon the subject in the Pontine marshes, and had invited Dr. Balestra, of Rome, to help him. However, Dr. Balestra had on his own account entered on the same line of most interesting experiments, by which he has shown that the fog and the air of marshes is infested with myriads of spores from an *alga* peculiar to the marshes, and which he named *febrigenica*, and Dr. Pantaleoni *pyretojenica*; that the influence is in proportion to the development of those

spores; that inhaling those, or drinking it in water, the ague is almost always produced; and that the application of a solution of quinine kills those *algæ* in twelve to twenty hours; an arsenical solution is less active, and the sulphites even less. The infusoria or animalculæ exist in the transported air, although they exist in the fog of the marshes.

These particulars separate immediately Dr. Balestra's (of Rome) experiments from those of Dr. Salisbury of the United States, as this last saw animals and spores. He attributed the affection to a *palmetta*, which is demonstrated to be impossible, and then never saw quinine acting upon it. Dr. Balestra's observations confirmed so well the proposition of Dr. Pantaleoni, that a vote of the Congress was presented, to state that the existence of those cryptogams as a cause of miasma was a real discovery; but Dr. P. himself opposed it on the ground that the experiments and observations were not numerous enough; that many other points remained to be cleared, as the way by which those spores acted, if locally or entering in the blood, where it was necessary to ascertain their presence to fix the doctrine as a fact. The Congress deferred willingly to these remarks, and it was proposed that new studies should be brought to a future Congress.

But another important point was maintained by Dr. Pantaleoni in his communication, and that is, that not only *agues*, but very frequently a *remittent continuous fever*, is produced by slow imbibition of the miasma, and that the nervous fever of Rome, the putrid so-called, belongs almost always to this class. He gave all the characters and differences of this fever in distinction from typhoid, as he had already done in the Congress at Paris, and demonstrated its connection with the miasma. Several other Roman physicians also read communications upon the *remittent*, concurring in Dr. Pantaleoni's ideas; but there are other physicians who do not still admit of it.

It was also remarkable how all the Italian physicians agreed in the idea that the chief cause of the fevers and malaria had been the neglect of agriculture, leading to the destruction of the population, and they advocated a return to the old state as the best means of counteracting the malaria. Dr. P. chiefly insisted upon the dangers of adopting the system of great drainage, at least without having previously by large plantations counteracted the increased development of the miasma; and he at the end expressed the hope that perhaps some chemical means may be found of impeding the vegetation of the mortiferous *algæ*.

Only one person, Dr. Salvagnoli, differed from the others. He advocated again an ancient Tuscan doctrine, that the malaria was originated from the mixture of salt or sea water with river or marsh water, and therefore he thought that large brooks may prove useful. Dr. Pantaleoni demonstrated the inconsistency of this doctrine with facts—1st. Salt water mixes necessarily everywhere with river water at the mouth of those; in those countries where the tide is strong, sea water comes up for several miles on the river, mixing the two waters, and no malaria is ever originated from that circumstance. 2nd. Marshes exist at Verona, at Mantua, in Hungary, on the Ohio, and in India, at immense distances from the sea, and where there is no possibility of the mixture of the two waters. 3rd. In all those facts quoted by Dr. Salvagnoli, as in the estuary of Venice, or the cataracts constructed with such an advantage in Tuscany, it is the mud carried by rivers, and full of vegetable substance which has been excluded, or through those valves it has been checked the repulsive action that the sea exercises everywhere upon the rivers, throwing difficulties to the free discharging of the matter carried with the waters on the sea. Dr. P. advocated again the vegetable nature of the miasma, which is admitted by almost all the present physicians.

Few things were added about treatment, as too obvious to any physician and practitioner.

Another subject might interest English physicians. It

is the introduction of *marine hospitals* for scrofulous and lymphatic cases. A Dr. Barcellai, by no means a man of any great intellectual distinction, but endowed with the most benevolent instincts and great perseverance, has proceeded to introduce into Italy a great number of those establishments at the sea-shore, where in summer, through the help of the municipalities and public charities, a great number of cases, chiefly of children, are yearly sent for baths, air, sun, and good food, with a very great profit to public health. Dr. Barcellai read a paper giving an account of these establishments, which was loudly applauded.

The question of the treatment of cancer, or cancerous tumours, through hypodermic injections, was brought by the programme before the Congress. Dr. Lofrana brought in this system of obtaining disintegration through the injection of gastric juice in the tumour; but, honestly, he remarked how different were the effects in different attempts made by him (Dr. Lofrana) in different cases. Prof. Lebrief, a Professor of Physiology, invited to a particular sitting upon the subject, and those with a superior science and multifarious experiments, demonstrated how difficult it is to get real gastric juice, excepting if they have followed so many precautions as he demonstrated indispensable to get it, and always active. However, Dr. Lebrief disapproved of the use of the gastric juice, showing how terribly dangerous its use would be if it penetrated inside one of the sanguineous vessels, as gastric juice acts upon fibrinous as well as albuminous tissue. Introduced into a vessel, gastric juice produces thrombosis and death almost always in animals. Dr. Lebrief, instead of the gastric juice, strongly advocated the use of pancreatic juice injections, as this liquor does not affect fibrine and the vessels, but only discloses the albuminous deposits of the scirrhus, cancerous, and canceroid tumours. The learned Professor, with numerous experiments, demonstrated the best way of getting good pancreatic juice, which, however, he could not himself get pure and active for a very long time.

Dr. Pantaleoni read a communication upon Dr. Chapman's spinal ice bags, and their application to several cases of vomiting, chiefly those obstinate vomitings that sometimes appear, almost rebellious to any treatment, from an irritation of the *unimpregnated* womb. He quoted several cases of success, and chiefly one which had been the puzzle and the despair of all the physicians who had before attended it. He then spoke of several other applications of those bags against neuralgias, giving a beautiful but obstinate case of lateral abdominal neuralgia where the cure had been complete. Dr. Pantaleoni quoted four cases recently published by Dr. Chapman. The communication was eagerly received, as it was quite new for all the physicians present. All wished to try it; Dr. Chapman ought to provide an agency for the sale of his bags somewhere in Italy.

Dr. Pantaleoni gave a notice of Dr. Cruise's endoscope, or rather of Dr. Cruise's improvements to the one of Deformeaux, and quoted many cases of its application, and also to the internal cavity of the womb. The instrument was unknown, very much admired, and the general wish was to have a depot of such an instrument in Italy.

Dr. Laravewitch, from Russia, presented an embriotome, really very useful, and a complete set of obstetrical instruments, which are a practical improvement upon the existing ones.

Dr. Tassi, of Rome, communicated the report of his practice amongst men employed on the railway, and he presented an interesting work upon it.

Dr. Routh sent a communication upon the mortality amongst children in England, which was considered a very interesting one.

Dr. Lombard, at Geneva, gave maps of mortality upon the earth, tracing with different colours the season when the mortality was the highest in each point of the globe,

and also the countries where the mortality was the greatest.

Dr. Pantaleoni, in a second lecture, spoke of the essential fevers, returned to the existence, character, extension, and treatment of the miasmatic remittent, and took the occasion of entering upon the subject of military fever. English physicians do not, perhaps, know that the Tuscan and Piedmontese physicians, and the first chiefly, speak almost of nothing but military and military fever, to which they attribute all the possible symptoms and all the mortality of Tuscany. Dr. Pantaleoni, with multifarious reasons and facts, denied the very existence of such a disease, except as an unimportant exanthematous eruption, or as an epiphenomenal sign of another fever. He demonstrated how frequently in France, in England, and everywhere, military eruptions accompanied typhoid and typhous fever without certainly constituting the essence of the disease; how frequently they were to be seen even in small-pox, in scarlet fever, and measles only as a symptomatic occurrence; and he concluded that all the cases of military which he had met in four years in Italy were cases of remittent fevers, not, as considered by the Tuscan school, cases of zymotic diseases accompanied with military eruption. He saw only one case of essential military eruption, but it was accompanied with a slight fever, just as it might be in a case of urticaria or nettle-rash.

Such an attack, although delivered in the kindest and most eulogistic terms for the Tuscan profession, could but excite an uproar amongst some and plaudits amongst the Neapolitans and foreign physicians who partook of Dr. Pantaleoni's views on the subject. Professor Ghinozzi gave a long speech next day in answer to Dr. Pantaleoni; but the defect of this doctrine remained always the same. No precision of description, no pathognomonic symptoms or signs, uncertainty in diagnosis in prognosis in treatment—an indefinite state of it from head to foot. The fact is, that the miliarists make a complete confusion of essential and of symptomatic or epiphenomenal military eruption, and, such being the case, it is impossible that they could ever come to a practical conclusion upon it.

Dr. Baccelli, of Rome, presented a pleximeter of his invention, to which, however, he attributed those exaggerated praises which usually all inventors of instruments do. Dr. Baccelli read also a paper upon pernicious fevers, and tried to develop a doctrine about an abdominal circulation between spleen, liver, and stomach, which, however, was strenuously contradicted by Dr. Sterzen and Dr. Schief, with such an overwhelming accumulation of experiments and of proofs against it, that there was no possible answer in its defence, although Dr. Baccelli, a physician certainly endowed with much talent, tried his best to defend his conclusions.

Another very important subject was treated: the comparative advantages of hospital treatment, or of *séours à domicile*. Dr. Bouillaud rose in favour of the hospitals, chiefly on the score of public instruction. Dr. Pantaleoni, and more extensively Dr. Seitz, of Munich, spoke in favour of adding to the indispensable existence of the hospitals and of the hospital instruction the instruction of the policlinic schools as introduced in Germany, and as much as possible in our social and political state, the distribution of medical treatment and medicines in private houses or at least in barracks, opened as much as conveniently to the air. The statistics quoted by Dr. Seitz about the comparative result of the two systems leave no room for doubt when and where the second system can be employed.

The Congress was closed the 2nd of October. The kindness and the benevolence shown by the Tuscan physicians to their colleagues are beyond all praise. Without exception, thanks are due to Professor Brugnoli, Dr. Bos, Professor De Marian, Professor De Renzio, Professor Palasciano, Dr. Pantaleoni, and all the committee and well-wishers of the Congress.

The next International Medical Congress was fixed for 1871, at Vienna.

SPECIAL REPORT

ON

STUDENTS' TEXT BOOKS.

(Prepared expressly for the MEDICAL PRESS AND CIRCULAR,
by Professors in Schools of Medicine.)

No. III.

WE have not yet disposed of the earlier subjects of the student's course, and must, therefore, recur to them. We last spoke of Physiology, and on this important subject should say that for those who aim at that extensive knowledge required for high honours, Carpenter's "Principles of Human Physiology" (Churchills) is the book that most English students will find suited for their purpose. Carpenter's "Manual," one of the often-praised series of the same publishers, is more adapted for earlier use, and we have already said that Kirkes's "Manual" is a very good one.

We would next introduce, to those who do not know it, the "Manual" of Dr. Mapother, published by Messrs. Fannin. Dr. Mapother's experience as a teacher has enabled him to supply a work which has many attractions for the student. It is one of the most concise text-books of Physiology and pathology; is entitled "A Manual of Physiology and of the Principles of Disease" (Fannin, Dublin; Longmans, London; Maclachlan and Stewart, Edinburgh), is illustrated by 150 engravings, and moreover, contains more than 1000 questions on the subjects upon which it treats, selected from such as have been asked at the various Examining Boards. This shows what a good idea Dr. Mapother has of a student's work, and we can say that it is well carried out. We have looked through this manual for the purpose of this Report with much pleasure, and have been frequently struck with the author's way of making a subject easy. We, therefore, strongly recommend it to all who look for a small text-book on Physiology; and it is also, perhaps, the best for non-medical readers, who desire to acquire some knowledge of the laws of health and disease.

Another attraction to it is a copious glossarial index, which cannot fail to be of service to younger students. The book abounds in information, and the questions on each chapter enable the student to test his progress in assimilating it as he goes on.

Dr. Mapother opens his Manual with a brief sketch of cell life and the properties of tissues. Then comes a section on the natural history of man, followed by one on his chemistry. Digestion, absorption, the blood, the circulation, respiration and animal heat, secretion, innervation, motion, voice and speech, the special senses, and reproduction, are the successive sections. This completes the larger and more important part of the book. The second part, devoted to the physiological changes in disease, is of great interest, will enable the student to connect his physiological studies more immediately with the practice of medicine, in fact furnishes him with a concise and clear sketch of the subject of General Pathology. It is a fit introduction to the large works on Pathology, which mark the labours of the few who have devoted themselves to its elucidation.

A few examination papers of the London University, the Queen's University, the Royal College of Surgeons, and the Army Medical Department, are then added. The student would find it a very useful process, after he has

carefully gone through the Manual, to sit down at times and write replies to them.

Turning again to Anatomy, we have to announce that the new editions we mentioned as about to appear of Heath, Holden, and Gray, are now ready, and quite fulfil the anticipations we expressed. Holden's "Osteology" (Churchills) has been thoroughly revised by the author. The lithographs have been redrawn, as the stones were wearing out, and their accuracy and artistic excellence are as surprising as ever. The work is without a rival, and we would urge every student to buy and study it. Gray, the favourite reading volume of London students, comes before us with a special addition of the utmost importance, in form of an introduction on general anatomy and development by the new editor, who is no other than Mr. T. Holmes, of St. George's Hospital. As a surgeon and a teacher of Anatomy, Mr. Holmes is too well known for anything coming from his pen to require commendation. The fact that the new edition has been revised by him is sufficient guarantee that it has been brought down to the present day. This work will suffice for the examinations for honours in Anatomy. Gray's "Anatomy, Descriptive and Surgical" (Longman's), in this, the fifth edition, will maintain its position as a favourite book, and we should hope that every one who employs it will take care to master the new introduction of Mr. Holmes.

Heath's "Practical Anatomy," second edition, is one of the smallest of Churchill's series. It professes to be "a Manual of Dissections," and must, therefore, be judged as such. We prefer it much to Ellis, which is too tedious. The engravings, 278 in number, are of the very best kind, and the work throughout is concisely and clearly written. In this department we have yet two very valuable books to speak of—both emanations from the Dublin School, both favourites there, both strongly bound, with cut edges—one illustrated, the other not. One, the "Dublin Dissector," known wherever the English language is employed in the dissecting-room, and of which ten thousand copies have been sold; the other, Ledwich's manual, These we must notice in our next.

Comparative Anatomy and Physiology occupy a place at some of the Examining Boards, and every medical student should be making himself to some extent acquainted with it, as he will thereby increase his interest in the work, and, on account of the broader foundation he lays, building upon it will be safer. A very brief outline of the subject, in fact a sketch of the essentials, and the essentials only, constitute a pocket volume entitled "Manual of Comparative Anatomy and Physiology," by Mr. Messenger Bradley, F.R.C.S., Professor at Stonyhurst College, and at the Manchester Royal School of Medicine. It is published by Cornish, of Manchester, and Simpkins, Marshall, and Co., London, and we are glad to introduce such an outline by a member of our Profession and a teacher. It will serve as a first book for the general reader, or as a syllabus for those attending lectures.

Really, brevity is in these days a great merit, and those who are not obliged to work at this subject will be surely pleased to get a syllabus of it which they can readily understand, and which could always be carried in the waistcoat pocket. We beg to suggest to the publisher that a few copies, interleaved for notes, might possibly find a sale.

The intimate connection between Anatomy and Surgery is well illustrated by the success of books on Surgical

Anatomy. The magnificent illustrations of Maclise deserve mention, though their expense is considerable, so that they are almost out of the range of students' text-books, though excellent furniture for the surgeon's library.

"The Anatomy of the Arteries of the Human Body, Descriptive and Surgical, with the Descriptive Anatomy of the Heart," by John Hatch Power, M.D., Professor to the Royal College of Surgeons in Ireland; with illustrations by B. Wills Richardson, F.R.C.S., and Examiner to the same College; is a text-book of the first class, and one that supplies just what the student most wants in this department of practical work. It is a small, neatly-printed, almost pocket-volume, with cut edges and good binding—useful at home to recall dissections, as well as in presence of the subject to compare and consider. It is published at a low price by Messrs. Fannin.

We pass now to a consideration of the great practical work of the student. Not that he can be perfect in Chemistry, Anatomy, and Physiology, before he proceeds to the study of the art of Healing; for, even if that were advisable, it is impossible, on account of his curriculum being laid down for him. From the first, Surgery is made imperative, and he must therefore study it conjointly with the other subjects we have gone over in his first session.

The Manual *par excellence* is Druitt's, and every student must therefore buy that first. That is his text-book for his first year. Two or three little books on minor surgery are good in their way, especially for those who see general practice before entering at a hospital; but, as soon as surgical practice in the wards begins, Druitt's is the true "Vade Mecum." For home reading as relaxation, there are many excellent books, both new and old. Industrious men cannot fail to be pleased and instructed by works now out of date, such as Samuel Cooper's "First Lines," Bransby Cooper's "Lectures," Brodie's works, and others; but all these should be corrected to date by reference to Druitt. The works of Syme, Miller, and Pirrie, must also be named as those of great teachers. Dr. Spence has commenced a work on the subject, of which only one part has yet appeared. The student who would like to have some of the elder authors named will be able to buy them second-hand at a low price. London students, too, will find that Mr. Lewis, of Gower street, not only has a stock of these, but a lending library, where, for a moderate subscription, they can read such as they cannot afford or do not wish to purchase.

In Practical Surgery Sir William Fergusson's "Manual" occupies the front rank.

Advanced students and those reading for F.R.C.S., or for University honours in Surgery, should take seriously in hand a work that will be useful to all surgeons, and represents the present state of the theory and practice of Surgery with exactitude and fulness combined. We allude to "Holmes's System of Surgery" (Longmans), of which a new edition, with engravings and chromolithographs, is now in course of publication. Volume first is just out, and we shall examine it at length. There are to be four others. The work is not the sole production of Mr. Holmes, but of a number of the foremost surgeons of the day, who have written monographs, each on the subject with which he is most familiar, all of which have been brought together under Mr. Holmes's able editorship. It is, therefore, somewhat similar to Reynolds's "System of Medicine," an equally meritorious work. In recommending the "System of Surgery" to advanced

students, we are aware that it is an expensive work; but then it is a purchase for a lifetime,—nor need it all be bought at once.

The first volume, just out, comprises the whole of General Pathology. The student who masters it need fear no examiner, and may anticipate taking high honours. He who buys Holmes's "System" buys a surgical library of great value.

(To be continued.)

EXTERN MATERNITIES AND LYING-IN HOSPITALS.

A REPLY TO CRITICISMS ON A COMMUNICATION TO THE DUBLIN OBSTETRICAL SOCIETY.

By EVORY KENNEDY, M.D., F.K.Q.C.P.

(Continued from page 295.)

THIS general sentence of death, pronounced by Dr. Stokes upon all cases of puerperal fever, evidently astounded the Society, and called for a pointed inquiry from Dr. Murney. I can, therefore, quite understand why Dr. Stokes should have *felt himself* justified in pronouncing a greater mortality in degree, as all *his* cases in private practice were fatal; and greater than this there could not be, and possibly even as *far as his own experience went*, a greater mortality in quantity, as he does not tell us whether he even attended cases of it in hospital. But the general tenor of his conclusions would lead to a contrary conclusion. Therefore it is quite possible that he might have been justified in drawing the same conclusions from his own experience in quantity also. But it remains for the Society to be satisfied or otherwise with this conclusion, more especially when they recollect the annual statistics of mortality for 111 years, the detail of which they have had to submit to as administered at my hands, and Dr. McClinton's honest admission of the great mortality in lying-in hospitals.

I therefore submit that if Dr. Stokes has no stronger grounds for refusing his assent to the greater proportional mortality in lying-in hospitals from puerperal fever than the result of his own practice with his reasoning upon it, that I am justified in pronouncing that he has arrived at an impotent conclusion.

I shall not, however, be so ungenerous as to withhold from the Society a fact with which, as our object should be more to arrive at truth than victory, it should be acquainted—namely, that Dr. Stokes does not stand alone in his convictions of the mortality of puerperal fever generally. Sir Charles Mansfield Clarke, whose experience as an obstetric physician was very great, has uttered the same opinion.

Dr. Joseph Clarke writes in March, 1829:—"In looking over the *Medico-Chirurgical Review* for January, 1829, my attention has been excited by a paper entitled, 'Rapidly Fatal Puerperal Peritonitis. Atmospheric Constitution of 1825-6-7 8. By Dr. Farrel.' Here it is stated, on authority, I presume, not to be doubted, that one practitioner in London lost 7 patients in a few weeks, and another 4 within one month, all by similar diseases; and that one consulting practitioner saw 13 cases, 11 of which died. In hospital practice," continues Dr. J. Clarke, "such events do occasionally occur; but in this city (Dublin), I can speak confidently, since the year 1781 they are unknown to us among the upper ranks of society." Sir Charles Mansfield Clarke, in his answer, March 10, 1829, writes:—"But I should not say that my own experience in consultation cases agrees with the statement to which you allude as to the mortality amongst lying-in women in London during the last four years; but as I believe one form of peritonitis is infectious, and as this form admits little in the way

of remedy, several such cases may occur in the practice of one man, whilst another in the same district may be entirely exempt from them. Many examples of this kind have come within my knowledge. I wish it were in my power to say that I knew anything about the run of this disease; but every year's experience convinces me of the intractable nature of this complaint, and of the entire inadequacy of any mode of treatment with which I am acquainted in curing it. I do not here speak of a pure acute peritonitis, but of that disorder of which we spoke together when I had the pleasure of meeting you in London."

I have been induced to give these extracts from the correspondence of these great obstetric physicians, not merely as elucidating Sir Charles M. Clarke's views of the fatality of what he considered the true puerperal fever, but from their bearing upon questions of contagion, as well as from Dr. Joseph Clarke's views of the hospital being its habitat, and its spread in private practice evidently having been there traced to contagion not epidemic influences. But the really valuable part of the correspondence, and that to which I wish especially to draw the attention of the Society, is, the statement of Dr. Joseph Clarke, who was as well the ablest obstetrical physician of his day, or perhaps of any day, and the physician of the largest consultation practice for nearly sixty years in Dublin, "that between the years 1781 and 1829 he could speak confidently they (puerperal fever cases) are unknown to us among the upper classes of society, although in hospital practice such cases do occasionally occur."

Dr. Stokes asks—"Is simple pregnancy the cause or the source of the development of a malignant poison? Who would believe that?" And continues—"The condition of a parturient woman had been compared to that of a person after a surgical operation. The analogy is by no means perfect." In the one case he says—"The patient is the subject of a natural process, a process which the Almighty intended to be perfectly consistent with health and with life. In the other case, the patient, who is subjected to a great surgical operation, is the subject of an entirely different process. The analogy is good in a mechanical, but it certainly fails in a physiological point of view."

Now, that there is malignant poison developed in pregnant females evidence has been adduced over and over in the course of this discussion, and that it is malignant, Dr. Stokes's recorded opinion of the invariable fatality of puerperal fever is the best proof. That pregnancy, or more properly, parturition, is the cause or the source of it is evident from its being a disease "*sui generis*" only to be met with in pregnant women. As to the analogy between parturition and a surgical operation, denied by Dr. Stokes, I cannot conceive any two processes, not identical, between which a fairer or a stronger analogy could be drawn. The reception which this analogy has met from every speaker in this debate who has alluded to traumatic metria, is remarkable.

Dr. Stokes's denial of this analogy, and his insisting upon labour being "a natural process which the Almighty intended to be perfectly consistent with health and life," is strangely at variance with our finding this eminent and philanthropic physician in the ranks of those who deny the necessity of effecting changes in our great hospitals, which are calculated and directed towards lessening a death-rate occurring in them "amongst those subjects of a natural process, a process which the Almighty intended to be perfectly consistent with health and life," in the proportion of one out of every thirty-one delivered. Surely if it be a natural process, one out of thirty-one should not die in it; and if such a mortality occur, in what Dr. Stokes denominates and takes so much trouble to prove is a natural process, then it is his duty to detect the cause of this great mortality in a natural process intended by the Almighty to be consistent with life and health, and to

remedy it in the manner that experience has already proved it can alone be done.

Had Dr. Stokes ever once witnessed a labour which, unfortunately for the cause of the parturient now at issue, he says he has not, I doubt not he would have detected the analogue he denies, and changed his mind upon the true nature of the process of labour. He would have then felt the full force of those words—"in sorrow and anguish shall thou bring forth"—which appear to have escaped his recollection in reasoning out this question. He would have borne in mind that labours are divided in our school-books into natural, preternatural, and tedious. He would have had before him the fact that in the most rapid cases it is often the most dangerous; whilst in the tedious cases it is unendurable. That the shock, *physiologically* speaking, inflicted upon the female constitution is quite as great as that produced by a capital operation, whilst the amount of pain is infinitely greater. Again, the delay in the suffering and the amount of pain is such that, were it to continue uninterrupted, and without the intervals of freedom, no female could survive it. If he will add to all this that, in a very considerable proportion of cases, where manual interference is had recourse to—when the labour is too rapid or very tedious—lesions of a serious, sometimes of necessarily fatal nature occur. Had he, in fact, witnessed one labour, I doubt not he would have changed his mind upon the perfectly natural process he makes so light of, as well as of the intentions of the Deity in regard to it.

Dr. Stokes, on the authority of a friend, drew the attention of the Society to a very remarkable fact. Puerperal fever is the endemic fever of Ballarat, prevailing throughout the scattered cottages of the country to a most alarming extent, and, in fact, being the only prevalent fever of that settlement.

If such be the case, then, we must look upon it as unique in its occurrence, and constituting an exception to the known laws which regulate this disease. At present, we should be only justified on Mill's principle applicable to exceptions. First, to make quite sure of the fact, and then to investigate the reasons and causes which are sure to exist, if we can detect them, why in this case there should be such an exception to the generally prevalent laws with regard to it. In illustration of the necessity of the first precaution, we may mention its having been asserted that puerperal fever had not shown itself in Kilkenny for twenty years, or within the memory of any existing man. That Kilkenny has not at least been free from it, is conclusive, from the answer of Dr. Lawlor, who practised for many years in that city. He has answered my inquiries on this subject to the effect that he and the late Dr. Cane attended a fatal case in private practice, in the year 1847. Under no circumstances should we admit such an exceptional case to influence us in the results to be drawn with regard to the vital question of isolation in our present discussion.

What would the learned Professor or this Society think of my logic and conclusiveness in reasoning, if I told him that there was a district of the Ojibaway country in which the Indian tribes were never free from small-pox, and then argued on this exception that all children attacked with pyrexia in London and Paris, and the other great cities, might be moved at once into the small-pox hospitals with perfect safety, because they were equally liable to have their pyrexia eventuate in small-pox outside as inside the small-pox hospital? Now, I admit, this sounds very absurd, but to my mind not one particle more so than any argument based upon Ballarat.

We may remark, in passing, that although in the case of poisoning by animal and vegetable exhalations, we have generally the advantage of the physical safeguard afforded by the sense of smell to assist us in their detection and removal, in the group of diseases generated and communicated by crowding we are deprived of this safeguard. All we can usually detect is a close atmosphere and certain exhalations, as in the

lying-in hospital wards, that prevail, whether disease be present or not. This want of notice is unfortunate in this most deadly class of disease; for although we have known of cases in which physicians have spoken of experiencing a certain whiff from the breath of a patient in typhus fever, which they felt at the moment was infecting them, yet this is so rare as not to prove generally valuable as a precautionary symptom. On the contrary, both in the typhoid and ague groups of fever the odour is often a great protection. This is especially observable in tropical climates, where these diseases, and particularly the latter, so much prevail. I was so struck with a communication I had from my son of his experiences on this subject that I am tempted to give it to you. He says:—"In India, we are pretty well broken to bad smells. A dead elephant, no uncommon nuisance to be encountered in a campaign or forced march, is very bad. I have seen a column go round half a mile to avoid one. But, for a good sustained smell, I know of nothing that beats that of decaying vegetation in the Indian jungle. The first time I experienced this was on the march to Bhootan. We were in the Assam country, just on the edge of the Dewars; the weather was very hot; and at first I thought that the offensive odours resulted from the effects of the heat on the large body of men, so I separated myself from the column and went off alone, when, instead of abating, the smell grew rather worse, and I began to think I must be carrying it with me; but on examining, I found that the stench—for it was nothing else—arose solely from the masses of decaying vegetable matter that filled the jungle. Within a few days the men began to suffer from fever, and within one month from the date at which I first perceived the smell, out of our officers, 26 in number, only two others and myself had escaped fever; and among the men the rate of sickness was 60 per cent."

(To be continued.)

DYSPŒA RELIEVED BY THE INHALATION OF OXYGEN.

Four cases of dyspœa in which oxygen inhalation was employed by Dr. A. H. Smith, and gave great relief, are reported in the *New York Medical Journal*. In the first case, one of pulmonary emphysema, with a marked degree of cyanosis, swollen and tortuous veins of the neck, respirations 36 and pulse 122, four gallons of oxygen gas were inhaled with an equal amount of atmospheric air. The pulse fell to 100, the respirations to 20, and the dyspœa was entirely relieved for the time being. A similar result followed the use of the oxygen in the other cases, which were spasmodic asthma, meningitis supervening upon acute rheumatism, and advanced tuberculosis. In an editorial note in the same journal, it is stated that at the New York Hospital oxygen has recently been administered to tubercular patients, and the results thus far have been somewhat extraordinary. The immediate effect of the inhalation of the gas is a marked improvement in the appetite and increase in weight of the body. The gain in weight in some of the patients has been almost marvellous.

IS VALERIAN AN ANTIDOTE FOR STRYCHNIA?

Dr. J. Dabney Palmer (*Amer. Jour. of Pharmacy*) says, that having occasion to poison four cats, he gave to two of them strychnia on pieces of beef; both died. To the other two he gave the poison on tufts of valerian, and without the least effect. The quantity given to each cat was about two grains. The editor of the *Journal of Pharmacy* suggests that the strychnia may have fallen off the valerian tufts if they were dry, and that the experiment is worth repeating to prove or disprove the correctness of Dr. Palmer's inference.

CARBOLIC ACID SOAP.

Mr. Crace Calvert has recently manufactured an admirable medicinal soap, containing twenty per cent. of carbolic acid and an equal quantity of glycerine. The soap is transparent and elegant in appearance, as well as being most useful for the purpose of cleansing and purifying the skin. *Experto crede*, we have used it for several months with increasing satisfaction, and have prescribed it largely among our patients. It is most useful in xeroderma and ichthyodes, in hyperidrosis and osmidrosis, and gives a freshness to the skin unequalled by any other soap. It is mildly stimulant, as well as depurative and disinfectant; and, used to the teeth and mouth, it is very refreshing. In exanthematous fevers, and fevers of every kind, it will be found very valuable.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, OCTOBER 13, 1869.

THE ARMY REPORT.*—No. 2.

DURING the fifty-two weeks ending 27th December, 1867, the average strength of the troops serving in the United Kingdom was 73,420; the admissions into hospital were 63,904; the deaths from all causes were 690, of which 53 occurred when the men were absent from their corps; and the average number constantly non-effective from sickness was 3,118. These numbers give the proportions of 870 admissions, 9'40 deaths, and 42'47 constantly sick per 1,000 of strength, being a slight increase on the admissions. Continued fever has not been so prevalent; but influenza and sore throat were greatly in excess of the average at the stations of the depôt battalions. Euthetic diseases, too, were more prevalent than in 1866 at all the groups of stations, but particularly in the large manufacturing towns. Indeed, a table given shows the admissions by venereal diseases to have been greater than in 1866 at all the large stations except Warley, Canterbury, Winchester, Devonport and Plymouth, and Shorncliffe, where there was a slight reduction, and Chatham and Sheerness, where the ratio of admissions in 1867 was 49 per 1,000 of the strength lower than in the preceding year. The increase was most marked at Manchester, Preston, Dover, the Isle of Wight, Edinburgh, and Limerick. The Contagious Diseases Act of 1866 was in operation during the whole year at Devonport and Plymouth, Portsmouth and Gosport, Chatham and Sheerness, and Woolwich, and for eight months and a half at Aldershot; but the results do not seem as yet to have realised the expectations which were entertained of its effects in reducing the amount of these diseases among the troops, except at Chatham and Sheerness. On comparing the table for 1867 with that for 1866, there will be found an increase in the proportion of admissions into hospital, constantly sick, and loss of service by both groups, but rather greater in the gonorrhœal than the syphilitic, and a decrease in the duration of the cases under

* Army Medical Report for the Year 1867. London, 1869. Pp. 563. London: Harrison and Sons.

treatment amounting to 1·69 days in the syphilitic, and ·79 days in the gonorrhœal group. Deaths from tubercular diseases have been more common than in 1866; and diseases of the respiratory system were greatly in excess of the average. The Lock Hospital at Aldershot has been in operation since June, 1867; no diminution of the admissions from primary venereal sores was yet apparent. During the year 1867, 4,034 patients were admitted into the Royal Victoria Hospital at Netley Abbey, of whom 3,873 were from abroad. It appears that a large proportion of the cases sent from India are much benefited by the long sea voyage round the Cape. At Devonport and Plymouth, venereal disease still remains one of the chief sources of admissions. The increase was caused in the cases by the arrival, on the 26th July, of the *Depôt 1st Battalion 12th Regiment* from Gosport. The Contagious Diseases Prevention Act continues to be productive of good results. In the Report concerning Scotland, it is remarked that, during the past six months, Edinburgh and Piershill barrack occupation has been fixed at the prescribed 600 feet per bed; but the overcrowding of Leith Fort still continues. The invaliding in 1867 was lower in all arms than during the preceding year, and considerably under the average of the eight years. Tubercular diseases have been the most common of all causes, and notably in the Foot Guards. The mortality of the troops over the age of thirty is considerably higher than that of civilians; for example, the Foot Guards had a mortality of 27 in 1,000 men between thirty-five and forty, whilst the mortality in England and Wales of men of the same age was only 11 in 1,000.

On the head of Recruiting of the Army, the returns show that 11,499 recruits were primarily inspected at the head-quarters of the recruiting districts; 6,038 at regiments and depôts; and 9,109 by civil medical practitioners—in all, 26,646. Of these, 10,069 were rejected. Taking the combined results, there has been a reduction of 6 in 1,000 in the rejections for small and deformed chest; and half that amount for varicocele. Of those enlisted a large proportion could not read or write, 222 per 1,000. Among the causes of rejection of recruits are mentioned syphilis, scrofula, phthisis, disease of the heart, varix, loss, or decay of many teeth, hernia, varicocele, diseases of joints, unsound health, hæmorrhoids. Finally, we find that the influence of trades tells in the admission of men into the army, since, of 1,000 labourers, husbandmen, and servants, 368 were rejected; whilst of mechanics employed in occupations favourable to physical development, as carpenters, smiths, masons, &c., 432 were rejected; and of shopmen and clerks, 407 in 1,000 were rejected.

SCOTLAND.

REPRESENTATION OF THE UNIVERSITIES IN PARLIAMENT.

MR. MONCRIEFF'S elevation renders the seat for Glasgow and Aberdeen Universities vacant. It will be remembered that last year Mr. Gordon, LL.D., Q.C., contested the seat on behalf of the Conservatives, and his supporters are already in the field, and entertain hopes of victory. The Liberals, on the other hand, though active, seem less united. Meetings of Liberal electors were held last week both at Glasgow and Aberdeen, and committees appointed to confer together. At Glasgow, Mr. Andrew Bannatyne presided, and Sir William Thompson brought forward the

name of Mr. Smith, of Jordanhill, and recommended him in very strong terms. At Aberdeen, Mr. Stronach presided, and Dr. G. G. Brown advanced Mr. Smith's claims. At a meeting of the English Branch of the Scottish Universities' Union, in London, the name of Mr. John Stuart Mill, as we reported in our last, was brought forward, and a resolution in favour of that gentleman came to. A committee was appointed to confer with those in Aberdeen and Glasgow. We believe it is not probable that Mr. Mill will allow himself to be nominated, in which case it seems likely that Mr. Smith will be accepted by all of his party. We very much regret that no medical candidate has come forward, and even yet advise M.D.'s to abstain from pledging themselves.

As to the Edinburgh and St. Andrew's Universities, we believe there is not a prospect of the vacancy rumoured occurring, on the mere report of which the meeting, as reported last week, agreed to support a medical candidate.

It is likely that the Conservatives would, if such vacancy had occurred, have brought forward Sir William Stirling-Maxwell, so that the supporters of Dr. P. James would have needed the active aid of the medical graduates of all parties.

ADDRESS TO DR. DICKIE, OF ALLOA.

A VERY pleasing mark of the esteem which follows the faithful discharge of medical work, has been conferred on Dr. Dickie, who after practising for ten years in Alloa, is leaving for another sphere. A handsome piece of plate, a purse of new sovereigns, and a feeling address, were presented to the doctor by his patients and friends. Of these, no doubt the address, though the less costly, will be most esteemed. It is in the following words:—

TO JOHN DICKIE, ESQ., M.D., L.R.C.S.E.

DEAR SIR,—It is with feelings of deep regret we have learned your purpose of removing from Alloa to another part of the United Kingdom, there to follow your Profession.

While sincerely regretting your resolution, it affords us no small pleasure to embrace this opportunity of testifying to your qualifications and worth as a physician and surgeon.

Since you came amongst us—now nearly ten years ago—you have won the confidence and esteem of a large number of the inhabitants of this town and neighbourhood, by your professional skill, and the prompt response given at all times, by day or night, to calls for your services; by the kind attention and sympathy shown while with patients, and your agreeable and unassuming manner. For these and other considerations your departure will, we fear, be no small loss to this community.

Animated by these sentiments and feelings, we request that you will be pleased to accept of the accompanying testimonial, viz.—a silver jug and a purse of sovereigns—as a mark of esteem, from a large number of your friends and well-wishers in this town and surrounding district.

We trust that a long and successful career awaits you in your new field of labour, and that, wherever in the course of Providence your lot may be cast, everything that is good may attend you.

Notes on Current Topics.

The Opening at Netley.

THE session at the Army Medical School at Netley commenced on Friday last. As no examinations have been held during the past year in connection with Her Majesty's British service, arrangements have been made for the attendance of a number of the commissioned medical officers (ten surgeons and fifteen assistant surgeons) at the special course of instruction afforded at Netley. Thirty-nine candidates for Her Majesty's Indian Service joined the school on the above day. Professor Aitken, in his introductory lecture at the commencement of the session, briefly reviewed the various campaigns that have taken place during the past fifteen years in

different countries, and pointed out how medical science had thus periodically advanced on sanitary improvements being effected. Commencing with the Crimean war he remarked on the rapid diminution of mortality that occurred when rigid sanitary measures were adopted, reducing in one year the death-rate from 600 to 44, and 33 per 1,000 per annum, and ultimately to 8 per 1,000 at the termination of the war, when the average deaths amongst the infantry at home amounted to 17 per 1,000. The statistical returns since 1859 proved that through the energy of Lord Herbert and the Royal Sanitary Commission the mortality in all branches of the service at home had been reduced one half; and the Circular just issued from the War Office directing that in all future hospital arrangements the percentage of sick accommodation should be six in place of ten as formerly, showed a saving to the country from this attention to hygienic measures of 4 per cent. per annum. Referring to foreign stations, he stated that the health of Gibraltar was even higher than in England; that Newfoundland (if intemperance could be excluded) would be unprecedented in sanitary condition; while the death rate in Canada and the West Indies had been reduced one half within the past fifteen years. In the Canton Chinese war, the exertions of the sanitary inspector, Surgeon-Major Rutherford, the sick were positively reduced to as low a standard as 2 per cent. Dr. Aitken spoke strongly of the necessity that now existed for a reorganisation of the transport service. In reviewing the medical incidents in the late American war he laid stress on the fact that the hospitals, which were all under exclusive medical control, were the most successful ever known.

The Heat in India

THE meteorological reports for last year show that the mean *minimum* temperature at Calcutta (given as average temperature at sunrise) was 70° in the shade. Ninety-one and a half inches of rain fell.

Medical Annuities in India.

THE medical annuity question has been settled by the India Office. They have fixed the annuities at—for Class II. £250, Class III. £210, Class IV. £168. Three annuities of these amounts, one in each class, will be granted annually in future; annuities of £300 will be continued only to the present incumbents in Class I. In addition, the surplus is to be disposed of by the grant of three extra annuities of £252 in the present year. These are regarded as unexpected gifts.

Compulsory Vaccination.

THE following correspondence has been made public :—
To F. S. Chapman, Esq.,

Chief Secretary to Government, Bombay.

SIR,—With reference to the resolution recorded by Government on the 29th May last, authorizing Dr. Pinkerton, Superintendent General of Vaccination, to put himself in communication with the managing committee of the Bombay Association, I have been instructed by the Committee to state, for the information of his Excellency the Right Hon. the Governor in Council, that on reconsideration the Committee are of opinion that it is advisable to make vaccination compulsory in the town

and island of Bombay, but that in framing a Bill for carrying out this object due care should be taken to protect the people against annoyance or extortion, and against the infliction of hardship or oppression.—I have, &c.,

NOWROZJEE FURDOONJEE, Secretary.

Bombay, Association Office, 11th Aug. 1869.

Large Families.

A SCOTCH correspondent sends us the following extract, as a contribution to the discussion in our columns on this subject. He says it is taken from a letter of the London correspondent of the *Elgin Courier* :—

“The pauperism of London alone has been increasing with fearful rapidity; we are at our wit's end for expedients to stem the tide of poverty, and a host of philanthropists are pestering the Government with schemes which, if adopted, would pauperize the whole community. I recently attended a meeting of a learned society which had been specially convened, to hear a paper on pauperism and the poor laws, from the pen of a well-known medical man, who had had years of experience as medical officer and coroner of a large metropolitan district. His scheme astonished everybody, and it is only one of many such. He suggested providing supper, bed, and breakfast for every idle tramp, in exchange for work, which is always unprofitable when wrung from people affected with laziness, the establishment of vast asylums for friendless children, and the erection over the whole country of large hospitals for the sick. Nobody was to starve—all the idle to be fed at the expense of the industrious. Such was the London Coroner's scheme, as evil in its benevolence as any social project could well be. The most unhappy circumstance connected with pauperism—and every political economist is familiar with the fact—is this, that the more you give in the way of charity, the more recipients you create for your bounty. Poor Laws and Boards of Guardians create more paupers than they relieve, and the problem how to assist the deserving poor without degrading and pauperizing them, is one of the most difficult social riddles of the day. Those who have the smallest knowledge of the subject must pity Mr. Goschen, who will be obliged to bring some scheme forward next year. We must hear no more such scandals as that of St. Pancras, and, on the other hand, we must avoid such Utopian projects as that of my friend the M.D. and Coroner.

“There is a school of Malthusians in London who have taken this question, with others of equal importance, under their especial care. They tell us that poor laws and emigration will never diminish pauperism—that the evil lies deeper—that over-population is the cause of the misery under which the masses of our countrymen groan. They talk learnedly of the tendency of population to increase faster than the means of subsistence, and warn us that without provident habits and late marriages, or early marriages and no children, we shall always be in a chronic state of poverty. These gentlemen hint darkly at the artificial checks to population which are common in France, but they have not yet dared to speak plainly. The *Lancet* has attacked their theories again and again with crushing effect, but they, too, are supported by medical opinion, for the doctors muster strongly in their ranks. They are prepared, they say, for misrepresentation and persecution, for they are in the

vanguard of political economy, and when their remedies shall be accepted, universal poverty [and they might almost add population] will be amongst the things of the past. Such are the extremes of opinion on a great social question, and, avoiding both as equally pernicious, the statesman must strike out a path for himself. If Mr. Goschen succeeds, he will stand in the front rank of politicians and public benefactors."

Poisoned by Hair Dye.

ON the 15th of June Dr. Witherwax, of Iowa, died with peculiar and obscure symptoms. The Scott County Medical Society appointed a committee to investigate the causes which led to his death, it having been the opinion of several medical gentlemen that he died from the effects of lead poison.

The committee have prepared their report, in which they unanimously concur in the opinion that the cause of Dr. Witherwax's death was rightly surmised, and that the poison was introduced into the system through the use of hair-dressing or dye. For four years previous to his demise Dr. Witherwax had used the dressing almost daily on his hair and whiskers, and frequently during the whole period suffered from pains which were similar to those produced by lead colic.

Drs. Hazen and Cantwell each made four separate analyses of the liver of Dr. W., and one of the kidneys, and found lead in the tissues of those organs each time. Their report accompanies that of the committee.

Abuses of Vivisection.

WHEN it is found impossible to determine, by observation of cases, a specific fact which it is for the good of the public shall be known, it is quite right to make experiments on the lower animals, every humane precaution being adopted; but it is an abuse and disgrace to science to inflict tortures for the investigation of matters which could quite as perfectly be observed in the person of patients.

A German pamphlet by Dr. G. Wertheim was reviewed not long since in the *Edinburgh Medical Journal*, which contains the results obtained by burning and scalding about thirty dogs. The burns were produced by sponging the chest and bellies of the dogs with oil of turpentine, five or ten times in quick succession, setting fire to it each time; the scalds, by pouring over similar parts eight ounces of boiling water nine times in quick succession.

The results obtained were—all the dogs died, either in a few hours, or, at the latest, five days; in three cases the burned portion of skin was excised two, five, and fourteen hours after the burning. All the three dogs died twenty-four hours after the burning.

A narcotic was administered during the act of burning; but what were the subsequent sufferings of the unfortunate animals, and where are the scientific results of the *auto da fe*?

Threatened Aggregation of Vaccino-Maniacs.

It is proposed to hold a three days' Conference on Vaccination, in Manchester, during the month of December, to be followed by a public meeting in the evening. The idea is to invite our legislators, medical men, ministers, guardians of the poor, sanitary reformers of both sexes, and

sufferers by vaccination, so that the entire question may be thoroughly discussed. The Conference would be held under the auspices of the Manchester League; and the co-operation of the parent and branch Leagues would be invited.

The following is a sketch of the proposed programme:—

First Day—History of Inoculation and Vaccination; Small-pox, its Cause and Cure; Resolutions. Second Day—History of British Legislation upon Inoculation, Vaccination, and Small-pox; Statistics as to Disease and Death; Resolutions. Third Day—Impolicy of Compulsory Vaccination; Cases of Injury by Vaccination; Resolutions. Public Meeting—Speeches and Resolutions.

Pauperism in Scotland.

DR. MITCHELL, reporting to the Commissioners in Lunacy for Scotland, states that on the occasion of his visit to Shetland he saw much stronger and deeper signs of poverty than he had ever seen before. In the parish of Unst, the year's poor rate is no less than 7s. 1d. per pound of the gross rental. When the taxes, charges, and burdens on land are added to this, he was assured that less than one-third of the rental will be left to the proprietor. All over Shetland the poor rate has been rapidly and steadily increasing during the last twenty years—the increase in some parishes being 700 or 800 per cent. In the parish of Lerwick it is said to have risen since 1845 from £40 to £900.

The Hospital Dinners.

THE veteran Sir Charles Locock presided at the St. George's, and about 100 gentlemen, many of them from a long distance, assembled to do honour to him and their School.

At the Middlesex, Dr. Stewart took the chair, and nearly as many were present.

Sir H. Thompson, who had delivered the Introductory in the afternoon (Monday, the 4th), presided at the University College Dinner in the evening.

Last week we noticed the London Hospital Dinner, and the St. Bartholomew's is mentioned in another paragraph to-day.

St. Bartholomew's Hospital.

AT the annual dinner, Mr. Holmes Coote presided. Mr. Paget gave the health of the Governors. In the course of his speech he said:—

"He wished it to be clearly understood that complete concord existed between the governors and the medical staff in the discussions about the administration of out-patient relief; that the matter was still under discussion; that it was a grave question as to whether the number of out-patients should be diminished, or the medical staff increased; that delay was not synonymous with discord; that both governors and staff were at unity in design and purpose in solving the difficulty for the advantage both of hospital and school; and that Mr. Clifton, with other medical men now on the board of the governors, would, he was convinced, give right words at the right time and place."

Considering what occurred that day "at another place," this is the most astonishing utterance to which Mr. Paget has ever given expression. We last week gave the resolutions passed by the students. Had we had space to report

the speeches, they would have as completely contradicted Mr. Paget's view as it is possible. The public has fully endorsed the students' complaints, and delivered a verdict in favour of enlarging the staff. From the dullest of the newspapers to the frolic of *Punch*, all writers endorse what we have written.

The late Surgeon-Major S. H. Batson.

THE *Jubbulpore Chronicle* announces the death of this retired medical officer. He died at Dinapore on the 27th August, from a severe relapse of hæmorrhagic dysentery, the first attack of which occurred a month ago. It is believed, and no doubt with truth, that the exposure to the late fearful heat, which his trying duties as medical officer to the railway community at Dinapore subjected him to, had a great deal to do with the disease which carried him to his grave; and if this is correct, his case adds one more to the long list of deaths caused by the extreme heat of this terrible '69. Dr. Batson was an officer who will be remembered by old Indians, but mostly known to others in connection with his marvellous escape from Delhi in May '57. He volunteered to convey a letter from Brigadier Graves, commanding at Delhi, to the General at Meerut asking for assistance, and having disguised himself as a *jogee*, one of the most difficult characters to personate, succeeded after much wandering and several hairbreadth escapes, in reaching the latter place. The mutineers several times were about to murder him because he had blue eyes, a fact which made them very suspicious about his being a real *jogee*, yet his knowledge of the mutterings and incantations, and his colloquial mastery of the language, always raised a doubt in their minds, the benefit of which he invariably reaped.

American Medical Missionary in China.

THE American Presbyterian Mission has a medical missionary department in Canton and vicinity. It has done a great deal of work the past year, treating 50,636 out-patients and 1,038 in-patients, and has performed 1,038 surgical operations, some of them of great importance. A medical class numbers 12 scholars.

Asylums for Inebriates.

IN the British North American Provinces, at the present moment, there is considerable agitation on the subject of Asylums for Inebriates. The Legislatures of Ontario and Nova Scotia have been memorialized in favour of the establishment of such institutions. Petitions will be presented to both bodies at their next sittings, and it is anticipated that the Dominion Parliament will also be requested to do something in the matter, and a strong pressure has been brought to bear on the Legislature at its next Session, with the view of obtaining a grant from the Treasury towards the erection of a suitable building or buildings for a home for Inebriates in Nova Scotia. In the United States it has been estimated that fully *eighty per cent.* of those treated in Inebriate Asylums have been reclaimed and continued faithful to total abstinence principles.

Health of Dublin.

IN the Dublin Registration District, the births registered during the week ending October 2nd, amounted to

144. The average number in the corresponding week of the years 1864 to 1868 inclusive, was 186. The deaths registered during the week were 147. The average number in the corresponding week of the previous five years was 164. Scarlet fever caused 13 deaths. A like number of deaths from this disease was registered in the week preceding. Six deaths resulted from fever, viz., 2 from typhus, 1 from typhoid or enteric, and 3 from simple continued fever. Measles caused 9 deaths. Twenty deaths were ascribed to diarrhœa, showing an increase of 9 as compared with the week preceding. Fifteen of the persons who died from diarrhœa were children under 5 years of age. Twelve children were carried off by convulsions. Nine deaths were referred to bronchitis, and 5 to pneumonia. Three deaths were attributed to heart disease, and 1 to aneurism. Apoplexy caused 3 deaths, and paralysis 2. Five deaths were the result of liver disease, and 3 of kidney disease, one of the latter being from nephria or Bright's disease. Phthisis caused 11 deaths, mesenteric disease 4, and water on the brain 3. Delirium tremens proved fatal in 2 instances.

Dangerous Ground.

It is proposed to start in New York a popular medical paper, to be issued weekly, and to contain short editorials on some popular medical subject, and answers to all sorts of questions about health and remedies for disease.

If we understand the announcement to mean that the projected journal is to act as general medical adviser to all comers, we have only to say that it cannot possibly be useful, but must be a source of great danger to the public. The medical men connected with the venture must know this, and therefore are the more blameable.

A Pleasurable Reminiscence.

MR. SANDBERTSON describes, as far as the power of language enables him, his sensations when undergoing the operation of scalping.

The observation is original, and as it is improbable that any investigator will venture to interfere with the author's monopoly in the inquiry, we reprint the description:—

"The Indian stepped one foot on my chest, and with his hand gathered up the hair near the crown of my head. He wasn't very tender about it, but jerked my head this way and that, like Satan. My eyes were partially open, and I could see the bead-work and trimming on his leggings. Suddenly I felt the awfulest biting, cutting flash go round my head, and then it seemed to me just as if my whole head had been jerked clean off. I never felt such pain in all my life; it was like pulling your brains right out. I didn't know any more for two or three days, and when I came to I had the sorest head of any human that ever lived. If the boys killed the viper, they didn't get back my scalp; perhaps it got lost in the snow. I was shipped down to Laramie after a bit, and all the nursing I got hain't made the hair grow out on this spot yet."

Californian Bathing Geysers.

THE natural bathing facilities at the Californian Geysers make the locality one of the most popular resorts on the Pacific coast. The ordinary bathing establishment is a feature in its way. It is primitive in its construction, being built of rough boards, and portions of it covered with

gunny sacks, yet contains natural steam, hot water and cold water baths. One room is directly over a volume of steam, which rises from the earth and fills the room, so that upon first entering it the heat and steam are almost unbearable; but in a few seconds become quite comfortable, and in a short time are luxurious. The bather, having steamed himself sufficiently, two steps brings him beneath a stream of hot water, which pours through the roof in a continual volume, and is of just bearable heat: Having steamed and boiled, the bather steps a few feet and plunges into the running brook, which is waist deep, with pure water, cool and fresh from the mountains above. The effect of this course of bathing is to leave the bather refreshed and invigorated in a wonderful degree. Separate establishments are erected for ladies, and with the same facilities.

Election of Assistant-Surgeons at the London Hospital.

WE last week alluded to some remonstrances we had received respecting this election. We have since been favoured with a letter from Mr. Rivington on the subject. As he is the Dean of the College, we have thought it best to give insertion to his letter instead of others. It certainly seems to us to call for explanation. The mode of election, he tells us of, was certainly not that which received our approbation. We certainly think there is need for change in the election of the staff of hospitals, but should be the last to favour a sham system.

Life Assurance.

THE present is a time when the public mind is deeply agitated on the subject of life assurance. It would be a great pity if the recent disclosures were to undermine the faith of the prudent in this mode of providing for families. Medical men's lives are mostly just those that ought most to be assured. We, therefore, direct special attention to the letters of Mr. F. A. C. Hare on this subject, the first of which appears in this day's issue. Mr. Hare has paid much attention to the subject—has studied it practically as well as theoretically both in Europe and America, and we trust our readers will think we do well in procuring for them a series of communications from his pen.

Medical Examination of Recruits.

THE Adjutant-General, Lord William Paulet, has published, in general orders, the following in reference to recruiting:—"It having been decided that the medical examination of a recruit by the staff-surgeon at the headquarters of a recruiting district shall be regarded as final, the present practice of assembling medical boards to review such decisions is to be discontinued. On the arrival of a district recruit at the head-quarters of a regiment, or depôt battalion, the surgeon in charge thereof, should he not concur in the opinion of the district staff-surgeon, will fill in W. O. form 584, countersigned by the principal medical officer, should there be one at the station; and the officer commanding the regiment or depôt battalion will then forward this report to the adjutant-general for decision, stating his opinion whether the recruit be eligible and likely to re-enlist should he be discharged. This form must contain the fullest information as regards all the medical disqualifications. District recruits, passed by

civilian medical practitioners (including Militia medical officers), if found unfit by the district staff-surgeon, will, with the concurrence of the inspecting field officer, be discharged without further reference, but the report on W. O. Form 584 will always be sent in duplicate to the adjutant-general. The inspecting field officer, should he consider the recruit eligible and likely to re-enlist, can detain him till the decision of his Royal Highness the Field-Marshal Commanding-in-Chief be given. When a district recruit is passed primarily by a military medical officer, and considered unfit by the district staff-surgeon, W. O. Form 584 will be sent in duplicate to the adjutant-general for instructions as at present. The medical examination by civilian medical practitioners of district recruits is not considered final. When a district recruit is considered unfit by a regimental surgeon, he will bring him before the principal medical officer if possible, and, should he concur in the unfitness, report the case to the adjutant-general on W. O. Form 584, in duplicate, for further instructions, through the commanding officer. These instructions modify paragraph 1351 of the 'Queen's Regulations and Orders for the Army,' bringing all cases of medical disqualifications under section 'd' of that paragraph."

Vaccinomaniac Logic.

THE propriety of learning before they teach has been so persistently pressed upon the vaccinophobias without result, that we feel diffidence in suggesting that some slight knowledge of logic and argument would enhance the force of the conclusions which they are trying to force upon the public. Their ignorance, or wilful blindness to the facts and figures with which everyone else in the world is familiar, is paralleled by the abortions of reasoning which seem to pass current with the readers of the "Anti-Vaccinator." Here is a specimen:—

"In order to prevent disease, we are told to be inoculated with disease. On the same principle you ought to have your children inoculated with the virus of carbuncle in order to prevent their contracting it; with the pus of abscesses to prevent their suffering from them; have them inoculated as a preventive against typhus, consumption, rheumatism, cancer, and other afflictions, with the virus or active animal poison of these diseases. It is about as rational a proceeding and as sound in theory as vaccination, as inoculating small-pox or cow-pox matter from the diseased cow—for all cows are diseased whose teats are ulcerated—as a preventive against the onslaught of that disease. No earthly remedy, be it ever so harmless; no poison, be it animal, vegetable, or mineral; can prevent disease. The only preventive is a natural mode of living. An artificial mode of living, an encroachment on nature's laws, brings its penalty—disease to the individual—as surely as a defective sanitary state produces epidemic or endemic disease among populations. An observance of nature's laws is the only preservative against disease—there is no other."

The notice of such depressing nonsense requires an abject apology to our readers. What is the analogy of carbuncle, abscess, typhus, phthisis, rheumatism, or cancer, to small-pox? Does anyone (except persons who might, as far as education is concerned, be vaccinophobias) inoculate small-pox? We think not. Jenner inoculated children with a disease (if it be called so) almost altogether innocuous, to protect them from a loathsome and fatal disease which most probably they would otherwise suffer from. What, then, is the parallel between Jenner and one who would inoculate with loathsome and fatal diseases in order to protect the recipient against the indefinitely

improbable contingency of the same, or a less hurtful disease?

To substitute a nominal condition of disease for a pressing and urgent danger is good sense; but to communicate a fatal and disgusting malady, which he would most probably never take, to save the patient from receiving the infection in the ordinary way would be madness. Can the vaccinophobiacs point out "the natural mode of living" which will protect us against small-pox? If not, we advise the public to secure themselves, as experience proves that they may, until we can have something less vague and impossible than the anti-vaccinators have yet propounded.

Alpine Desagremens.

THE compound of vanity and foolhardiness which is developed now-a-days in the form of Alpine climbing has been applied by M. Lortet, of Lyons, to scientific purposes, and he has expended much time, money, and trouble in the investigation of phenomena which, at least, can never harm sensible people, but which is interesting from a medico-scientific point of view.

M. Lortet ascended on the 17th and 20th of August, to the summit of Mont Blanc, furnished with all the instruments necessary to investigate physical effects, amongst which were the anapnograph of M. M. Bergeon and Kastus, the sphygmograph of Marcy, thermometers, &c.

M. Lortet has experienced and verified all the phenomena known under the name of *mal des montagnes*, consisting principally in acceleration of respiration, frequency and feebleness of the pulse, lowering of temperature during the journey, and its return to the normal condition during rest, muscular fatigue, loss of appetite, occipital headache, nausea, somnolence, &c.

He attributes, like M. Gevarret, the coldness of the body during exertion to the insufficiency of the internal combustion which, to maintain the temperature, has to contend at once against the extreme cold and the loss of heat transformed into mechanical work. The other symptoms are the consequence of the cooling, and probably of the vitiation of the blood by carbonic acid, whose elimination is incomplete.

The Milk of Diseased Cows.

THE foot-and-mouth disease is acquiring larger interest as it spreads. A very important question has been brought forward since it extended to the Metropolis, viz., whether the milk of the animals would be likely to injure those who consume it. We are glad to see that Dr. Whitmore, the medical officer of health for Marylebone, has persuaded the dairymen of his parish to throw away such milk. It was a general opinion with the public that the first symptom of the disease was a stoppage of their secretion; but this is not the case, and it is impossible to deny that children might suffer from being fed on the milk of diseased cows. Experiments have been made, it is said, but at present the only safety is in caution; for the effect of disease on the milk is undetermined.

Proposed Hospital for Incurables, near Oxford.

WE have seen the Prospectus of a National Hospital, to be erected at Cowley, near Oxford. The best feature of it

is, that admission is to be free as far as accommodation may admit, and that the pernicious system of canvassing will find no place. Cases will be selected from those recommended by medical men, and professional advice will be followed in the choice.

From a medical point of view the institution is certainly to be recommended; and already Sir T. Watson, Sir W. Fergusson, Drs. Bennett, Beale, Andrew Clark, G. Johnson, Pollock, and Messrs. Brooke, Le Gros Clark, Curling, Prescott Hewitt, Solly, and others in London, besides most of the Profession in Oxford, have expressed their approval. A site has been presented, and a certain sum already obtained. About £50,000 is wanted. We heartily wish the scheme success. Miss Sandford, of Cowley, St. John, Oxford, will gladly furnish any further information.

At last Hebra, and Sigmund, of Vienna, who for twenty years were professors extraordinary without any remuneration, have been appointed professors in ordinary—a just but tardy recompense for their zeal.

THE inauguration of Dupuytren's statue will take place in the town of Pierre-Buffière, on the 17th of October, in the afternoon, and will be followed by a banquet, which will take place at four o'clock.

It is encouraging to know that in many parts the questions relating to medical relief are being taken up by journalists and others. The *Herts Advertiser* this week admits a letter from Dr. Spackman, of Harpenden, in which some very useful home-truths are brought under the notice of ratepayers.

THE Birmingham Guardians have been exhibiting themselves in a new capacity. Dr. Heslop has written a pamphlet, and these local worthies think themselves described in it. Their portraits do not please them, so they have been calling Dr. Heslop bad names, and displaying in public more ill-temper than an over-petted beauty who had been painted with too minute attention to her more defective features.

DR. EDWIN HEARNE, of Southampton, has been made a magistrate. There is ample opportunity for a further addition to the bench from the ranks of the Profession. Medical men, as educated gentlemen, whose experience is of peculiar value at times, have been too much overlooked by the Government. We think the Conservatives made more magistrates than the Liberals are now doing. The Government should take the hint.

AT a meeting of the Medical Committee of the Metropolitan Free Hospital last week, the subject of Remuneration of the Medical Staff was discussed. It was unanimously resolved that, in Public Medical Institutions which do not possess medical schools, or other indirect source for remunerating the medical officers, there should be a payment made to them out of the general funds.

THE medical officers of the United States Navy are invited to forward to the Bureau of Medicine and Surgery, with a view to publication, any reports or essays on pro-

fessional and allied scientific subjects that they think will convey valuable and useful information.

These papers will be submitted to a competent Board, and such of them as the Board may recommend published by the Bureau.

THE Sanitary Commissioner with the Government of India has addressed a circular letter on the subject of cholera to the officers in medical charge of European troops at all stations, whether lately visited by the disease or not. This letter contains a formidable array of questions,—150 in number,—which are to be answered as soon as possible after the 1st October. There can be no doubt, however, that if all these questions are answered from distinct knowledge, and with nothing of hearsay or conjecture, the result must be within a very few years such a mass of information regarding the habits of the disease as will permit a confident induction upon the method of escaping it.

The Fothergillian Prize.

THOSE of our readers who intend competing for the Gold Medal, value twenty guineas, awarded annually by the Medical Society of London, are referred to our advertising columns for the terms upon which the competition is conducted. Essays for 1871 must be "on some subject in obstetrics" (including the diseases peculiar to women), which must be delivered by the end of October next year.

SOCIAL SCIENCE CONGRESS.

DR. SYMONDS, in his address as president of the Health Department, dwelt at some length upon the necessity for efficient machinery and a greater number of workers, if hygienic improvements were to be carried out to any adequate extent. Referring to the vaccination question, he said:—"It would seem that a semi-panic has been excited by a report that cases have occurred in which there was reason for suspecting that the virus of disgusting and deteriorating disease had been diffused by vaccination. Even were it admitted that a constitutional fault, inherited from vicious parentage, could be communicated through the vaccine lymph, still all that we have to be anxious about is the selection of proper sources of lymph. We do not leave off eating bread because bread is sometimes adulterated. And as to the infringement of the liberty of the subject by compulsory vaccination, it must be borne in mind that our object in forcing vaccination upon parents is not so much that their offspring should be preserved from small-pox as that their children may not become the contaminators of their neighbours and perhaps of the whole community. I have just read a report of a quite recent discussion in the French Academy of Medicine of this fear of contamination from cow-pox, and I am glad to say that the result was enormously preponderant against the alarmists. And so I trust that compulsory vaccination will not give an inch to this foolish and petulant opposition." At its close the address of the president noted that much confusion and darkness prevailed in the work which the Department of Health undertook; "but there was no reason to doubt that in all honest scientific inquiries and strenuous endeavours to act, the great forces of nature would be brought to act on the side of human wants, and that the seeming hostilities would be limited and subdued by human will. It requires strong faith, however, in the ultimate triumph of good if we venture to hope that the causes of hereditary diseases will decline and die out, that new modes of living and new political and social developments will eventuate in the growth of stronger and higher human types, which types will become dominant, and either transmit robust and sounder frames and more powerful faculties, or at least become the objects of that passive imitation which has been believed, even in historic times, to have insensibly moulded nations into finer forms, with grander aims and larger capacities. One of the strangest and saddest of the necessities of our present degree of civilisation will long before such a state of things have fallen into desuetude; for we must call it a necessity in the present

state of the world, with its present ways and opinions and practices. I mean that which fills the columns of newspapers with experiments on explosive compounds, that have no other object than the destruction or mutilation of that which this association takes under its special thought and care. That there should have been coeval with this society such institution, for example, as the Ordnance and the Admiralty, will seem in other ages an unintelligible anomaly. Nearly two thousand years ago it was said *Si foret in terris videret Democritus*, but how inextinguishable would be the laughter of that resuscitated sage if, after we had commanded his reverent and admiring attention to an exposition of the religion of the Sermon on the Mount, and after we had assured him that this religion had been publicly professed in these realms for more than a thousand-years, we should then take him on one of our grand days to Shoeburyness!"

Dr. Symonds's address was listened to with great interest, and a cordial vote of thanks was passed, on the motion of Sir Edward Strachey, who presided in the absence of Sir Stafford Northcote.

THE CONTAGIOUS DISEASES ACT.

MR. W. P. SWAIN, M.R.C.S. of Devonport, read a paper on the working of the Contagious Diseases Act in that town. He thought the Act of last Session bore on the face of it hasty legislation. Section 3 provided that if any woman who comes for examination was in such a condition that the surgeon could not properly examine her, and if he suspected her of having a contagious disease, the woman was liable to be detained in a certified hospital for five days, until the surgeon could make his inspection. This Mr. Swain objects to, thinking that by this clause a woman is liable to be deprived of her liberty on police information. The results of the Act, on the whole, were satisfactory. The disease had decreased among men in the garrison, and the vacant beds at the Royal Albert Hospital had increased. Referring to the supervision of the police, Mr. Swain thought that if the Act was extended to civil towns a visiting surgeon would be the best controller. It is sought to vest in the surgeon at Devonport the power to interfere with the treatment of a woman after entering the hospital; but against this the writer of the paper strongly protests, as it would confer on the surgeon the office of prosecutor, judge, and gaoler. As to the effect of the Act on the women, Mr. Swain thinks it has rendered them more orderly and quiet in their demeanour, and the hospital has a humanising effect upon a woman's mind. From April 1st to September 30th, this year, 19 have been sent to reformatories, 12 have gone to their homes, 1 has been married; total, 32 reclaimed.

A discussion, from which ladies were excluded, took place on the question whether the provisions of the Contagious Diseases Act should be applied to the civil population. Several advocates were heard on each side.

The result of the discussion, which was a stormy one, was, that a resolution was passed as a recommendation to the Council, to the effect that the provisions of the Act should not be extended to the Irish population.

Correspondence.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The stoppage of the Albert and European Life Assurance Companies, which, by reason of the many other offices they have from time to time absorbed, may in reality be looked upon as a general winding-up of about sixty such institutions, cannot fail to remind attentive and shrewd observers of the absurd manner in which agents and others connected with assurance business, together with many newspaper writers on the subject, have been in the habit of preaching up the absolute security of such investments. They would, forsooth, have had us consider our policies as safe, if not, indeed, a little safer, than the Bank of England, and Life Assurance Companies as alone "infallible." It has often been said that, with one or two fraudulent exceptions, no life offices have ever failed. This, doubtless, until lately, was perfectly true; but, seeing that the maximum of mortality in an office is not reached until about forty years after its establishment, how few companies have as yet reached the time for their solvency to be actually put to the test!

The fact is, that the nature and character of life assurance, so little understood by the general public, is such that "an

office," as Professor de Morgan remarks, "may be in reality insolvent many years before the symptoms of bankruptcy come on."

It is true that the bases upon which "nett" rates of assurance are generally, perhaps universally, calculated, are to be most implicitly relied on, inasmuch as the average duration of human life at all ages, in Great Britain at least, have, without doubt, been satisfactorily ascertained. And by "nett" rates I would be understood to mean those rates which are derived directly from the mortality table, and to which no addition has been made for the purpose of covering expenses of management, losses by bad investments, or contingencies of any kind other than that of death. The rate of interest, also, which is usually assumed in life computations (namely, three per cent.) is one which experience has shown to be more than easily realized in the past, and which there is little doubt will be equally obtainable for the future, and that by means of the safest investments.

The business of life assurance, however, it is hardly necessary to say, could not be conducted on "nett" rates. A percentage (styled "loading") is added to provide for the expenses, losses, and contingencies before alluded to, while such part of it as in the actual practice is found unnecessary for these purposes, goes both in mutual and mixed offices to form the nucleus of the bonus fund. The "loading" generally allowed for these purposes is twenty-five per cent. Is it not clear, then, that if the expenditure of an office should at any time exceed this percentage, the directors must either eat into that portion of the premiums which is absolutely needed to meet the actual losses from death, or into the paid-up capital of the mixed or into the loan fund of the mutual office? If, moreover, this extravagant rate of expenditure be persisted in until and after there be no capital or loan fund to draw from, then the sacred portion of the premiums must of necessity suffer, and the downfall of the concern become merely a question of time.

From what has been said it is easy to see that, outside of intentional fraud, the security of an office depends mainly, if not entirely, upon the skilful and economical conduct of its affairs. For this the public have perhaps no tangible ground of confidence, but in the ability and the integrity of the manager. Generally speaking, directors have little or no knowledge of the subject. Happy those policy-holders who are assured in offices where the Board is constituted of honest business men! Too often, however, those who sit at it are like so many puppets in the hands of an adroit wire-puller.

Far be it from me to throw out any insinuation against the managers as a body. Many of them are as honourable as they are clever. I am free, nevertheless, to express the opinion that men who out of their hard earnings pay a fair consideration every year throughout life for the praiseworthy object of providing for their widows and fatherless children, and who, in so doing, do at the same time, indirectly perhaps, but no less surely, confer a benefit upon the State, are most eminently deserving of the strictest security that Government inspection could afford them. This protection I most sincerely trust they may soon have. That men acting from such worthy motives should be left to contemplate a suit in Chancery, or their wives and families be dependent upon the good faith of persons of whom they know little or nothing, is, I say, a state of things much to be deplored.

In conclusion, it may not be out of place to give your readers the following advice in the selection of an office, and to suggest that they look as closely as they have the opportunity of looking into the general character as well as the special ability of the manager, and that they examine as thoroughly as they may the accounts. These ought to be published annually, the non-observance of this salutary rule being in itself a ground for discontent, if not of suspicion and alarm, and they should also be full, explicit, and readily understood. Note well the amount of the accumulated fund, which should at least equal the present value of the sums assured, less the present value of the "nett" (not "gross") premiums to be received; for the loading, which is included in the "gross" premiums, cannot fairly be discounted, unless the expenses, &c., for which it is added be also discounted and placed to the opposite side of the account. Should the accumulated fund honestly estimated be five times larger than the total annual income, the safety of the office would, I should say, be without question. It would be a safe and just rule to regard with jealousy and mistrust all mystery and seclusiveness, and to evince a preference, other things being equal, for such companies as invite and would hail Government inspection, in comparison with those who oppose and resent the idea. The point of economy

is, as I have before intimated, one of paramount importance, and must on no account be overlooked. The nature and extent of the advertising are things to be keenly investigated. The remuneration of officers, both in amount and in kind, is an important element for the formation of a judgment, and especially the commission paid for agency. The payments to the manager should be scrutinised with a special view to discover whether he receives any percentage on account, either of premiums received, or of bonuses disbursed, and, if so, at what rate. Especial care should be taken to avoid the snare of delusively low premiums and excessive bonuses. It is better to pay a little more and secure safety. If there be capital in the company you are investigating recollect that for the extra security afforded by it you will have to pay, and that *par consequens* you are entitled to expect, such portion of the capital as the shareholders receive consideration for, to be paid up. There is no necessity to go further than the action now pending between Mr. Lee and the Albert Company, to ascertain the very slight value attaching to unpaid capital. Nevertheless, it is as well to have all the claim you can upon the shareholders. My closing advice, then, is not to accept policies in which clauses are inserted limiting the liability of *so-called* "unlimited companies."

Your obedient servant,

F. A. C. HARE.

Chester: October 1, 1869.

THE APPOINTMENT OF ASSISTANT SURGEONS TO THE LONDON HOSPITAL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Deriving your inspiration evidently from the same source as the *British Medical Journal*, you state in one of your "notes on current topics" that the Committee after "consultation with the Staff," recommended Mr. Macarthy and Mr. Reeves. To consult the Staff is, properly speaking, to consult the Medical Council, which consists of the Staff, and for members of the Staff to take the responsibility of advising the Committee irrespectively of the views of the Council, has usually been regarded as an irregularity. Allow me, therefore, to assure you that the opinion of the Medical Council was never asked. Such a step would, I believe, have been more satisfactory than the mode of procedure actually adopted. Of course, the House Committee can consult whom they like, and are not bound in any way to consult the Staff as a whole. But on general grounds, it may fairly be said, that when a body like our Council exists for the purpose of deliberating on all matters connected with the professional working of the hospital and college, it would be an invidious and injurious procedure for the House Committee of the hospital to select any member or a few members only of the Staff, as their adviser or advisers.

The welfare of the institution, the harmony between colleagues, and the just interests of the pupils, would be endangered. That this has been so at the London Hospital I am not asserting: but I know that the Council was not referred to at any time, and that the consultation of the Staff, spoken of by the *British Medical Journal*, was of a private, confidential, limited, and retiring character.

Your remark that the London Hospital men passed over were considered rather young for such a post seems to be similarly inspired. It may be that they really were. But it seems rather strange that such a plea should be put forward after the lapse of the lengthened period during which youth has been considered no obstacle at all. One of our best surgeons—a man of whom we are legitimately proud—and who has recently retired from the Staff, was elected at an earlier age than that of one at least of the elected candidates. His immediate predecessor and one of our most popular teachers was similarly situated. So was a very able and enterprising young surgeon, who has left us for better things in China. So were two of our assistant surgeons, now on the Staff, whom we are glad to call our colleagues. When they were elected at the end of last year, and at the beginning of this year respectively, we heard little or nothing of the drawback of youth. Nay, with some, youth was regarded as a positive advantage. Yet now in the most puzzling manner a candidate, who is a London Hospital man, and described as "eligible," "suitable," and a "very able" man, by the soothing pen of the annotator, in the *British Medical Journal*, is talked of as "rather too young" at twenty-six, when

others have been considered of a most desirable age at twenty-one, twenty-two, twenty-three, twenty-four, and twenty-five. The apparent inconsistency equals any exhibition of a like kind by members of the softer sex. Your consolatory remark that the rejected candidates can afford to wait is poor comfort, because the idea never struck them when they applied for the appointments.

Allow me to add in conclusion, that though I derived much amusement from the perusal of the ingenious paragraph in the *British Medical Journal*, I do not for one moment intend

to cast any slur on the good faith of those concerned in the election. Advisers and advised alike acted, no doubt, with a single eye to the welfare of the hospital. Only, I should have been glad if the consultation had been arranged on a more generous scale, and I have my own private opinion in regard to the extreme wisdom of one or two of the rejected candidates who accepted the award of the House Committee at a slack period of the year. I am, Sir, your obedient servant,

WALTER RIVINGTON, B.A., F.R.C.S.

Inventions.

THE NEW INFANTS' FEEDING BOTTLE.

THAT the artificial feeding of infants has come to be a necessity to the infirmities and pleasures of "Mothers of the Period," witness the competition of Liebig, Improved Liebig, Farinaceous, Revalenta, and other foods, for the approval and patronage of the autocrat of the nursery. The mother who lacks the maternal aliment can now buy, for a shilling or two, so close a counterfeit as may cheat the baby not only into good temper, but into thriving and getting fat. Even the method of cozening the infant into swallowing his food is progressive. No longer are our sensibilities shocked by the spoon-feeding process to which we have been accustomed, the moulthing of the food by the nurse to ascertain its heat, the skilful smothering of the cries of the semi-asphyxiated victim in a mouthful of pap, and, then, the assiduous scraping up with the spoon of the superfluous food. If feeding bottles have been more plea-

sant to the feeder, and more convenient to the nurse, they have been less safe, being, in the hands of a lazy nurse or inexperienced mother, little better than a gag whenever the baby cries. The old bottle, which is held in the hand with all its leakiness and discomfort, has returned to favour on this account; and now, in the "Mamma" bottle, we have an improvement which promises everything that can be desired. This bottle is patented by Mr. Perrett, of King street, Cheapside, and the sketch below will give our readers a knowledge of it. While it is for use, it has the great merit that it cannot easily be put into the child's mouth and left there. The nipple is done away with, and a soft Indian-rubber shield made in shape and size to imitate the breast. A valve is attached at the upper end which admits the air, but will not allow the liquid to run out, and as the valve is not in contact with the food, it cannot sour it even if left unwashed. Simplicity and cleanliness are ensured, and in every respect the bottle seems to remedy the faults of the old shape, without incurring the evils of the new.

DINGLE UNION.

APOTHECARY for the WORKHOUSE and DINGLE DISPENSARY WANTED.—The BOARD of GUARDIANS will, at their Meeting, to be held on THURSDAY, the 30th inst., proceed to appoint a qualified Apothecary for the Workhouse and Dingle Dispensary. Salary £50 per annum.

Applications for the office, accompanied by Testimonials, &c., will be received by me up to 12 o'clock on the day of election.

By order, P. KENNEDY, Clerk of the Union.

Dingle, 16th September, 1869.

CHURCH STRETTON PRIVATE ASYLUMS

FOR the UPPER and MIDDLE CLASSES of BOTH SEXES, are situated among the Shropshire Hills, Twelve Miles from Shrewsbury, on the rail to Hereford.

Consulting Surgeon—W. J. Clement, Esq. M.P. for Shrewsbury. Physician and Surgeon—J. R. McClintock, Esq., M.D., late Assistant-Physician, Royal Asylum, Perth.

Apply to Wm. Hyslop, Esq., Stretton House, for Gentlemen; Mrs. Bakewell, the Grove, for Ladies. Church Stretton, Shropshire.

Vide page 1016 in the Medical Directories for 1867.

PRIVATE RETREAT

FOR THE UPPER AND MIDDLE CLASSES OF BOTH SEXES, MENTALLY AFFLICTED, TUE BROOK VILLA, NEAR LIVERPOOL.

Further information may be obtained on application to Dr. H. OWEN, Vide page 1075, "Medical Directory," 1869.

FRY'S CARACCAS COCOA,
prepared with the celebrated Caraccas Nut.

FRY'S CARACCAS COCOA
owes its fine aroma and especial excellence to the Cocoa imported from the Caraccas, so long celebrated for the production of the finest Cocoa in the world and to other choice growths selected for their peculiarly delicious flavour.

FRY'S CARACCAS COCOA
will prove to persons in delicate health or under medical treatment a valuable and favourite article of diet.

C O C O A .

HANDFORD and DAVIES continue to Manufacture Cocoa precisely in the manner as in the year 1851, when the ANALYTICAL SANITARY COMMISSIONERS employed by the *Lancet* pronounced so favourably of it.

Pure Granulated Cocoa, in 1lb. packets, 1s. 2d. per lb.
Homœopathic ditto, in 1lb. canisters, 1s. 2d.
This latter is most convenient for gentlemen in chambers, and for use at sea, being prepared on the instant by the addition of boiling water, and, though not entirely cocoa, will be found very superior to similar manufactures.

Cocoa Nuts, 1s. per lb.; Cocoa Nibs, 1s. 2d.; Cocoa Shell, 4d. per lb.
French Chocolates, and that of principal English manufacturers, kept in stock.
61 High Holborn, London, W.C.

DUNN AND HEWETT'S

SOLUBLE COCOAS and CHOCOLATES

CARACCATINA: a Cocoa deprived of its Butter.....	Per Packet. for Invalids.	1s. and 2s.
CONCENTRATED MEAT COCOA.....		9d., 1s. 6d., and 3s.
LICHENISLANDICUS, or ICE-LAND MOSS COCOA.....		1s. 4d. per pound.

To be had of all respectable Grocers and Chemists.

MANUFACTORY:

PENTONVILLE ROAD, LONDON

VAN HOUTEN'S COCOA.

The only guaranteed Pure Soluble Cocoa, and better than any other Cocoa, Cocoa Extract, or Essence, or any Chocolate sold in this Country.

PRODUCES with boiling water *instantaneously* a most wholesome and delicious beverage. *No milk required.*

Dr. HASSALL tested and contrasted it with the best descriptions of Cocoa and Chocolate to be found in the English market, and says:—"While the great majority of them consist of MIXTURES of Cocoa, Starch, &c., VAN HOUTEN'S is not only composed solely of the Cocoa Bean, but this of the finest quality."

The *British Medical Journal*, 27th March, 1869, observes:—"Van Houten's Extract is admirable. In flavour it is perfect, and it is so pure, well prepared, and rich in alkaloid, that it may with great advantage be largely used in public institutions as well as in private families. It is difficult to say how much harm is done by the excessive tea-drinking which is prevalent among women of all classes, and especially among the poor. For health, strength, and good digestion, Cocoa, if properly prepared, is infinitely to be preferred."

Sold in round tins of 1lb., 3lb., and 1lb., at 3s. 6d., 2s., and 1s., by Grocers, Chemists, and at Messrs. Spiers and Pond's Refreshment Rooms. Sole Agent and Consignee,

H. ESCHWEGE, 6 and 7 Coleman street, E.C.

LOEWENTHALS' NEWLY INVENTED AND REGISTERED

CHOCOLATINE

IS ACKNOWLEDGED BY THE BEST AUTHORITIES AS THE PUREST EXTRACT OF COCOA OBTAINABLE.

Vide—*British Medical Journal*, April 3rd; and other Medical Papers Sold in packets, 9d., 1s. 6d., 3s., and 6s. 6d. each.

N.B.—A sample *gratis* by enclosing a stamped envelope to the WHOLESALE DEPOT, 70 FENCHURCH STREET, London, E.C.

CADBURY'S COCOA ESSENCE

Absolutely genuine, economical, being about three times the strength of the Homœopathic Cocos and French Chocolates ordinarily sold; suitable for the weakest stomach, owing to two-thirds of the Fatty Matter, which forms 60 per cent. of the Nib, being removed. "The richness is thus overcome in a manner far preferable to the impoverishment of the Cocoa by dilution or Adulteration."—*The Lancet*. "Cocoa treated thus will, we expect, prove to be one of the most nutritious, digestible, and restorative of drinks."—*British Medical Journal*.

LIEBIG COMPANY'S EXTRACT OF MEAT.—PARIS EXHIBITION, 1867, TWO GOLD MEDALS: HAVRE EXHIBITION, 1868, THE GOLD MEDAL.—Only sort warranted perfect and genuine by BARON LIEBIG, the Inventor.—"A success and a boon."—*Medical Press and Circular*. One pint of delicious beef tea for 2½d., which costs 1s. if made from fresh Meat. Cheapest and finest flavoured "stock" for soups, &c.

CAUTION.—Require BARON LIEBIG'S signature upon every jar. Sold by all Italian Warehousemen, Grocers, Chemists, and Ship's Store Dealers. All Wholesale Houses; and of LIEBIG'S EXTRACT OF MEAT COMPANY (LIMITED), 43 Mark lane, E.C.

Notice.—Various chemical analyses have been published purporting to show a fraction more of moisture to exist in the Company's Extract than in some imitation sorts. It is extremely easy to evaporate the water almost to any extent, but it is quite as certain that the fine meaty flavour which distinguishes the Company's Extract from all others would be destroyed, if the concentration of the Extract were carried beyond a certain degree. Beef-tea made from Liebig Company's Extract with *boiling hot water* will be found to be greatly superior in flavour, strength and clearness to any other sort. This explains universal preference it obtains in the market.

This Extract is supplied to the British, French, Prussian, Russian, and other Governments.

AMSTERDAM EXHIBITION, 1869, GOLD MEDAL.

LIEBIG'S EXTRACT OF MEAT (GENUINE),

AS USED BY THE INDIA GOVERNMENT. This Extract, manufactured at Sydney, entirely from cattle of English breeds, is all analyzed by Dr. W. A. MILLER, F.R.S., who proves that this Extract is unsurpassed in composition. 2 oz., 1s. 9d.; 4 oz., 3s. 2d.; ½ lb., 6s.; 1 lb., 11s.; in Jars with Thompson's patent stoppers.

Insist on having Mr. TOOTH'S Manufacture. LIEBIG'S EXTRACT OF MUTTON. The attention of Medical Men is specially called to this Extract. LIEBIG'S EXTRACT OF MEAT BISCUITS (Coleman's Patent). Tins, 1s., 2s., and 3s. 9d. each. LIEBIG'S EXTRACT OF MEAT LOZENGES (Coleman's Patent), in Boxes, 1s., 2s. 6d., and 4s. 6d.

W. J. COLEMAN and CO., 13 St. Mary-at-Hill, London, E.C.

DIABETES.

BONTHRON'S DIABETIC BREAD AND BISCUITS

Have been approved by the Profession and by Diabetic Patients; contain no starchy matter, and are highly palatable and agreeable.

Country Orders punctually attended to.

Address, J. BONTHRON, 106, Regent-street, London, W

MOST IMPORTANT TO FAMILIES

GUINNESS'S XXX PORTER.—J. BEBE invites attention to this Celebrated Porter in Bottle, being now specially ordered to invalids, for its nutritive and strengthening qualities; in fact it has been found, in great many instances, to supersede Wine in recruiting health and strength. Each Bottle is wired and tin-foiled, and is protected by his label and "Trade Mark." Prices are as follows.

Guinness's Celebrated XXX Porter (small bottles) ..	2s. 4d.
Guinness's Celebrated XXX Porter (large do.) ..	4s. 6d.

Ten Vans deliver daily in the city and suburbs, and orders sent by Railway to all parts of Ireland.
JOHN BEBE, Rectifying Distiller, Direct Wine and Brandy Importer 18, THOMAS-STREET, DUBLIN.

SIR J. MURRAY'S

PURE FLUID MAGNESIA

IS RECOMMENDED BY PHYSICIANS SINCE 1807 for Bile, Acidities, and Indigestion. They also order his COR-DIAL CAMPHOR (3 grs. per ounce) as the best restorative for weak nerves or low fevers. His LEMON SYRUP, mixed with either Fluid, forms a brisk Aperient for any age—bottles 1s. and 2s. 6d. To guard against false liquids the Patentees' labels are subscribed "Sir J. MURRAY. Physician to the Lord Lieut."

HAMILTON, LONG, & CO'S

COD LIVER OIL of 1869.

THIS OIL, prepared by them since 1850, with the increasing approbation of the Profession and the Public, is extracted from the fresh Liver of the Channel Codfish, on their own Premises, and warranted perfectly pure.

H., L., and Co.'s ETHERISED COD LIVER OIL, now in general use, particularly suitable when the stomach is sensitive.

CLINICAL REMARKS ON CASES AT THE LONDON HOSPITAL.

By JOHN ADAMS, Surgeon.

A CASE OF ROUND SLOUGHING ULCER ABOVE THE PUBIS IN A MAN, AGED 54.

JUNE 4TH.—This man was admitted with a round deeply-excavated and sloughing sore, situated above the pubis. The history he gives of his case is, that a small red pimple was found by him about five months ago, that this was painful and itched very much, and, on being scratched, it discharged some matter. As the progress of the case was only observed by the man himself, it is useless to attempt any scientific description of it. I therefore pass on to describe the case as it first presented itself to us. The man was a pale thin person, of an unhealthy aspect, without any anxiety of countenance; from his history I could not ascertain that there was anything in his habits or mode of life likely to induce a sloughing sore in this region. It is true that he came from an unhealthy part of Whitechapel, a locality in which cholera had been rife during the late prevalence of that fatal epidemic. He had never had syphilis, and he had been able to afford himself such an amount of stimulus as was necessary for a healthy labourer. I confess I could not account for the disease.

The case is peculiar from the situation and the circular shape of the ulcer, and is an illustration of the tendency which sloughing ulcers have to assume a circular direction and to extend deeply. Thus, this ulcer began as a pimple, extended circumferentially as a slough, so as to occupy a diameter of two inches, and the depth of half an inch; its edges were defined and rather hard and somewhat inflamed, and the slough could not be detached from the rim of the ulcer by pulling it, nor could the slough be drawn up from the *fundus* of the ulcer or sore; and on pressing the edges of the ulcer a certain degree of

hardness was felt. I cannot say that the man's health was much affected.

What, then, is the character of this supra-pubic ulcer? Is it a specific ulcer? Is it a common sloughing ulcer? or is it a disease *sui generis*? or is it carbuncle? It is certainly not a common ulcer, for a common ulcer does not present this tendency to spread by sloughing in this circular direction. It is not cancer, because it wants the ordinary characters of cancer, and cancer rarely spreads by sloughing; and, if it does, the sloughing occurs in irregular masses of the cancerous deposit, rather than in the distinctly regular direction that this disease has assumed. There is no history to justify an opinion that the disease is syphilitic; nor is it of the character of those sloughing ulcers which are, distinctly phagædenic, and which often, if not always, originate in a syphilitic sore on the genitals, and commit most extensive ravages throughout the parts adjacent, and which in men lead to the entire destruction of the male organ, and in the female to the destruction of the labia externa and parts around. Of this latter disease, a few years ago many cases occurred in one of the very worst localities in London; the cases used to be known in the Borough Hospital as specimens of the *Swan alley disease*, and they afforded excellent examples of acute sloughing phagædena.

The disease under consideration is not quite like any of these, but it is to be regarded as a sloughing round ulcer, which I venture to call *supra-pubic*, as I have seen it attacking the supra-pubic region. The last case I saw was that of a gentleman in the City, in consultation with a surgeon now dead, but formerly an apprentice of this hospital. The disease was speedily arrested by appropriate treatment, which I will mention.

The treatment is comparatively simple. You must first dry the sore with a piece of lint well pressed in—the patient may be placed under chloroform if you please—and you take a glass brush, dip it into the strongest nitric acid, and apply it freely, first to the edges of the sore, especially where it has a tendency to spread, and then to the surface of the slough itself; and generally one application is sufficient; you then dress the sore with dry lint, and renew this every morning. I did this in the

case before you, but a poultice was applied without my sanction, but it did no harm.

At my next visit, four days after, the wound on a superficial view looked much as it did when I applied the acid; but a careful inspection showed that the sloughing had stopped, and that by pulling gently at the edge of the sore some slough could be detached. I therefore waited a few days more, and then detached a large quantity of slough, both at the margin and fundus of the ulcer. Three days after this, I succeeded in removing a still larger portion of the slough, and to-day the wound is nearly clean. The sore was dressed now with unguent. resinæ, and is cleansing gradually day by day.

During the progress of the case the patient has been sustained by wine and quinine, &c.

Rationale.—The employment of escharotics or stimulants in ulcers is very old, probably as old as Hippocrates, but no mention is made in the works of the Father of Medicine of the treatment of such cases as the present; but it is generally admitted in the present day by experienced surgeons that in all such cases it is worse than useless to waste time in using any other application than strong caustic, and of all caustics nitric acid is the best. Therefore, you had better at once adopt the plan I have recommended and used in this case: apply the strongest acid you can obtain, and you will not be disappointed. Let us endeavour to comprehend the use of the acid in cases like the present. You may say, what is the use of applying an escharotic to a part already dead? My idea of the action of the acid in these cases is this—and the same remarks apply to the use of the acid or caustic alkali, or any other chemical escharotic, in cases of boils and carbuncles—namely, the acid mixes with the fluids contained in the slough, penetrates the whole tissue of the slough, and coming in contact, diluted, by the fluids in the slough, with the diseased blood-vessels of the living structures underneath, stimulates them, probably coagulates the blood in them, and induces what is termed a healthy action, thus enabling them to separate themselves from the dead tissue, which, thus becoming loosened, is readily detached, or, as it is termed, *thrown off*. In my opinion, this is exactly what happens when the *potassa fusa* is applied to a carbuncle, and when you employ strong nitric acid to a simple boil, which I frequently do, with the delicate point of a glass rod.

I cannot speak too strongly of the efficacy of this treatment; it is in very constant use, and has often prevented the sloughing process from extending into large blood-vessels, which would in many cases lead to fatal hæmorrhage. It is, perhaps, idle to speculate on the action of the remedy—I mean as to the precise action of the acid on the living blood-vessels—it is enough to know its efficacy, so that we may put it in force at once when cases of this nature present themselves; rather than lose precious time in the employment of any other means of treatment. The acid has the effect, also, of preventing the extension of the gangrene in cases like the present—that is, where the gangrene spreads from some local cause—but it cannot have much beneficial influence in gangrene from constitutional causes. I cannot speak positively even on this subject; at any rate, its employment cannot do harm in any case of mortification, but I do not advise its application except in cases of gangrene like the present, and, as I have already stated, in carbuncle and other analogous diseases, as phagedæna, &c. I know of no situations where the acid may not be used in spreading gangrene; even over the surface of a bone it may be used. Thus, some of you must have seen it employed in almost every region in those terrific cases of hospital gangrene.

A slight re-application of the acid became requisite, and all sloughing ceased; but as the sore assumed an indolent character, I ordered the application of a solution of sulphate of copper, one grain to the ounce, and under this treatment the ulcer assumed a healthy appearance, and is now nearly healed.

ON MATERNAL IMPRESSIONS.

By J. WARING-CURRAN, L.K.Q.C.P.I., Sutton, Notts.

It can be readily understood how sudden shock experienced by the pregnant woman may affect the fetus in utero, by influencing the process and progress of development going on, and producing such deformities as hare-lip, cleft palate, *et hoc genus omne*, which are emblematic of imperfect or defective development; but the *modus operandi* of shock, in effecting those *maternal impressions* which so frequently take place, appears somewhat inexplicable and unaccountable. That from fright or mental shock an indelible stamp should be impressed upon the unborn child by nervous influence is, physiologically speaking, as singularly interesting as it is difficult to comprehend the nature of the agency which effects it. The nature of the law which so faithfully, yet inconsistently delineates and stamps upon the child an impression external and foreign to the laws which govern its development.

The result of my own observation is, that in no case does the sudden fright affect the fetus, that the so-called *lusus nature* is the consequence of progressive mental reflection and fear on the part of the mother; she mopes and broods over the shock she has sustained, or the fright she has received, and that, this continued, and in most cases unceasing reflection, eventually affects the embryo or fetus. A case to the point is this,—a woman told me she was struck in the face with a dead rabbit at the third month of her pregnancy; she quickly wiped with her apron the part of her face struck, and then rubbed her side with the same part of the apron. She felt that the child should be “marked,” but was thoroughly impressed with the notion that her presence of mind saved the face, and that the side would be the part affected. Upon the birth of the child a large nevus occupied the left side. We all know that in health, if we deliberately concentrate our attention or fix our ideas on any one organ, or part of our system, that the circulation of that organ or part will become preternaturally increased and abnormally affected. It is an undisputed fact that the most distinguished members of the medical profession—names which will be revered as long as the science of medicine exists—fell martyrs to those diseases upon which they had devoted most of their time, upon which they are still noted authorities; consequently, upon which they must have reflected, studied, and deliberated upon most. Can the force of reflection, the concentration of nervous influence, effect a morbid lesion upon the part or organ studied, or are the too numerous instances recorded mere coincidences or accidental occurrences? Be this as it may, the following cases go far to support my theory: in all of them the fetus was formed, in all of them it was not mere fright or shock and then forgetfulness; but in all of them the parent moped and brooded, and feared that her offspring should be deformed. The following cases came under my own immediate observation; they are illustrative of the fact that the shock was not forgotten, that nervous influence and the morbid nervous agency, though hastily engendered, was kept up until the hour of parturition arrived; that no amount of reasoning could divest the mother's mind from conclusions arrived at, and no amount of argument influence the so-called absurd notions that possessed her:—

CASE 1.—On the 24th of last August, I was hastily summoned to the wife of an inn-keeper. I was told she was flooding. Upon my arrival I found she had lost a considerable quantity of blood, and upon making an examination *per vaginam* (she had no labour pains), I found a leg clear of the external os. She was a primipara and thirty-four years of age, advanced to the eighth month of pregnancy; consequently I had little room for manipulating. Having waited a little time, and finding labour pains did not come on, nor even influenced by ergot which I administered, I delivered her of a still-born child, well-

developed, but small, and evidently dead some days. The hæmorrhage which continued necessitated the prompt removal of the placenta; upon introducing my hand for the purpose, I found a second child with its sternum against the os; this I turned and delivered by the feet. He lived a few minutes and then happily died, for upon looking at him my horror was great indeed. I completed the case and then turned my attention to the last born child (I should have remarked upon the birth of the first the mother inquired if it was "marked"). The body was well developed, but the head was black, the nose flat, the lips prominent, the hair covering the head curly and woolly, the discoloration of skin passed down over the chest and seemed to pass off obliquely across the upper part of the abdomen from left to right. The father of the child being one of the most respectable men in the town, I inquired into the circumstances of the case, and was informed in reply by the mother, that about the third month of her pregnancy, when engaged in the bar with her back to the door, hearing a strange voice behind her, she hastily turned round and saw a negro with his head and shoulders pushed through the bar window. She was so much terrified that she was unable to address him or inquire what he wanted. She "felt" that her child would be "marked," and her old lady friends said nothing to inspire confidence or dissipate the rash conclusion formed and rigidly adhered to, up to the time I delivered her.

CASE 2.—In the spring time of the year '68, a woman was passing through a meadow where a number of school-boys were at play—she had advanced to the sixth week, she considered, of pregnancy,—when one of the boys taking up a frog threatened to throw it at her; she begged of him not to do so, but he persisted, and struck her face with the frog. This produced an immediate feeling of sickness. She was obliged to sit down, and upon her return home compelled to go to bed and send for a doctor. She informed the gentleman who visited her that her child would resemble a frog. She appeared to suffer very much throughout her pregnancy; during the latter months she was unable to lie down, as she said she experienced something swimming in her inside; assuredly she was a great size. At the full period labour begun, and upon the rupture of the membranes the room-floor was literally deluged with the waters which escaped, the head presented and the child was quickly born. It gasped, as a fish drawn out of the water will for a few minutes, and died. The head in every particular resembled that of a frog, and the fingers were webbed, otherwise the monster was well formed. The woman had borne three children previously, and seemed a sensible person.

CASE 3.—In a neighbouring village, I was sent for two days ago, to attend a Mrs. A. in her confinement. It was a funis presentation, coming down by the side of the head, and as pulsation had ceased in it I waited the efforts of nature; the os was well dilated and a little infusion of ergot and borax brought in a couple of hours into the world the most hideous monster the eye could well dwell upon. There was double hare-lip, a cleft in the soft and hard palate, the nose was flat, and scarcely a square inch of face that was not covered with a soft hairy down; the occiput was on a level with the neck, and the hands and feet were deformed. Of course the monster was dead. I learned that Mrs. A. coming home from the market one Saturday afternoon, when ten weeks pregnant, was passing through a field when a hare closely pursued by a dog ran against her, and was killed by the dog at her very feet. To repeat her own expression, she said "she was done for," and fully expected bringing forth a deformed child.

CASE 4.—Is a married woman, whose child is under treatment for chronic hydrocephalus. Upon visiting the child repeatedly I remarked the mother's right hand and arm invariably bandaged up, and upon inquiring the nature of the injury or a description of her ailment, she exhibited for my inspection her arm, which she told me she never showed anyone. She is a native of this town,

and any one interested in the subject of *hairy nævus* will find this one of the most striking instances ever witnessed, if I except the woman a few weeks ago exhibited in London. The posterior part of the arm from the elbow to the wrist is covered with a sandy hair—the hair on the woman's head is quite black—fully an inch long, and very thickly set in a light brown hide or skin; the dorsal surface of the hand is also covered, except over the base of the thumb, with the same kind of integument and hair, the anterior surface of the arm is made up of a kind of soft fatty mass, from bend of elbow to wrist joint. It is impossible to find the flexor tendons through it; turning up the arm this soft mass hangs pendant and wrinkled for three inches from the bones by its own weight, the fingers are small and crooked, and the arm is almost useless to the woman. The only history I could gather was, that her mother when pregnant was frightened by a rat, and that as she grew the deformity increased. I have seen many cases of hairy nævus, but have never read of nor observed a parallel to this, the effect of a maternal impression.

I consider, then, that it is not the sudden shock to which these maternal impressions are to be attributed, but to the subsequent reflection upon the subject, and that in all similar cases it should be our first duty to disabuse, if possible, the woman's mind, and recommend change of scene and cheerful society.

I am indebted to Mr. Hanbury Bonser, of Kennington Park, for the histories of the two following cases, met with by him in practice when obstetric clerk to St. Thomas's Hospital, since writing the foregoing.

A. B., a married woman, in her seventh confinement, aged thirty-two years, was delivered, after the full term of gestation, by natural labour, of a well-developed, still-born child, whose appearance was very singular. The head was flattened from side to side, the body marked on one side with large dark-blue swellings, especially on the neck; the collar-bones were distorted and readily displaced, and the feet might be turned in any direction at the ankle-joints. In short, when generally viewed, it presented all the appearances of a child which had been run over.

The mother informed Mr. Hanbury Bonser, that in the fifth month of her pregnancy, one afternoon, she saw a little boy, whom she knew, run over in the street by a cab; she accompanied the child and his friends to St. Thomas's Hospital, where he was admitted. She was very much impressed with the disaster, and the injuries sustained—the crushing of the child's head, side, and feet, and felt that her unborn child would be marked from that time in some way.

C. D., æt. forty years, was delivered at the ninth month of utero-gestation, by natural labour, of a living female child, who appeared, *primâ facie*, quite healthy.

The child died in two days of hæmatemesis, having vomited a large quantity of blood during the first day of its birth.

An *autopsy* was made by Mr. Bonser. He found the stomach contained about two ounces of liquid blood, which, when tested, was found normal in character. The mucous membrane lining œsophagus, stomach, particularly at cardiac and pyloric orifices, small patches of duodenum, and a few inches of the ileum, were congested and punctured with points weeping blood. The lungs and other viscera were normal. During life the child had only a little milk, and to arrest hæmorrhage had prescribed three-drop doses of the tincture of perchloride of iron, in water.

The mother stated that, when applying for a card at the seventh month of pregnancy, she observed a young woman, who sat next her at the hospital, suddenly seized with a severe attack of hæmatemesis, who vomited at least a quart of blood. C. D. was removed by one of the officials, who remarked, "This is no sight for you." The occurrence made a deep impression on her mind, and she frequently expressed her belief that things would not turn out as they should.

Hospital Reports.

METROPOLITAN FREE HOSPITAL OF LONDON.

Cases under the care of DR. C. DRYSDALE
and MR. WARNER.

CASE 1.—A woman, aged thirty-five, the mother of four children, was seen in June, 1869, suffering from complete *procidencia uteri*. The case appeared to be one of those described by Huguier, under the name of supra-vaginal enlargement of the cervix uteri. The uterine sound entered more than four and a half inches into the uterus; but the visible cervix uteri was not enlarged. The patient was much incommoded in her work by the size of the prolapsed uterus, and begged that something might be done. No pessary of any moderate size had any effect in retaining the organ. It was, therefore, determined by Dr. Drysdale, that some operation of narrowing the vagina would be likely to afford relief. This was agreed to by Mr. Warner, who accordingly proceeded to perform the operation, the woman being under the influence of chloroform. The operation performed was as follows:—The uterus being prolapsed, Mr. Warner removed a strip of mucous membrane from the posterior wall of the vagina, about one inch broad at the level of the os uteri and tapering down towards the posterior outlet of the vagina. The edges of the denuded surface were then brought together by means of four silver interrupted sutures, and the patient was given fifteen minims of laudanum occasionally for some days. The case was very successful, and in three weeks the patient left hospital much more fit for her domestic duties, and with the uterus no longer in a state of prolapse at all.

CASE 2.—This was a curious instance of that not very uncommon condition of the vagina, described, we believe, first by Dr. Marion Sims, under the name of "*vaginismus*." The patient, a young woman, aged twenty-four, had been married some two years, and during this period had undergone much suffering from all attempts towards marital intercourse. On inspection there were seen to be numerous remains of the hymen, and the parts looked raw and inflamed around the orifice of the vagina, just at the insertion of that membrane. The patient was put under chloroform, and, according to the directions of Dr. Marion Sims, a complete circle of the hymen was removed. The result, as yet, has not been very satisfactory, as considerable *vaginismus* still exists.

CLINICAL RECORDS FROM THE DUBLIN HOSPITALS.

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.

MR. PORTER'S CLINIQUE.

Syme's Amputation through Condyles of Femur, for old-standing Disease of Knee-joint.

GEORGE W., *æt.* forty-three, a compositor by trade, was admitted into the Meath Hospital in September last, for the purpose of being relieved of a deformity, the result of old-standing disease of the cartilages of the right knee-joint. Thirty years before he had suffered from ulceration of the cartilages of this articulation, resulting in a dislocation of the tibia behind the femur, the limb being shortened to the extent of four inches, and the man, who suffered great pain in the joint at times, being precluded from following his occupation, owing to the difficulty of adapting an artificial support to the disabled limb.

By the patient's own desire, Mr. Porter, on September 20, removed the limb, selecting that amputation through

the condyles of the femur, which Mr. Syme has recommended, as the most suitable operation. A lunated incision was made across the front of the joint from condyle to condyle, on a level with the centre of the patella, the tissues divided down to the bone, and the flap being drawn up, the tendon of the quadriceps was divided. The point of the knife was entered at the outer angle of the wound, and, being passed behind the femur, was pushed out at the other end, and a flap about seven inches long cut from the calf of the leg. The condyles being then cleared from their connection with the soft parts, were sawn off; and, finally, five vessels having been ligatured, the flap was brought into position by sutures and strips of lint wet with cold water.

In his remarks to the class on this case, Mr. Porter called their attention to the fact that no dressing, save cold water, had been used, the wound had healed rapidly, and that now, three weeks after the operation, the man having recovered without a bad symptom, a most perfect stump resulted, which would allow the adaptation of an artificial limb, and render the man a much more useful member of society.

Different Methods of Operating for the cure of Anal Fistula.

On the same day Mr. Porter operated on two cases of fistula in ano, in each of which, with a view to instruct his class, he adopted a different method of procedure.

In the first case, that of a strong plethoric man, *æt.* fifty-five, who had a blind external fistula on each side of his anus, extending up beside the gut for nearly five inches, the operation adopted was carried out by means of a speculum devised by Sir Philip Crampton for the purpose. This speculum, which is made of silver, is sufficiently large to contain the index finger, and has a slit, about a quarter of an inch in width, extending along one side of it for nearly its whole length. The speculum being introduced, and the finger placed in it, a sharp-pointed bistoury is passed into the track of the fistula, and its end felt for by the index finger through the slit in the speculum. Having been found, the finger is withdrawn, and the point of the bistoury pushed through the wall of the gut and caught in the slit of the speculum. The knife is then made to cut its way to the surface with the usual sawing motion, the point being guarded by the speculum, in which it lies.

In the second case—that of a man, *æt.* thirty-three years, suffering from a blind external fistula on the right side of the gut, the track of the fistula was laid open into the rectum by means of Weiss's convertible fistula knife. The finger being introduced into the rectum, and the knife into the fistula, the end of the latter was felt for, and its sharp point being protruded, was pushed through into the gut; the lancet point was then drawn back, and the probe extremity of the knife being caught against the point of the finger was withdrawn in the usual way.

In both these cases the wounds were dressed from the bottom with plugs of lint, and the men made rapid and favourable recoveries.

Amputation of Penis for Epithelial Disease—Ricord's Operation.

Jas. B., *æt.* sixty, was admitted into the Meath Hospital, suffering from epithelial disease of the penis, of eight months' standing, involving a great part of the organ. The glands in the neighbourhood being free from enlargement, Mr. Porter, on the 6th of October, removed the part by operation, following Ricord's recommendation of slitting the mucous membrane of the urethra in four places, and stitching each part to the skin. Numerous ligatures were applied, but severe hæmorrhage commenced a few hours after the operation, and, refusing to yield to other treatment, it became necessary to pass three needles through the substance of the stump and employ *acupressure*. The needles and ligatures were removed in due time without further hæmorrhage, and the wound is now in a fair way to heal.

Transactions of Societies.

HUNTERIAN SOCIETY.

THE Hunterian Society of London held its first meeting of this Session on Wednesday evening last. Mr. Jonathan Hutchinson is President, which is a good guarantee for the character of the debates during the period of his office. After welcoming the members of the society on their return to work after the holiday season, Mr. Hutchinson vacated the chair, and read his paper on "Some of the Principal Diatheses and their Mutual Relations." Distinguishing diathesis from temperament and dyscrasia, the author enumerated some of the diatheses, such as the gouty, the syphilitic, the scrofulous, the cancerous, the atheromatous, the bronchocele diathesis, the darts, and others, which had, he remarked, several common properties. Firstly, in the diatheses, the cure of a person never seemed to be permanent, there was a similarity of cause and a similarity in the curative agents required in some, such as arsenic in many forms of darts affections. There was a tendency to hereditary disposition in these diseases, and the phenomenon of atavism was occasionally remarked on the diathesis. Do any diatheses require more than one life to produce them? What diatheses are remarked among the lower animals? Is it not probable that other diseased conditions of organs are connected with the more ordinary manifestations of skin eruptions, &c.? The author seems to suppose that all diatheses must have had an original cause, such as in syphilis the poison, in bronchocele the air and surroundings, in gout the alcoholic beverages, either of the patient or his progenitors. Wherever we find a peculiar disease the cause must be peculiar.

Having thus prepared the way, Mr. Hutchinson made some remarks on leprosy, which, he observed, is as constitutional a disease as is the tendency to tuberculosis. It is always the same disease in Norway, or wherever it is found. This disease is hereditary: but not affecting all the children. In Norway it is thought that hereditary transmission is its sole cause; but this is not so, as it is sometimes communicated by contact. Climate does not produce the disease alone, for it is found in the cold of Norway, as also in the West India islands. Dr. Bidentap, of Norway, ascribes it to some emanations, an untenable hypothesis. In Norway it was a noted fact that leprosy is only found on the west coast, and, above all, near the town of Bergen. It appears that the inhabitants of Norway eat enormously of fish, that is, those who live on the west coast among the fiords, and the fish they partake of is extremely coarse in many instances. The idea that the author had of the origin of leprosy was, then, that it was in some manner connected with the exclusive fish diet of some nations. This is why it is not found in this country, or even in Ireland, where so much poverty exists. There is not enough fish caught now-a-days to make it possible for the poor in this country to obtain it in sufficient quantities.

Certainly the paper by Mr. Hutchinson is pregnant with useful and practical ideas. If we could, when we see a patient, but think sometimes that his bronchitis, or his dyspepsia, was connected with a darts or a gouty diathesis, it is clear that we should often be able to think of some remedy which otherwise might not have suggested itself to our mind.

Literature.

* The conclusion of our Special Report on Students' Text Books is unavoidably postponed till next week.

Works on Medicine, Surgery, and Midwifery, form the subject of the next part. Copies for review should be sent without delay.

REPORT OF THE METROPOLITAN BOARD OF WORKS, 1868-9.*

THIS is a most important pamphlet, and contains some points which must prove of interest to the medical enquirer.

* Waterlow and Sons, pp. 116.

In the first place, we find that the cost of the main drainage works up to this time has been £4,128,000; with exception of portions of the main line, it has been in operation for the last four years. The uncompleted sewer is the low level line on the north side of the river, portions of which have been delayed, in consequence of having to be formed in connection with the Thames Embankment, between Westminster Bridge and Blackfriars, and also with the embankment at Chelsea. The deaths, it appears, in the metropolis, especially in the low-lying districts, have been fewer since the execution of the main drainage works than in previous years, and in districts which are lower than the level of the river at high water, the contents of the sewers used formerly to stagnate during a large portion of each day. The fish, too, have greatly increased in the purified river. It appears that the company which had intended conveying the sewage from Barking Creek to Maplin on the Essex coast has fallen through. The ventilation of the sewers, it seems, is still imperfect. With regard to the Northern Thames Embankment, provision has been made for the formation of a roadway, 64 feet wide, throughout the entire length of the embankment, from Westminster to Blackfriars, with two foot-ways of sixteen feet wide on the river side and on the land side; but these alterations have all been kept back by the slow progress made by the railway works. The new street from Blackfriars to the Mansion House is a continuation of the embankment road, and will be seventy feet wide, and 3,450 feet in length.

The open spaces of the metropolis are of great importance to the student of hygiene. And first of all comes Hampstead Heath. It appears that the suit in Chancery, instituted by certain of the freeholders and copyholders of the manor, to restrain the Lord from building upon, and otherwise prejudicially interfering with the Heath without regard to their rights has not yet been brought to a final decision. It is hoped, however, that the new Lord of the Manor may not be so stubborn as the late Sir T. M. Wilson.

The Reports speak of the Municipal Corporations Bill, which recommended, as our readers may remember, the division of the giant metropolis into ten divisions, each of which was to be presided over by its Mayor and Council, in this following the example of the Arrondissements of Paris. The Board says that, after careful consideration of the subject, it arrived at the conclusion that the Municipal Corporations Bill was not calculated to improve the government of the metropolis. We are not inclined to agree with this decision of the Board, and hope that they may reconsider it; although, perhaps, we could not expect that a measure which would probably interfere with their own existence would be likely to prove acceptable to the body.

With regard to the Contagious Diseases (Animals) Bill, this provides similar provisions to that of 1866 and 1867; but, in addition, it provides that malarious, infectious, or contagious diseases shall include pleuro-pneumonia, foot-and-mouth disease, sheep pox, sheep scab, and glanders. The provisions of this Bill are approved of by the Board.

The improvements of the Chelsea Embankment, and the proposed improvement in Park Lane, are to be paid for out of the proceeds of the coal and wine duties. The Secretary of the Treasury has recently introduced a Bill empowering the Board to raise all loans by means of a Metropolitan Consolidated Stock, the security for which would be the whole rateable property of the metropolis, about nineteen millions.

It appears that last year the Fire Brigade attended with their engines, &c., at 1,585 fires. The chimney fires occurring during this period have been 2,130. The Board remarks that there is some little difficulty in knowing where water for extinguishing these fires is to be obtained, since the Company's turncocks alone know where the plugs are. The proceedings in Parliament in 1863 resulted in the passing of the City of London Gas Act, which has done much good to consumers.

The South Metropolitan Gas Company applied for power to raise £375,000 capital, and proposed that their dividends should be limited to 10 per cent., and that the price of gas should be 3s. 6d. per 1,000 feet, and the illuminating power 14 candles. With these remarks we must conclude our notice of this important Report.

—
TURKISH CUISINE.—The *Gazette de France* states that among the dishes composing the bill of fare of the dinner given by the Sultan to the Empress of the French on the evening of her arrival at Constantinople was one composed entirely of the brains of ostriches.

A MEDICAL TRIP TO PARIS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

PARIS, AUGUST 21, 1869.

SIR,—In a former letter, dated the 20th of August, I endeavoured to make known to you the admirable site and construction of the hospital for scrofula at Berk-sur-Mer. With your permission, I will now relate a few of my experiences during a week's stay in Paris. One of my first visits to Parisian hospitals was to the Hôpital du Midi, the male venereal hospital, where I found that great changes had taken place. In the first place, the service of that hospital is now performed by two physicians, Drs. Simonet and Charles Mauriac, and one surgeon, M. Liegois, instead of, as formerly, by three surgeons, or two surgeons and one physician. I have long thought that this was a change that ought to be made in the interests of science. In former days in Paris, and still in London, surgeons alone were supposed to pay attention to syphilis, and you know that our Lock Hospital is still entirely under the care of surgical gentlemen. This is, in my opinion, the chief reason why the knowledge of these diseases has progressed so slowly. Had syphilis been, as it certainly ought long ere this, considered as rather the province of the physician than the surgeon (for comparatively few and slight surgical operations are ever required at the early part of this disease), we should not have been only now at the commencement of the subject, and so deficient in knowledge of the specific diseases of the liver, the kidneys, the brain, and the lungs and their treatment. Let us hope that the Lock Hospital may soon imitate the good example of the Parisians, and appoint physicians to its next vacancies. The Midi Hospital for male venereal cases contains 300 beds, always full, I believe. At the "consultation," or out-patient department, about 100 cases attend daily, except Sunday; and all severe cases, such as orchitis, or bubo, or secondary syphilis, are immediately received into hospital, if there is room, and entirely at the option of the medical man, and (thank goodness!) without anything to do with those detestable "Governors" who make such a parade of their charity in this metropolis; but who, as you know, *cher confrère*, have their prejudices and their pet complaints and *protégés*, whom we must attend to, *volens volens*. And, of course, in a country like ours, long afflicted with the malady of puritanism, venereal diseases are not admitted into almost any of our hospitals; and thus our unfortunate male, and, above all, female citizens, when *poor*, and affected with such diseases, are, as I am sure you know as well as I, often most truly *unfortunate*.

In my first visit to the Hôpital du Midi, I saw in the wards of Dr. Charles Mauriac a most well-marked case of double synovitis of the knee-joint, distinctly gonorrhoeal in its character. The man had suffered from the complaint thrice. As some among our ingenious brethren here seem to wish to cast doubt on the existence of gonorrhoeal rheumatism (I think Mr. Skey is among the number), I can only say that this one case would, I think, have made them believe in the reality of the disease for the rest of their life. Among the details of practice observed by me at the Midi, I saw that Dr. Mauriac was in the habit, in almost all cases, of using blisters, or iodine paint, to endeavour to stop the onward progress of suppurating buboes, and, apparently, with considerable success. His application to soft sores was invariably the solid stick of nitrate of silver, and this, with the tincture of iodine, he also applied to chancreous buboes when they would open, notwithstanding the application of blisters. Well, you will ask, how did he treat syphilis? To this I reply, that M. Mauriac is a mercurialist, and that the same formulae as were made use of in the days of the illustrious M. Ricord still remain in vogue at the Midi at present. Here is the formula of the pill still used at the Midi for syphilis—"1st. To take morning and evening, fasting, one of the following pills:—Protoiodide of mercury, '003 centigrammes, (about gr. $\frac{1}{4}$); extract of quinia, '006 centigrammes; extract of opium, '001 centigrammes; to make a pill, of which make 60. 2nd. Avoid all excess and all fatigue; substantial diet." All this is written in French, not in dog-Latin, as we do. Another favourite mercurial prescription with Cullerier was as follows:—"1st. To take morning and evening, fasting, in half a glass of sugar-water, and to which are added some drops of orange-flower essence, a tablespoonful of the following mixture, viz., liquor of Van Swieten (a solution of perchloride of mercury), 500 grammes. 2nd. Avoid all excess and all fatigue, and take substantial diet." Lastly, in order to give our friends the mercurialists a choice of their weapons, is added

the following:—"1st. To make, morning and evening, on the internal aspect of each thigh, above the knee, inunction with the size of a hazel nut of the following ointment:—Neapolitan ointment, 60 grammes (*i.e.*, unguentum hydrargyri), and cover the parts anointed with a flannel compress. 2nd. Avoid all fatigue, and eat well." Some mercurialists have a taste for their favourite drug in all stages of syphilis, so, to suit them, the following prescription is among the *armamenta*:—"1st. To take at night, on going to bed, a tablespoonful of the following mixture:—Binioidide of mercury, '025 centigrammes (about gr. iv.); iodide of potassium, 25 grammes (about 3 $\frac{1}{4}$); syrup of saponiaire, 500 grammes (about 16 ounces). (This gives about gr. 1-6th of the binioidide, and gr. x. of the iodide of potassium as a dose)." All of these prescriptions are, as perhaps you know, disliked by myself and the non-mercurial school; but the following prescription is employed by all of us, as well as by the staff of the Midi, in tertiary lesions:—"1st. To take, morning and evening, a tablespoonful of the following solution, in a cup of infusion of saponiaire, viz., iodide of potassium, 30 grammes to water a litre" (about gr. vijs. to each dose). I must not omit to say, that the treatment of the initial lesion of syphilis has the following consecrated to it:—"1st. To take every two days, for a week, fasting, in the morning, a litre of infusion of herbs, in which shall be dissolved one of the following, sulphate of magnesia, 90 grammes (*i.e.*, 3iij) divided into three parts. 2nd. Smear the parts affected morning and evening with the size of a hazel nut of the following pomade:—Neapolitan ointment, 30 grammes (*i.e.*, mercurial ointment); extract of belladonna, 6 grammes (3iss.); and cover them entirely with cataplasms of linseed meal. 3rd. Every two days, an entire bath, of one hour's duration. 4th. Avoid all excess and fatigue, sober diet and absolute rest of the organ."

I have now, I think, exhausted the list of prescriptions for that formidable disease, syphilis; but, perhaps, some of your readers may wish to know how they treat chancres at the Midi, I mean soft suppurating sores. Well, the first of these prescriptions is as follows:—"Dress the affected part three or four times daily with lint, soaked in the following solution:—Nitrate of silver, one gramme; distilled water, 20 grammes." The next prescription is as follows:—"1st. Powder thrice a day the affected parts with a pinch of the following powder:—Iodoform finely powdered, 3 grammes; having washed them first with fresh water; avoid all excess and fatigue, and keep the parts quite at rest." The next prescription for soft chancre is:—"1st. Dress thrice daily the affected parts with lint smeared with the following ointment:—Ceratum opii, 20 grammes; calomel, 10 grammes." The next prescription is, I presume, for chancres beneath the prepuce, it is:—"Make four times a day an injection between the prepuce and gland with the following solution:—Nitrate of silver, 2 grammes; distilled water, 60 grammes. Take a bath every two days." The last prescription for chancre is as follows:—"Dress, seven or eight times a day, the affected parts with lint dipped in water, in which one of the following is dissolved:—Chlorate of potash, 40 grammes (3i., 3iiss.); divide into four parts."

Such is the present treatment of syphilis, and its ally, soft chancre, at the Midi, as practised by Dr. Simonet and Dr. Mauriac; but, I must add, that the surgeon, M. Liegois, is not content with inunction, perchloride mixture, or iodide of mercury pills, but seems to prefer entirely the use of subcutaneous injection in all his syphilitic patients. And, I daresay, he does as well with mercury in that form as his *confrères* with their formula, *i.e.*, I suspect all of them do a great deal of harm to their patients by administering this enfeebling drug; but I intend returning to this subject again, when I speak of the Lourcine, so at present I will try to explain how they treat gonorrhœa or *blenorragia* at the Midi in the male. The first prescription I shall mention is as follows:—"1st. To take, for a week, a litre of infusion of herbs in which are dissolved the contents of one of the following papers:—Sulphate of magnesia, 90 grammes (3iij.), divide into three parts. 2nd. Cover entirely and constantly the parts with a linseed meal poultice. 3rd. A bath every two days. 4th. Sober diet; avoid all excess and fatigue, and absolute rest of the affected organ." The staff of the Midi seem still much enamoured of copaiba, notwithstanding the writings of Graves, Sir H. Thompson, and Weeden Cooke. Hence, the following is constantly ordered:—"1st. To take, morning and evening, fasting, the size of a walnut of the following: cubeb powder and copaiba equal parts, 100 grammes, or as much as may be required to make a paste easily divided into pieces. 2nd. Drink as little as possible, diet

sober. No pure wine, liquors, or beer. Avoid all fatigue, and use a suspensory bandage; keep the affected part quite in repose." Here is another prescription frequently ordered:—"1st. Take on three occasions during the day, from fifteen to eighteen soft capsules of copaiiba. 2nd. Drink as little as possible, abstain from pure wine, liquors, or beer. Avoid all fatigue, and use a suspensory bandage." Another prescription commands the patient—"1st, to drink each day a litre of decoction of dandelion roots, in which are to be dissolved one of the following:—Nitrate of potash, 10 grammes, divide into five parts. 2nd. Every day a complete bath of an hour in duration. 3rd. Abstain from pure wines, liquors, and beer. Avoid all fatigue, and wear a suspensory bandage; absolute rest of the affected organ." Here is another:—"1st. To drink every day five to six glasses of tar water. 2nd. To take on these occasions, and fasting, during the course of the day fifteen soft capsules of turpentine. 3rd. Diet light, mingled with one-third of wine, and two-thirds of water, in a litre of which one of the following is to be mixed:—Bicarbonate of soda, 10 grammes, divide into five parts. 4th. Dress warmly, and avoid excess and all fatigue. Use enemata to keep the bowels open." The following is a list of the injections for clap:—"To make three injections daily with the following liquid:—Rose water, 200 grammes (3viss.); alum, tannin, equal parts, .050 centigrammes (gr. 8); red wine, 50 grammes (3iss.)." The next is—"To make, three times daily, an injection with the following:—Rose water, 100 grammes (3üj.), sulphate of zinc, acetate of lead, equal parts, 50 centigrammes (gr. viii.); extract of rhatany, laudanum, aa. 1 gramme (gr. xv.). 2. Sober diet, abstain from pure wine, beer, and liquors. Avoid all fatigue, and wear a suspensory bandage. Absolute repose of the affected part." Such are the chief prescriptions of the Hôpital du Midi, that classical ground of the great Ricord and his celebrated school. I must not omit to add that each physician attends daily from half past eight till ten or eleven A.M., and receives,—(would you believe it, Mr. Editor?), is actually paid for his services,—1,500 francs a year. Of course, we shall never receive anything from our immaculate Governors in London. Here a physician is supposed to be too much of an aristocrat to care for payment for his services. Truly, as Sterne says, "They do these things better in France." As I walked homeward with Dr. Mauriac through the charming Jardins du Luxembourg, he informed me that he had just translated the work of Dr. West, on Diseases of Women, into French. I said I believed that it was the very best work in the English language on this difficult subject, with the addition, perhaps, of that by Dr. G. Hewitt. Dr. Mauriac is of the school of MM. Nonat, Bernutz, and Aran, that is, he is much opposed to the heroic surgical practices of Dr. Marion Sims, and those gentlemen who are constantly splitting up the cervix uteri, or doing something to it with the knife. He thinks that the key to uterine pathology is inflammation, in which I heartily concur with my learned *confrère*. I mentioned to him that there has recently been some grave debate on the question as to the effect upon the health of the female of the almost universal domestic habits made use of in Paris, in order to avoid adding to the responsibilities of an already sufficiently numerous offspring. M. Mauriac said that he had noticed this fact in a remark made by Dr. West in his work; and that he believed that the idea was absurdly exaggerated, since, he continued, by far the greatest part of the diseases of the uterus are consequent upon the inflammation which follow pregnancy and parturition.

He added that he had thought of making a note to that effect in his translation of West. M. Mauriac confessed himself to be a convert to Malthusian principles—"Here is," said he, "the way in which I look at the question. In a new country, like America, a rapid increase of population is useful; but in Europe what is wanted is the wellbeing and development of each individual, not any increase in population." I need not, perhaps, say that I heartily agreed in this with my respected *confrère*. M. Mauriac stated that the ordinary method used by the French families for restraining their numbers was, as I had thought, a very simple one. And it is clearly a matter for grave debate, whether the well-being of the Parisian population, as a whole so evidently superior, I humbly believe, to that of the London population, is not cheaply purchased by the slight self-denial required, and if the practices of Paris, if disagreeable, are not at any rate less distressing than the infanticide said to be common in London, the starvation of Ireland, or the dangerous practices of our American relatives. By the way, I see that at the British Association meeting, some of our well-meaning but rather violent brethren, have lately been pretending to believe that the Dialectical Mal-

thusians did not refer, in their celebrated debate, to the small-family system of the French. This is, truly, a feeble invention of anti-Malthusians. Let such gentlemen learn that we should always take the best parts of our adversaries' case, and try to attack that. You don't take Sebastopol by demolishing some mud-hut, but by taking the Malakoff. Now, the Malthusian Malakoff is the fact that the French don't increase in numbers their poor are better off on the whole than our poor; they do not emigrate, and yet don't grumble so much as our pseudo-philanthropists of the violent, or anti-Mill and Malthus school. Listen to the words addressed by a distinguished Frenchman, Maire of Amiens in 1832, M. Charles Dunoyer, in a letter to J. Garnier (*J. Garnier, sur la Population, Paris, 1857, p. 95*) on the question of casuistry, too!

"It is incredible, that the action of calling beings into life, that, without doubt, of all human actions the most important in its consequences, should be precisely the one which persons have the least felt the necessity of regulating, or have regulated the worst. It is true that the fashion, of the civil act and the sacrament has been arranged; but persons have desired that the consequences of marriage should be left, so to speak, to the will of God. The sole rule prescribed has been, that it is necessary either to abstain from all conjugal approaches, or to omit nothing which might render the union prolific. So long as the married pair may believe that they do not commit a vain act, the morality of the casuists finds nothing to reproach them with; let them be wanting in care for themselves, let them ill-treat one another, and, above all, let them dispense with all care for the absent, and perhaps unfortunate, third party, whom they are about to call into existence without caring for the lot which awaits him,—all is of little consequence; the essential is, that they should avoid doing a vain act. Such is the morality of the casuists, a morality in contradiction to all morality of common sense; for what good sense and morality require is not, assuredly, that we should abstain from vain acts, but that we abstain from injurious acts." M. Joseph Garnier (p. 93) adds, "It is because they have remained strangers to the researches and studies concerning population, which have recently enlightened and rectified the morality of the casuists, that the modern Doctors of the Church still spread abroad, especially at the Confessional, advice opposed to the sense of families and to the interests of population. Thus is sold at Paris, chez Pousielgue-Rusand, bookseller of the clergy, a book entitled 'Mæchologie, a Treatise on the Sins against the Sixth and Ninth Commandments of the Decalogue, &c.' by Debreynne, with this indication, between parentheses, 'It is exclusively destined for the clergy.' The author says he is a physician, professor, priest, and brother of La Trappe; it is a collection of doctrines and counsels, in French and Latin, directed against conjugal prudence, which the confessor is enjoined to represent to his penitents as the most damnable of mortal sins."

In a work before me, entitled "Rapports Conjugaux," by Dr. Alexander Mayer, Baillièrre, Paris, 1857, I find in the Preface, p. 5, "We had proposed to ourselves to stigmatize a vice deeply rooted in our manners, to such a degree that one may affirm almost—and I put this restriction from pure condescension—that very few families are exempt from it. We do not exempt even those where virtue is hereditary, or where religious sentiments have preserved their empire. We confound in our affirmation all classes of society, except those which are debased by misery and despair." If such be the case, it would appear that the ghostly confessors of France do not find a very obedient set of penitents. It is in Ireland, alas! that they must look for devout believers in their erroneous doctrines, not in enlightened France or Paris, and, when the iniquitous land customs of Ireland shall be altered, as probably they will soon be, the peasantry of that long-suffering country will soon learn to repel such silly advice, and, perchance, teach the Catholic priesthood that they must, like Chalmers, Whately, and other divines, learn to distinguish utility as the true basis of morality, instead of sentiment. Were the works of Mr. Mill on political economy and on morals but well known in Paris, I think that poverty would soon be an affair of the past. Meanwhile, there is not in Paris such a blind superstition in favour of "quivers full of them," &c., as we find on our side of the Channel; and the French population, on the whole, as you know, may be said to be stationary. Indeed, they do not seem in Paris to me to be far from the day when the saying of Mr. J. S. Mill may be considered a truism:—"Little advance can be expected in morality, until the producing of a large family is looked upon in the same way as drunkenness, or any other

physical excess; but, while the aristocracy and clergy are foremost in setting an example of this species of incontinence, what can we expect from the poor?"—"Political Economy, People's Edition," book ii., chap. xiii.

EXTERN MATERNITIES AND LYING-IN HOSPITALS.

A REPLY TO CRITICISMS ON A COMMUNICATION TO THE DUBLIN OBSTETRICAL SOCIETY.

By EVORY KENNEDY, M.D., F.K.Q.C.P.

(Continued from page 308.)

MR. PRESIDENT, you have thought it your duty, whilst in occupation of the chair of this Society, to throw yourself into this debate, as you have a perfect right to do; but whilst in dealing out criticism as a member of this Society, you must recollect that you have stepped down to the level of your competitors. You, Sir, like them, must be satisfied, therefore, to accept such retort to your observations as they seem to require at my hands. Before dealing with your criticism, Sir, you will permit me respectfully to refer to certain preliminary observations made by you in answer to my remonstrance upon the highly inconvenient, if not objectionable, manner of conducting this debate. I already declared that my object in producing my paper at this Society, in place of simply publishing it, was to secure full discussion. But, Sir, "Il est a des fagots et des fagots." Can you for a moment imagine that I ever contemplated that I should have been called upon to sit out—I thank you for the word—the "crambe repetita" objections of fourteen speakers of written treatises, each extending to an unlimited period of time, some to an hour and a half, and one "horresco referens" to one hour and forty minutes? Can it be supposed that in my most sanguine aspirations for fame, I could ever have anticipated that the rules which bind all societies of limiting the speakers in a debate to reasonable and practicable allowance of time should have been totally disregarded in this instance? And that I should have been martyred to the extent I have been, and obliged to sit out in silence the same, I shall not call them futile objections or platitudes; but the freedom of debate enables me to denominate them as the same erroneous statements, the same unworthy imputations iterated and reiterated, "iterum iterumque," by fourteen learned but verbose doctors.

No, Sir, such a trial was beyond human endurance, and I remonstrated, but alas without effect, and I was eventually obliged to discontinue my attendance. If the Council of your Society determined upon adopting such a system of *discussion*, if so you designate the preparation and utterance of fourteen elaborate papers in answer to my one, they should, at least, have informed me of their intention as well as the fourteen learned doctors, and I should have well considered whether I should have submitted myself to such an infliction. Does any gentleman mean to tell me that he would have gone through these fifteen papers, my own included, in his own study, were he a free will agent, and not caught in such a trap as I was? I therefore maintain, Sir, that I was justified in remonstrating, as I did, against the novel system of debate by bill and answer of unlimited length, adopted especially in my case, and that I was not only justified in doing so, but as the founder of this Society, in warning you, that although it may survive one such *irregularity*—that is your own language, Sir, not mine, and a very appropriate word it was—although, as I said, it may survive one such *irregularity*, repetitions would prove its destruction.

Sir, I regret to be obliged to state that, exactly upon the

same grounds, I have felt it my duty to abstain from noticing all those gentlemen who have commented on the few observations made upon treatment in my paper: I feel constrained to abstain from noticing any observation in that branch of your criticisms.

Respect for the Society over which you preside, and regard for yourself, have determined me not to apply the same rule to your other criticisms.

We shall therefore, with your permission, pass to the second point, as you term it, in which you put the word "pest-houses" into my mouth as applied again to the great lying-in hospitals. Sir, I tell you the word is yours, not mine. And sitting as you do in *quasi* judgment in that chair, it is a serious thing for you to use such language lightly, to whomsoever imputed. Be careful, Sir, I beseech you, how you repeat such a phrase. These epithets stick. I am the more induced to offer you this advice, unasked, from your conveying to me that you are still open to conviction, and not a member of that overwhelming "organization" alluded to by the naughty press, "got up to stifle free discussion on a great sanitary question." I admire your defence of the speakers upon one side of this question. It is worthy of all praise, the breaking a lance with the all-powerful press, if done in the right way. But, Sir, I confess I think you, the chairman of this Society, whose duty it was to secure free discussion, and to act the even-handed judge upon the occasion, ought, at least, to defend the Society at large, and not merely one side of it engaged in a discussion. And you must excuse me, as a well-wisher to the Society, when I say you have gone further by your defence to convict the Society, or a portion of it, of the charge brought against it, than all the straightforward criticism of the press has done. Sir, it may appear ungracious my being thus explicit upon this subject, more especially when my eye is attracted a little lower in your paper to the graceful words applied to me, in which you conclude your remarks upon the criticism of the press.

Sir, much as I feel obliged and gratified at your good opinion, you cannot misunderstand me when I say I decline to accept a compliment, paid even by you, to my self-apparent objects and motives at the expense of my judgment, my discretion, capacity, and duty.

But, Sir, let us deal briefly with your reasoning upon my figures. These you call in question by a general denial as regards the Dublin Lying-in Hospital, without any grounds, and by a special denial as regards the Coombe Hospital, of which you have been for twenty-eight years physician, upon the following grounds.

"You deny my calculation that 3 out of 4 die in the Coombe Lying-in Hospital "that should not," or in other words, from "preventable causes," and say certainly my calculation cannot be based on the return made to me of the Coombe Hospital for the last seven years; and you add that the tabular statement subsequently furnished by Dr. Kidd in no wise corroborates it. Now, with Dr. Kidd's, or any subsequent returns or with how they may vary or how affect the death-rates I have nothing to do. I have only to deal with the authentic paper upon which I based my calculations, furnished me by the Registrar of the Coombe Hospital. This places the death-rate of the Coombe Hospital for the last 7 years at 1 in 72.25. Now, Sir, the mean of the three small hospitals with which the Coombe were compared, gave a death-rate of 1 in 282.7. Four times 72 make 288, therefore if one in 282.7 was taken as the basis of our calculation of the average proportion of inevitable deaths in labour, we were justified in treating this great sanitary question, to state that 3 out of 4 of the deaths that occurred in the Coombe were unnecessary, in other words, if only one constituted the necessary or inevitable proportion of deaths *ceteris paribus*, that the 3 others were in excess evitable and consequently unnecessary, and if this be

so, you, Sir, by a parity of reasoning were not justified in your special denial.

You will, Sir, I trust, excuse my declining to take in detail your explanation or ideas showing why the deaths should be taken, in the case of the Coombe, out of the general category, or admitting that your cases, many of which, in all likelihood, died of metria, should be classed under different heads, and not metria. The forceps may be used, version may be necessary; that dire necessity—craniotomy, or cephalotripsy may occur, and yet it is but too familiar to us to know that all these cases may die of metria. Thereupon the three pages in which you have amplified upon the distinctions of the state that led, possibly to metria, in its different modifications, is not germane to our discussion. In entering upon this inquiry I distinctly disclaimed attempting to base my calculations upon the numbers of cases of metria. I found the difficulties of arriving at what was metria so great that I determined to rest upon the general mortality as the only true basis of calculation. It is a very simple matter for you, Sir, or any other inquirer, to arrive at your own conclusions upon the proportions of metria and accidents in childbirth, but as it has nothing to do with the calculation at issue, I must simply reiterate that Dr. Ringland has failed to shake my statement, based on the authority of his own registrar's return of the Coombe death-rate for the seven years furnished to me, which leaves me no alternative but to arrive at the conclusion that 3 out of 4 evitable deaths occur in the Coombe Lying-in Hospital.

With Dr. Ringland's third point I quite agree. He says, and saves me much trouble by saying manfully, when dealing with the alteration of our hospitals, to prevent contagion—"I believe the true prevention is isolation." Had he stopped here I would have accepted his opinion as conclusive and valuable, but unfortunately he adds—"instant and complete isolation of the infected from the healthy." That is, he is satisfied that the true prevention is isolation, but he would not insist upon this until probably the mischief was done. But he corroborates this opinion by begging the question as to the time contagion develops itself, which he has fixed at some convenient season after the attack that admits of the removal of the patient: yet, on the other hand, you have Dr. M'Clintock and others assuring you that the attack sets in at any period, and spreads at the earliest period after, or almost simultaneous with, its own commencement; and you have me, as well as Dr. Stokes and others, telling you that it occurs before delivery.

What becomes, then, of the statement that "contagion does not exist in the incipience of the attack?" Sir, it does not require to prove even this, as the fact is, in the cases where the disease shows itself, it don't require immediate contact. The poison pervades the hospital. The hospital is its habitat, and be the patient removed or not the taint spreads, when it generates, haunts, and destroys. You, Mr. President, give us one crumb of comfort in the debate. You, like Dr. Kidd, announce, and speak with confidence of a plan to be adopted in the Coombe Hospital, in future, of keeping an isolated building, entered by a separate stair, for metria patients, to be removed to when attacked. I accept this announcement as that of a step in the right direction. But I could have wished you had been able to announce a step farther, and that isolation in its true sense had been determined upon in your new structure.

I may mention, before passing from this subject, that a very valuable testimony is afforded on the subject of isolation in a report furnished by Dr. Graily Hewitt, of the British Lying-in Hospital, in which he remarks:—"During the early part of the year 1862, and before I had taken, in conjunction with Dr. Murray, charge of the in-patients of the hospital, several patients were the subject of puerperal fever, and four of them died; two others were discharged in a very weak state; and

the hospital was for a time closed. As soon after taking charge of the in-patients as circumstances admitted, steps were taken by Dr. Murray and myself to isolate the patients to a greater extent than before. The number of beds in each ward was reduced from six to four, and the communication between the wards as much as possible cut off."

Let us now see what was the result of the partial approximation to isolation, for Dr. Hewitt does not lead us to suppose it was quite perfect. The mortality in the four years previously, in which time there were 428 deliveries, amounted to 7, that is, to 1 in 61; whereas in the next four years there were 10 deaths in 761 deliveries, which was only 1 in 75, and this although the number of deliveries was nearly doubled. This calculation I look upon, therefore, as extremely valuable, as showing the advantage to be gained by even an approximation to isolation, whilst it also shows the check to the benefit that would in all likelihood have been derived from it had not the crowding on admission of an increased number of patients counteracted the advantage of the attempt at isolation. It is thus very valuable in showing that partial and not complete isolation will only disappoint our expectations of preventing the disease.

(To be continued.)

FRACTURE OF THE SCAPULA.

E. E. Coleman, M.D., of St. Louis, Mo., contributes the following case to the *Med. Archives*, June, 1869:—

On December 19, 1867, I was called to see Mrs. P., æt. 53, of delicate frame and nervous temperament, who, while stooping, in the act of making a fire, was struck on the shoulder with such force by a piece of plaster falling from the ceiling, as to prostrate her on the floor, from which she was unable to rise, until assisted by her children, by whom she was placed in bed, where, on my arrival, I found her in a very excited condition, and complaining of excruciating pain whenever she attempted to move.

On examination I found, with much contusion of the soft parts, a fracture of the body of the scapula, extending through the spine, about an inch and a half from its lower extremity, for which I applied the usual dressing, in such cases, of compress and roller around the chest, and fixing the arm so as to immobilize the parts. The case progressed satisfactorily for several weeks, when the bandages causing such excoriation of the axilla as to necessitate a different form of dressing, I contrived an appliance which, upon trial, I found to obviate the inconveniences of the roller, while it met all the indications, and was much more simple. This consisted merely of a form of "waist," made of three thicknesses of muslin, to give it firmness and strength, and laced over each shoulder, and under the arm of the side opposite the injury, in such manner as to make it fit perfectly tight by lacing. This, as stated, answered an admirable purpose; she could wear it with comfort; in a few days its effects were well marked, and the case progressed favourably until a firm bony union was secured. I have since used the same appliance for fractures of the ribs, and found it equally efficacious. I also exhibited a specimen of it before the Medico-Chirurgical Society, of this city, the members of which were favourably impressed with it, and expressed their determination to use it.

But an interesting phase of the case now commences. From the long continued immobility of the parts there was a false or partial ankylosis of both the shoulder and elbow joints. This I endeavoured to overcome by passive motion, and, even under the influence of chloroform, with but partial success. She was unable to straighten the arm, and was barely able to get the hand to her head by carrying the arm forward. She was unable to elevate the elbow in a line with the body, and an effort to raise it by force caused her much pain. On the 10th of April, 1869, while coming down stairs, she missed her footing, and fell a distance of thirteen steps of eight inches rise each. In her efforts to save the affected side, she instinctively threw out her arms, and received the force of the fall on the opposite side. Of course she was considerably jarred by the fall, somewhat bruised, and no little frightened. I was sent for immediately, and being apprised of the nature of her fall before I left my office, expected to find some serious injury, possibly a re-fracture of the same scapula. Before I arrived,

she herself had made up her mind for another six months' suffering. But, upon examination, I not only found that she had received no fracture, but that she had recovered *complete* use of her "lame arm." Her accident had accomplished, in a moment, that which I had unsuccessfully attempted for fourteen months. Except from the few contusions she had received, no pain or inconvenience followed.

WEDNESDAY, OCTOBER 20, 1869.

UNPAID SERVICES OF MEDICAL MEN.

THERE seems to be a tendency at present to endeavour to redress some of the wrongs under which the Medical Profession have long patiently groaned. One degree for all is demanded, in order to save the amount of trouble and expense incident on the numerous titles we are obliged to purchase by our toil and funds. Examinations instead of lectures are demanded. A representation of the Profession in its own Council is another movement towards better days for the Profession. And we believe that the time has now come also when medical men have come into such a position that they are enabled to make some head against the trades-unionism of the rest of society, and that they are now determined that their means of earning a subsistence shall not be wrested from them by pretences of charity, without some protest on their part. The amount of medical charities in London now-a-days is enormous; and we are not saying a bit too much when we express it to be our belief that these charities are doing great harm to the cause of even medical science, by their being so frequently officered by gentlemen who give their time and experience gratis. The labour of the unpaid may often be of the first class, when we meet with the rare combination of an active mind co-existing at the same time with an independent pocket. There are, doubtless, numerous exceptions to the law which says that when a workman *has* no interest in his business, he cannot *take* much interest in it. There are in Medicine, as in the Church, devoted men, who, like the ascetic followers of all religions, are only anxious to do

good, at all cost to their own comfort, and think no self-sacrifice too great to promote the happiness of the masses. But such a set of men are the great exception to the general rule. Men desire, usually, in pursuing their professions, to gain by them food, clothing, and other necessaries, besides that *consideration* which Voltaire so amusingly depicts as causing men to do so many foolish things, and suffer so much pain.

The Profession is now gradually, in London at least, getting tired of doing all the disagreeable work of attending to the most unfortunate and miserable of the poorer classes, in order to listen at the end of the year, at a bad dinner, to some trashy talk among the enlightened members of the Common Council, or other Governors, who are usually long-winded and detestably illiterate, and yet exceedingly fond of being praised and praising each other after dinner at some of these charities. We have usually noticed at such post-prandial exhibitions that the "Medical Officers" is a toast which is given at the *fad* end of everything, as a matter of but little consequence, after the usual loyal and patriotic toasts, the health of the Lord Mayor, the Aldermen, &c., had worn out the enthusiasm and destroyed the eloquence of the guests. But as to medical men getting any honorarium for attending hospitals or dispensaries, of course, this has been an unheard of idea. Oliver Twist asking for more is the picture we may have in our mind as to the treatment such extraordinary demands would be likely to call forth from the committees of our dispensaries, unless we are *alive to our own interests*. Fortunately, there has recently been a considerable difficulty experienced by the committees of the various dispensaries in obtaining new physicians and surgeons to fill up the vacancies in their honorary staff. And, hence, what would vainly have been demanded from any sense of justice, is now becoming wrung from Governors by the best of all means, *viz.*, necessity. A few of the London Dispensaries have been honourable exceptions to the mass of these *charitable* institutions, and have been in the habit of rewarding their medical men by a small gratuity at the end of the year. Thus, the Bloomsbury Dispensary, in Great Russell street, which has annually 4,000 patients, and an income of £800, gives £105 a year to one physician, and the same to a surgeon; the London Dispensary, Church street, Spitalfields, has 3,000 patients, £400 income, and gives two physicians £45 each, and one surgeon the same; the Eastern Dispensary, Lemn street, Whitechapel, has 4,250 patients, an income of £800 to £1000, it has one physician and one surgeon, who divide between them £132; the Finsbury Dispensary, Woodbridge-st., Clerkenwell, has 22,000 attendance, an income of £500, and gives two physicians each £40, and one surgeon the same; the Surrey Dispensary, Great Dover street, Southwark, has 5,000 patients, an income of £1,300, and pays four physicians £42 each, and two surgeons an equal sum; the Tower Hamlets, the St. Paul's, and St. Barnabas Dispensaries also pay their physicians and surgeons, and only quite recently, the Royal General Dispensary, in St. Bartholomew's Close, has been obliged, after long advertising in vain for honorary officers, to give each of its staff £40 a year. We hear that the Farringdon General Dispensary is also about to do something similar. Of course, in all these cases, the existing medical staff have been retained, and sometimes no new appointments have been needed. We have no hesitation in urging our brethren to try to make this an universal custom in all

our hospitals and dispensaries, wherever there is no medical school, indirectly to give some remuneration for their labour. Even as a question of morality we urge it strongly. There can be no doubt that the tendency of doing a great deal of work gratis is to diminish the care, and sometimes to lower the interest the physician or surgeon ought to take in *every case* he sees. What tales do we not hear of seeing a case every forty seconds in many of our charities? In Paris there is scarcely any gratuitous public medical charity. Some there are, of course, as in the case of M. Langlebert's special clinique, and this we do not wish to see altered. Specialists may sometimes require a place where they wish to see a number of one class of cases, and this may, indirectly, be advantageous to them and to the Profession, by making them able practitioners of a particular branch; but the present system of wholesale unpaid medical services in our smaller general hospitals and dispensaries has not this excuse. It is simply a means of defrauding the whole Profession out of all the small fees that would otherwise reach it, without any, or almost any, counterbalancing advantage that we can clearly see.

ARMY SURGEONS—THEIR DUTIES AND GRIEVANCES.

"WITHOUT branches the vine yields no fruit." Such is the purport of one of the oldest known proverbs; and to nothing can it with more propriety be applied than to an army. The actual thews and sinews of war—that is, our battalions—may be compared to the stem; but in order that they may yield actual fruit, or, in other words, effectually perform the functions for which they are maintained, the co-operation of several branches or *departments* is required. Thus, in order that men may fight, they require to be fed, clothed, armed, supplied with ammunition, provided with shelter, have sufficient means of transport, and last, but not least, be preserved in the highest possible state of physical fitness for undergoing fatigue and the harassing duties inseparable from their occupation. It is with reference to the last of these requirements, and of the officers concerned in the important duties connected with it, that we would now offer a few remarks. To the members of the medical department are entrusted the responsible duties of selecting for the ranks of the army human material, sound in body and mind, and of rejecting such as would, if passed, only serve to impair the efficiency of the general machine; to them the country looks for the proper treatment of her soldiers when stricken whether by the enemy or by the far more dangerous, because ever present, endemic diseases of the countries wherein they are sent to serve; to them, in times of war, we look not only for sufficient professional and other attendance on all who, by wounds or sickness, become non-effective, but also for the selection of suitable shelter; and to them commanders naturally look for reliable estimates of the amount and nature of transport required for their conveyance, for approximately correct views in regard to the rate of loss by sickness, in order that reinforcements may be applied for in such time as to maintain the numerical strength of the force; to them also the commanders and their country look for devising means by which, under the varying conditions of military science, the health of armies may be best preserved, and the ravages of epidemics, when unfortu-

nately they occur, reduced to a minimum. Nor must we forget that to them, under many conditions of military science, not only soldiers and their wives, but officers and their families, have to trust entirely for professional aid.

There are numerous other duties than those just enumerated which fall to the medical officers of the army, but the list is already sufficient to indicate some measure of the importance which attaches to this "branch" of the service, and it becomes apparent that the measure of efficiency with which the department is administered, must have a most important bearing upon the success or failure of military expeditions.

Unfortunately, this discovery had not been made in all its fulness at the commencement of the Crimean war. Long before the end of that expedition, however, the vast importance of an efficient body of medical men to an army had, through sheer force of circumstances, made itself apparent to all who were interested in the success of our forces. The committee which subsequently investigated the arrangements made in reference to that expedition, recorded in very decided terms how highly they estimated efficient medical services, and, acting upon their views, the late Lord Herbert set himself to work to place that department upon a more improved footing to what up to that time had been accorded to it. Soon afterwards the China war occurred, to test the efficiency of the department in its improved state, then the war in New Zealand, and, more recently the expedition to Abyssinia; and the published records of each and all of these indicate the high estimate in which officers in command held the services of the department, while, if we revert to the period of the Indian mutiny, the military despatches contain many acknowledgments of how greatly they were indebted to their medical officers.

The importance of this branch of the service being such as we have indicated, it becomes a question really of national concern, in what manner, with due regard to economy, it can be maintained in the highest state of efficiency, and, unfortunately, there exist at the present time, not a few indications that the condition into which it is drifting is likely at no distant time, unless checked, to bring it to what may be called a dead lock. Let us, therefore, briefly indicate some of the measures which we deem likely to bring about the required improvements.

We willingly acknowledge that, as compared with bygone times, much care has been taken to ensure the appointment of highly qualified candidates, and to afford them special training for their particular duties. We question, however, whether the success of these measures has been equal to the anticipations regarding them, and whether, notwithstanding the improvements of late years made in pay and retiring allowances, the inducements are sufficient to encourage the better class of young professional men to enter the service, or those who are now in it to exert their talents as they should. Thus, in respect to rewards, honorary and otherwise, medical officers are, we think, unfairly kept at a disadvantage, both as compared to their professional brethren in civil life and as compared to their brother officers of the military branches of the service; and we submit that this state of matters should be rectified. On the score of promotion, the medical department is placed at a material disadvantage as compared to other non-purchase corps in many ways; one of which is that there appears now to be no limit to the period during which the officers holding the highest rank

are permitted to serve in their grade, short of their reaching the patriarchal age of five years under the allotted span of human existence. Why, let us ask, should Inspectors-General not be forced to retire after, say, three or five years in their grade?—General, and other staff officers are so. The rule holds good in the Indian Medical Service, and was rigidly observed in the Army prior to 1858, a similar proviso having apparently been omitted by an oversight in the Warrant of December of that year. Is it said that such a regulation would be attended by considerable increase in the allowance granted under the head of non-effective services? We believe that, on the contrary, an actual saving in this item of the Budget would accrue, as surgeons-major and junior deputies-inspector, instead of quitting the service in which they saw no prospect of further advancement, as they have already done, and will do in still greater numbers, would be induced to serve on in the hope of succeeding to some of the vacancies upon which they could calculate to occur at stated periods.

Promotion by selection, although theoretically excellent, has in practice been found to have its seamy side. Distinguished services or merit should always be rewarded, but in a manner to inflict the minimum of injury upon the less fortunate officers; thus, honorary distinctions and brevets might be given as they are to what are termed the *executive* branches. Steps in the ordinary course should, as a rule, among the administrative grades, be given according to seniority. From the executive to the administrative grades a certain degree of selection is doubtless necessary, although the occasion very rarely occurs. Let the officer in either case, who is deemed ineligible for advancement, be placed upon the retired list, and thus avoid the chagrin of being superseded. A man who is passed over seldom works cheerfully or efficiently afterwards.

In the next place, army surgeons complain, and with justice, that while little inducement for exertion is held out in the service for them, they are at a disadvantage as compared with those of what are called the "executive" ranks in obtaining appointments in civil life; thus, whereas a captain, colonel, or general is eligible for any appointment, from the governorship of a colony to that of a gaol, medical officers are virtually debarred from every appointment, save and except that very invidious one of charge of a military prison. This is not as it should be. There are many appointments for which the training of military medical men especially fits them; for it must be allowed that they are at least taught not only to form their opinions on subjects that come before them, but to express, and often defend, those opinions. Among the positions for which we consider them to be in a special manner fitted are those connected with inspections and supervision under the Poor-law, the inspections of lunatic asylums, the sanitary administration of towns, and many others; while we consider that no others than medical officers retired from the army should be employed in connection with the Militia.

Were it made a condition that candidates for employment in either of these capacities had spent a certain number of years in the army, and were in possession of certificates from their professional and military superiors, not only would additional zeal be imparted to them while serving, but their retirement, with or without pension according to their length of service, would create vacancies for which, we venture to predict, there would be a keen competition among highly trained candidates.

Notes on Current Topics.

Diseased Meat.

At a meeting of the Public Health Committee of the Corporation of Dublin held on the 8th inst., Dr. Cameron, the City Analyst, in reporting that 10,000 pounds weight of diseased meat had been seized and condemned in Dublin during the month of August, made the following remarks:—

"There are certain diseases of the animals used as food which render their flesh unwholesome and sometimes poisonous. The more important of these diseases affecting the ox are contagious pleuro-pneumonia, or lung distemper; foot and mouth disease, or *epizootic aphtha*; the different forms of carbuncular fever—anthrax, blackleg, &c., and dropsical affections. Sheep suffer from blackleg, *variola ovina*, or small pox, anthrax, splenic apoplexy or "braxy." The pig is liable to various forms of carbuncular fever, and suffers from hog cholera (also called the *soldier*, from the red colour of the animal's skin), a kind of typhoid fever. Oxen, sheep, and swine become diseased from the presence of small animals, termed entozoa (internal parasites), within their bodies. The measles of the pig is the larva, or immature form of the tape worm, and is termed *Cysticercus cellulosus*. The "rot" in sheep is produced by a little animal, a kind of "flake" (*Distoma hepatica*), in the animal's liver, where hundreds of these parasites are often found. Another parasite takes up its abode in the sheep's brain, and develops the fatal disease termed "sturdy" or "gid." A small worm termed *Trichina spiralis* occurs occasionally in the muscles of the pig, and it has been found in many other species of animals.

That perfectly fresh meat, not obviously diseased, may yet possess poisonous properties has been repeatedly proved. Dr. Kesteven mentions a case where twelve persons were poisoned by eating pork which was neither putrid nor even of (apparently) bad quality. He shows that the poisonous qualities of the flesh must have been the result of disease which had affected the living animal. Dr. Letheby, the Medical Officer of Health for London, states that in 1860 no fewer than 63 persons were poisoned by the flesh of a cow that had been killed whilst suffering from lung distemper. One of the cases terminated fatally, and the cause of death was clearly established before a jury. At Newtownards, County of Down, three years ago, two persons died and several others suffered considerably after partaking of veal not *obviously* diseased, and in which chemical analysis could detect no poison. Dr. Livingstone states that when the natives of Africa use the flesh of oxen affected with pleuro-pneumonia, they suffer from carbuncular fever; and the Registrar-General of England remarks in one of his reports that since the introduction of the lung distemper of cattle into England the deaths of human beings from carbuncles, and similar diseases, are greatly increased.

The flesh of sheep affected with small-pox produces, says Dr. Parkes (Manual of Hygiene, page 194, third edition, 1869), "sickness and diarrhoea and sometimes febrile symptoms." The Belgian Academy of Medicine inquired into the results of eating the flesh of animals affected with "blackleg," and they came to the conclusion that such flesh was unwholesome. The Government of Belgium, therefore, interdicted the sale of carcasses of animals affected with that disease.

Large numbers of persons have lost their lives in consequence of eating flesh containing parasites. In Iceland 20 per cent. of the deaths among the population are caused by the ravages of a parasite derived from the sheep and other of the lower animals.

The tapeworm (*Tenia solium*) which affects mankind is derived from the measles worm of the pig, and another kind of tapeworm (*Tenia mediocanellata*) is derived from the flesh of the ox.

Indian Native Midwives.

DR. CORBYN, the Civil Surgeon of Bareilly, in his report to the Inspector of Dispensaries for the year 1867, gives an account of the establishment of a school for educating native females in midwifery. There are few medical officers in India who have not witnessed most horrible and fatal scenes from the ignorance and infatuation of the present class of "Dhais;" the movement, therefore, is an enlightened one and well worthy of extension. At a meeting of the committee of the Charitable Dispensary, a wealthy banker of the city, Lalla Luchmi Narain, read a paper, setting forth the great evil and mortality that resulted in all classes of female society from the ignorance and prejudice of their midwives, and the need that was felt of trained and educated nurses, and he went so far as to state as a fact that any respectable native would rather let his wife, sister, or mother, die than permit her to be examined by any one of the opposite sex.

Medical and Hospital Reforms.

MR. SIMON'S speech at the Medical Teachers' Association appears to be at length bearing fruits. Dr. Hearne, of Southampton, seems to have taken up the question warmly, and, as we ourselves have sometimes said, he seems to think that, in respect to the attainment of medical qualifications, all the existing restrictions should be removed, and, the examinations being made thoroughly searching and effective in their character, it should be immaterial how or in what particular sphere the knowledge of the candidates presenting themselves is obtained. The *Lancet* seems rather to favour this idea, and although we confess ourselves to be in favour of certificates of attendance on practical dissections and hospital practice, we must say we agree with the writers on that side, that the attendance on lectures now obligatory is an absurdity and a bore, unless the student finds it a good way of learning, which it often is not.

With regard to the large hospital system, we have expressed our conviction before, that Sir J. Y. Simpson's views are the correct ones. For instance, taking the mortality attendant on parturition among poor patients, he states that of 888,303 delivered in hospitals, 30,394 died, or 1 in 29; while of 934,781 delivered at home, 4,405 died, or 1 in 212. What need have we of more than this to prove the dangers of large hospitals for the sick? If there be need, let us say that of 618 cases of amputation of the leg in country practice 13 per cent. only died; whilst 44 per cent. of 613 cases in hospital practice succumbed. Cottage hospitals, then, such as that for consumption at Ventnor in the Isle of Wight, are what are now pointed out by the observations of Simpson and others.

Fever at Chippenham.

A PERTINENT letter on the outbreak of fever at Chippenham appears in the *Devizes Gazette*. The writer, referring to the death of a very intelligent and valuable member of our profession resident in Chippenham, Dr. Wm. Henry Colborne, says:—

"Not long ago the death of Peter Awdry, Esq., of the same town, was recorded in your columns. Both these gentlemen owe their death to typhoid fever, of which disease Chippenham has been for some time, and now is, the chosen seat. It is true that not very many deaths may have taken place from this disease in Chippenham; had many deaths occurred we should probably have heard quite as much about this pretty town as we heard not long since about Guildford and some other localities. It is, however, sufficient to know that a medical authority in Chippenham during Dr. Colborne's late illness voluntarily proffered to show Dr. Colborne's medical attendants *twenty or thirty* cases of typhoid fever in Chippenham! The unobserved poor man may die and be buried, and the exigencies of life in his circle may soon cause the bitterness of his loss to be benumbed; but when men like the late Mr. Peter Awdry and the late Dr. Colborne are struck down in the middle of a useful and honourable career, depriving the community of intelligent and active members, perhaps the town may be unwillingly drawn to reflection. There can be no doubt that Chippenham is a focus of fever—and must be cleansed. Corporations and Town Commissioners may quarrel and wrangle as they will; but bad drainage, bad sewerage, and the prevalence of diphtheria and fever must not be allowed to exist while human means are available to control or arrest their deadly course. There are those in the Corporation and among the Town Commissioners who know what ought to be done; *their* course is clear; let them combine and represent the state of the town to the Medical Officer of the Privy Council, and the disgraceful condition of Chippenham in a sanitary point of view will soon be corrected. It is a gross offence against Christianity, against morality, against social order and common decency, that in a town like Chippenham sanitary measures should be so neglected that a medical man should be able to say he could point to *twenty or thirty cases of fever* IN ONE DAY."

Poor-Law Medical Officers' Association.

THE quarterly meeting of this Association will be held this day, at the Freemasons' Tavern, at half-past seven o'clock, p.m. After the Report of the Council has been submitted, the President, Dr. Rogers, will state his experience of the working of the Irish dispensary system, acquired in a recent visit to Ireland for the purpose. We understand that the Council will be happy to see medical officers (whether members or not), and guardians who are desirous of obtaining information on the subject, and we therefore hope to witness a large attendance.

Anti-Vaccinating Madness.

THE anti-vaccination maniacs have taken to blasphemy. A handbill has been distributed in Sheffield from which we quote our proof of this:—

"The Mark of the Beast!" "And I beheld another beast coming out of the earth; and he had two horns like a lamb, and he spake as a dragon. . . . And he deceiveth them that dwell on the earth. . . . And he caused all, both small and great, rich and poor, free and bond, to receive a mark on their right hand (arm?) or on their foreheads. . . . And the first angel went and poured out his vial upon the earth; and there fell a noisome and grievous sore upon the men which had the

mark of the beast." "Vaccination is a sin, a delusion, and a snare; spreads broadcast through the land scrofula, syp hilis, consumption, and all other hereditary diseases; does not, as proved by experience, prevent small-pox; costs the country over 250,000*l.* per year, and is the chief cause of that fearful infant mortality which carries to the grave half the children born in Sheffield before the age of five years." "Is it not rank blasphemy for poor, erring human nature to assert that when God created man in His own image, He left the work of His hands—which He pronounced good—imperfect until Jenner's so-called discovery, as asserted by the vaccinators? Is it not the height of impiousness to tamper with the Creator's chiefest work, by wickedly inserting into the pure blood of the healthy babe poisonous corruption cast out from the body of the diseased brute?"

Such ravings as this might well be mistaken for the production of one of those lunatics who in some asylums have taken to writing. The anti-vaccinators have long made themselves ridiculous; but their noise has drawn upon them some notice. After the above the quiet contempt of respectable citizens may possibly extinguish them.

Copper as a Cure for Cholera.

DR. BURG, in a work on the prophylactic and curative influence of copper in cases of cholera, quotes a report made by M. Vernois to the Council of Hygiene and Sanitation of the Seine, on the immunity of Parisian copper workers during the cholera epidemic of 1865-66.

The entire number of these workmen, comprising a population of 37,000, only presented 29 cases of cholera, a proportion of 1 in 1,270.

The author institutes a comparison between them and the workers in iron and steel, who had 202 cases of cholera in a population of 28,000, that is to say, 1 in 209.

Lastly, in a population of 7,500 workers in other metals than copper, iron, or steel, 42 cases occurred, making a proportion of 1 in 178.

It is worthy of remark, that during the terrible epidemic of 1832, the numerous population of nightmen, dustmen, and knackers of Paris and Montfaucon furnished no victim to the epidemic.

Charing-Cross Hospital.

WE learn from the *Medical Times* that this Hospital has at last succeeded in finding a physician for its skin department. Dr. Beigel is the fortunate person; but as we have heard that he was also a candidate on the former occasion, it is to be presumed that the desperate advertisements of the Governors have not procured them any additional choice. The only thing the public will be concerned about is, whether Dr. Beigel has been required to give up all his other appointments "*within a month,*" as was so harshly insisted on in the case on which we have several times commented. If so, the Hospital Governors are to be congratulated on having obtained so much more than they deserved to secure the exclusive services of so respectable and able a physician as Dr. Beigel has proved since his residence in this country. We wish that gentleman may find the position he has accepted prove satisfactory to him. He might have easily found a more liberal governing body to which to transfer the good work he has long been doing as physician to other charities. It is to be hoped that the fact of having obtained some one to take charge of the department will not make the govern-

ing body less sensitive to their position. They should not forget that, after unusually extensive advertising, they are obliged to fall back upon a gentleman who was previously a candidate, and to appoint him legally they must alter their bye-laws.

Nursery Reform.

ANY one who takes a turn in the Park in the hours that are given up by the fashionable to children and their nurses may easily convince himself of the carelessness and neglect, if not absolute cruelty, of the guardians of the little ones. Genteel mothers pay good wages for their nurses, but little know to whom they commit their darlings. We are certain that what these children need is the care of some *gentlewoman*, and not a few such would find situations of this kind far better than the overstocked governess market. What more appropriate employment for ladies than the care of children? For this reason we heartily wish success to a scheme started by a lady correspondent of the *Times*, under the signature of "*Mater.*" The plan was taken up by Miss Heath, the head of the Home and Foreign Governess Institute (148 Brompton Road). The scheme is said to have already contributed to the comfort of some gentlewomen, and we hope it may extend its benefits to thousands of others.

Clinical Examinations at the Queen's University.

AT the examinations for the medical and surgical degrees of the Queen's University, held last week, the candidates were examined upon the cases of patients in the South Workhouse Hospital, Dublin. The Examiners—Dr. Mapother, and Prof. Cuming, of Belfast—obtained the permission of the medical officers and the Board of Guardians. We understand that the plan worked well, and that the answering was satisfactory, although a very short notice was given. Other licensing bodies in Ireland are likely to adopt this practical mode of examination.

The Tactics of the Vaccinomaniacs.

IN a matter which would appear to affect the interests and views of the Profession medical journals must necessarily address the public under the suspicion of bias. For this reason the medical press is comparatively powerless for many objects which it is best qualified to deal with, which is yet much more tellingly treated by extra professional periodicals. It is a satisfaction to us, therefore, to see the Anti-Vaccination movement shown to the public in its true light of folly and wilful falsity in the *Daily News*. Plain facts and homely speaking are the most convincing eloquence in such a matter, and we transfer, with pleasure, to our columns excerpts from the article.

"That any doubt should be thrown upon the value of Jenner's famous discovery after it has been accepted throughout Europe, is indeed astonishing. Upon inquiry, however, it appears that for some time there has been a league established for the special purpose of counteracting one of the wisest acts of the Legislature in connection with public health. The Anti-Compulsory Vaccination League is not to be blamed for fairly advocating its own views, but it incurs a serious responsibility when it appeals to ignorant prejudice. A handbill, which is dated Sheffield, Feb. 5, 1869, and is signed by the hon. secretary of the

Anti-Compulsory Vaccination Committee, begins with this side heading:—'The Mark of the Beast!'—'Vaccination is a sin, a delusion, and a snare; spreads broadcast through the land, scrofula, syphilis, consumption, and all other hereditary diseases; does not, as proved by experience, prevent small-pox; costs the country over £250,000 per year, and is the chief cause of that fearful infant mortality which carries to the grave half the children born in Sheffield before the age of five years.'

"It would be scarcely worth while to notice such stuff as this were it not necessary to expose the ingenious manner in which the society endeavours to charge the large number of deaths in Sheffield in 1863, and again in 1867-8, upon vaccination; whilst the health return proves that the plague actually arose through the refusal of mothers to take their children to the vaccinators. In the year 1867-8 especially, a very severe epidemic of this formidable disease broke out in Sheffield and other places, and as a matter of course found out those who were unprotected. The consequence was that 468 young persons died from small-pox. That the vaccine matter has the power of transmitting syphilis is a simple untruth. Mr. Tomkins, the Inspector of Vaccinations of the National Vaccine Establishment, who has himself vaccinated 50,000 children, has never seen syphilis produced by vaccination. In addition to this personal experience he has had for thirty years a knowledge of the results of the operations of the establishment, and in no case has such a result happened. In order to put the question to the severest of all tests, syphilitic persons have been vaccinated, and the lymph taken from their arms transmitted to others, without the slightest ill effect arising. The experiment has been tried over and over again by medical men of all nations, and the absolute impossibility of transmitting any infection with the vaccine lymph established. That consumption or scrofula is so transmissible is absurd. It would be as intelligible to say a Roman nose could be passed on by the lancet. If any sore should arise, or any scrofulous ulcer break out in the young children after they have been vaccinated, it is put down as a consequence instead of a sequence. If the public were aware of the amount of scrofula and skin disease prevalent among the poor, they would know how to value the evidence upon which mothers are now and then led to resist the obligations of the law. That the act of vaccination, and the disturbance it sets up in the constitution, may lead to the production of slight forms of skin disease is acknowledged to be an open question by those skilled in the art, and it is just possible that the irruption on the child that was presented to Mr. Vaughan at Bow-street the other day by its mother, arose from this cause, but that it had nothing to do with the impurity of the vaccine matter was proved by the fact that the child from whom the vaccine lymph was produced was perfectly healthy, and continues so.

"Whilst it was at the option of parents whether they would have their children vaccinated or not, the discovery of Jenner was practically worthless as regards the poorer classes of the community; their children were left as a rule unprotected, and a prey to the first outbreak of the epidemic, when they formed centres of infection which intensified the disease. The pauper funeral expenses, thus designedly brought about, only form one part of the evil of this ignorant disregard of vaccination. In violent epidemics even a certain percentage of the vaccinated are liable to a recurrence of the disease. Thus the provident

are placed at the mercy of the ignorant and careless. What would be thought of a man who refused to have his house insured at the public expense, and determined to pull down his party wall, totally regardless of the interests of his neighbours?

"In order that the public may be acquainted with the true value of vaccination, when thoroughly carried out, we may refer to the statistics of the army on this head. Every soldier and sailor is now protected against small-pox, and the effect is an exemption from the disease, which contrasts most favourably with that of the civil population, which, as we have shown, is now and then rudely seized by epidemics of small-pox, in exact proportion as the clamour of the Anti-Vaccination League has been rife in particular neighbourhoods. If we take the army returns of death from small-pox since their first publication in 1859 to 1864, and lump the six years together, we find that the ratio per 10,000 of strength only yielded 0·84 deaths—or less than one per cent., whilst among the sailors of the Royal Navy, it was less during the same period than two per 10,000. We are told indeed that it is in the nature of epidemics to 'wear themselves out,' and in this manner the wonderful immunity of those protected by vaccination is accounted for by the Anti-Vaccination League. But the answer to this is the violence with which the disease, with unerring aim, seizes and slaughters the young unprotected children whose mothers have taken up the cry urged against vaccination by this very society. Witness the epidemics in Carnarvon and Sheffield in 1857; that again of Carmarthen in 1858, and of York in 1862, when the slaughtered innocents had never been touched by the lancet of the vaccinator."

Death from Bichloride of Methyline.

On Friday evening Mr. Langham held an inquest at Charing-cross Hospital, on Mr. Charles Verner, aged 39, an actor of some repute, long connected with the London theatres, who died the preceding Monday in the hospital. Mrs. Verner said deceased was her husband. He had been an in-patient of the hospital for the last three months, labouring under a disease of the jaw. His sufferings were of the most acute character. It was at the joint request of herself and the deceased that the operation was to be performed. The medical gentlemen of the hospital had informed both herself and the deceased that the operation might afford a chance of saving her husband's life, but it was only a faint chance. They were made fully aware of the danger attending the operation, but were prepared to have it done at all hazards, the sufferings of deceased were so great. All that had been done was with the full consent of the deceased, and also with her consent.—Mr. Edwin Canton, surgeon to the hospital, said the deceased had been under his care for several weeks past, suffering from a malignant disease of the upper jawbone. It was a disease likely to prove fatal, and from the progress made by the disease, the death of the deceased must have occurred in a few weeks. He suggested that an operation should be performed, with the very faint hope of a cure, at the same time informing the deceased and his wife of the great danger attending it, but they replied they should wish it to be performed at all risks. The witness here handed in a paper to the coroner, which he stated was in the handwriting of the deceased, and on which was written, "I, Charles Verner,

give my free consent to the operation upon me being performed by Mr. Canton, and will bear all the risks."—The anæsthetic used in the hospital was bichloride of methylene, and on the present occasion was diluted with air to make it less powerful. Every care had been taken to prepare the deceased for the operation. The bichloride was administered in his presence, and that of several of his colleagues, by Mr. Peter Marshall, the regular chloroformist of the hospital, and was skilfully and properly administered. Within two minutes of its being administered the patient fell back and died. The galvanic apparatus and all other appliances used in cases of this kind were at once resorted to, but life was extinct. No attempt had been made to perform the operation. The Coroner said he had felt it his duty, in the interest of the hospital, to make this inquiry, and in his opinion the result clearly proved that it was one of those occurrences which no human agency could prevent. Every care appeared to have been taken, and all that had been done was with the full knowledge of the deceased and his wife. The jury returned a verdict accordingly.

Removal of the Dead.

DR. TRIPE, the medical officer of health for the parish of Hackney, applied for a magisterial order under the following circumstances last week:—The Public Health Act, 29th and 30th of Victoria, cap. 90, provided that in the case of death resulting from an infectious disease, and when the room in which the body lay was occupied and slept in by others, it was incumbent on the friends to have the body removed to the parish mortuary within the space of 48 hours. Dr. Tripe said that he had discovered two infringements of the provision, and he asked for orders in accordance with the Act. The application was immediately granted. Dr. Tripe said it was worth mentioning that these were the first cases of the kind which had occurred in the district.

Chloral.

THE chloral controversy is not yet at an end. On Monday week a memoir was presented to the Paris Academy of Science in support of the proposition that chloral is neither anhypnotic nor anæsthetic, but in reality a powerful excitant. On Thursday, M. Leon Labbé read to the Academy of Medecine a communication which maintained, in opposition to M. Demarquay, that it is a powerful anæsthetic. The authors of these three contradictory propositions base them on the results of experiment.

Infant Mortality in France.

THE Imperial Academy of Medecine of Paris listened last week with much satisfaction, and with symptoms of unequivocal approval, to a very remarkable discourse of M. Fauvel on the question of Infant Mortality. What, he asks, are the causes of the fearful death rate amongst nurselings? The principal ones may be divided into three heads:—Want of supervision, want of care, insufficient or unhealthy food. Of these causes, the last is undoubtedly the most hurtful; but the question is, how can it be remedied by regulations? Are there not general causes which will escape every supervision and every regulation? The deductions drawn by M. Fauvel from the social con-

dition of most nurses, their poverty and their discomfort, which forbid them to afford to their unfortunate nurselings anything but an inadequate quantity of food. Female lactation is utterly deficient in France; this is the fact enunciated by M. Fauvel, and it is deficient because maternal nursing having become exceptional, hired nursing no longer supplies the demand. There is no longer any choice of nurses, and it becomes necessary to employ those who are available, whatever they may be.

Cattle Typhus in Sicily.

THE *Journal de la Société Agricole de Brabant* informs us that the ravages of typhus amongst the Sicilian herds has cost the country more than 300,000 head of cattle. The pasture land remains unproductive, and the animal strength necessary for the cultivation of crops is totally insufficient. The prices of milk and meat are very high, and in the centre of the island and at Palermo it has become altogether an article of luxury. It is sold at 1 franc 50 cents., or about 1s. 3d. per lb. In Palermo, a town of 200,000 souls, scarcely twenty bullocks a day are slaughtered, and part of that supply is for the use of the troops and hospitals.

Hospitals and Asylums in France.

A FULL report has lately been made by the inspectors-general of charitable establishments, and has been printed and distributed by order of the Minister of the Interior. The following is a *resumé* of the general facts contained in the report:—

The funds placed at the disposal of these establishments since the commencement of the present century have been very large. The gifts and legacies, which amounted to less than two millions sterling in the time of Louis Philippe, have nearly doubled since; between the years 1852 and 1868, the funds received for charitable purposes amounted to £3,260,000. The sums voted by the communes have also considerably increased, having risen from £332,305, in 1847, to £568,034, in 1864. The municipal council of Paris votes an annual subvention of £351,492; Marseilles, £23,720; Rouen, £18,880; Bordeaux, £16,800; and Nantes, £15,200. The hospitals have also benefited largely by the general increase in the value of land and house property. The annual income of the Paris hospitals, from this latter source amounts to £133,100, Lyons about half as much, and other great towns in proportion. The total amount devoted annually in Paris alone for all kinds of charitable purposes has risen from £320,000, in 1804, to £815,254, at the present time.

Previous to 1790, there were 1,224 hospitals and asylums existing in France; the number is now 1,557. These 1,557 establishments contain 141,576 beds, and receive more than half a million of persons annually, either as patients or pensioners. Paris possesses 18,785 beds; Lyons, 4,176; Nantes, 2,716; Lille, 2,188; Rouen, 2,073; and Orleans, 1,641.

The increase in the funds devoted to such institutions has been divided between the erection of new and the improvement of old hospitals and asylums. Of these, 115 have been entirely rebuilt since 1852, and all the others have either been enlarged or improved, or are being placed on a much more efficient footing than formerly.

THE friends of the late Mr. Alex. Bruce propose to erect a tablet in University College, or some equally suitable memorial to him. Subscriptions will be received by Dr. Wiltshire, of the Privy Council Office.

THE *Madras Athenæum* states that Lord Napier has appointed a Commission consisting of Dr. Ranking, Sanitary Commissioner, Dr. Smith, of the Medical College, and Native Surgeon Ayyasawmy Pillay, for the purpose of discussing the best means of utilising the provincial dispensaries as popular schools of medicine.

MR. MURRAY'S new publication, "The Academy," will unquestionably take the highest position forthwith. It contains articles by men of world-wide renown. We find it announced that Mr. Darwin will shortly publish another important volume.

MR. COLEMAN, of the Dental Hospital of London, has tried with great success the nitrous oxide in a purer form than heretofore by causing the residual atmospheric air in the lungs to be diluted previously by administering nitrogen before the oxide.

WE learn that scarlatina has appeared in the person of an officer, and in the family of another, belonging to the 2nd Regiment now stationed near Gosport, and that one or two cases of typhoid fever have occurred among the men of that corps. We trust that these are only accidental cases, but precautionary measures have been taken to guard, as far as can be done, against a further extension of either disease.

A CONGRESS of naturalists and doctors was held at Fiume, in Hungary, on the 5th September. The assembly was presided over by Baron Vecsey, who inaugurated it by a very remarkable discourse. Amongst the most interesting communications which were read were those of Dr. Bodogh on the Darwinian hypothesis, the same author on the influence of natural causes on nations, and by Dr. Domini on different climatological, meteorological, and sanitary questions in connection with the marine service.

A NEW and very easy method of acquiring and preserving talent and intelligence has been discovered. Simply to eat fish. Our authority is the celebrated Agassiz, who, in his report to the Legislative Council of Massachusetts on the preservation and propagation of fish, writes as follows:—

"It enters largely into the requirements of the human organism. It is an aliment refreshing to the system, especially after intellectual fatigue. No other nutriment provides for the outlay, so to speak, the expenses of the head, so completely as fish, and the proof of the fact may be found all over the world. The inhabitants of places close to the sea are always the most intelligent.

"Fish contain phosphorus in great quantity, a chemical element required by the brain for its healthful development. It is not to be supposed that the exclusive use of fish can make a wise man out of an idiot, but only that the brain ought not to be allowed to want its essential elements."

THE *Journal de Pharmacie* narrates as follows:—

"It will be remembered that a catastrophe occurred some time ago at Quenast, from the explosion of nitro-glycerine. The remainder of the consignment of this dangerous material was deposited in the magazine at Lauden, and it excited the greatest alarm amongst the inhabi-

tants, who petitioned the Government to relieve them of this perpetual cause of anxiety.

"The magazine at Lauden contained still 75 kilograms of it in six tin cans. Last week, M. Deplomque, Captain of Engineers, received from the War Department instructions to destroy all the nitro-glycerine which remained in Belgium.

"The authorities handed him the key of the magazine, and it is hardly necessary to say that no one came to impede him in his duty, or that he did not find it necessary to place sentinels. In fact, the whole population ran away. The six baskets containing the cans were brought to an isolated valley without vegetation. The cans were laid down at a distance from each other in the hollow of the ravine. Then six frightful explosions, succeeding each other by some minutes, shook the ground and the air, and announced that the nitro-glycerine had gone off.

"Not the least accident or the least mishap occurred, and in an hour the expedition was ended."

THE *Rivista Cmica* publishes a description of a new method for producing artificial respiration. The method has much analogy with that of matter described before the Academy of Medicine of Paris under the name of "*Succession*."

It is practised in the following manner:—Take the child under the axillæ, and holding the head fixed by the palms of the hands, impress upon the body repeated shakes. The entry and exit of the air through the glottis are indicated by a peculiar sound. The priority of discovery of this method is due to Paccini. It is based on the amplification of the thoracic cavity, produced by the elevation of the shoulders, which, by means of the clavicles, acts upon the sternum, and it acts upon the ribs.

Care must be taken that the head is neither much extended or flexed. The following is the manner of proceeding:—

The patient, being extended on a bed or table, the doctor takes his place at the head, and fixes it against the breast, then he pulls strongly with his hands on the arms of the patient, applying the four last fingers in the axillary cavity, and placing the thumb on the neck of the humerus. This being done, he gives the shoulders a forcible movement upwards and forwards.

It is necessary to make counter-extension by fixing the feet by some means or other.

THE MEDICAL CLUB.

THE members held their Annual General Meeting at the Club on Wednesday last, Sir Wm. Fergusson in the chair. The attendance was by no means so large as at the meeting last year.

Dr. J. H. Waters proposed the resolution of which he had given notice—

"That the Medical Club shall now cease to be a Proprietary Club, and that the resolution passed on the 8th of November, 1866 (limiting the liability of the members to the amount of their entrance fee and subscription), shall now be rescinded, and an allotment made, in equal shares among the members, of the necessary capital to enable the Committee at once to carry this resolution into effect."

Which was seconded by Dr. Ligertwood.

Mr. Cockayne moved, and Dr. Bushnan seconded, as an amendment—

"That it is not desirable to rescind the resolution passed on the 8th November, 1866; but that the Medical Club be conducted on the proprietary principle, the same as heretofore, in accordance with the agreement now existing between the Honorary Secretary and the Club."

The agreement between the Club and Dr. Marsh, as proprietor, having been read, a discussion ensued upon the resolution and amendment, in which Dr. Douglas, Mr. Winchester, Mr. Rayne (of Newcastle-on-Tyne), Dr. Swettenham, Dr. Prosser James, Dr. Lorrimer, Dr. Thorp, Mr. Nunneley (of Leeds), and others took part. On the one side, Dr. Prosser James and one or two more advocated the registration of the Club in accordance with the provisions of the Companies' Act, 1862; on the other, it was urged by most of the speakers that the Club could be conducted more efficiently under a proprietor than under a Board of Directors, and that the risk of personal liability would have the effect of making many leave the Club at once.

Upon the amendment being put, only two hands were held up against it, and the Chairman declared it carried and the resolution lost.

The Committee for the ensuing year was elected as follows:—

J. Brady, Esq., M.P.
W. J. Clement, Esq., M.P.
B. W. Cockayne, Esq.
Sir W. Fergusson, Bart.
Dr. Bell Fletcher.
Dr. Peter Hood.
Sir J. G. Logan, K.C.B.
Dr. J. A. Lush, M.P.
Dr. McEwen.

Sir C. R. McGrigor, Bart.
Sir Ranald Martin, C.B.
Dr. Russell Reynolds.
Dr. B. W. Richardson.
Edwin Saunders, Esq.
Dr. Swettenham.
Dr. Webster.
Dr. Wiblin.
Erasmus Wilson, Esq.

Our readers would see, from the figures which we published last week, that although the Medical Club has successfully struggled into a recognized position, yet it requires the increased and liberal support of the Profession to render it worthy of its name, and to ensure its answering those enlarged purposes held in view by the influential men directing its affairs. We are given to understand that gentlemen joining during the remaining months of the present year will be expected to pay only one subscription to the end of 1870.

LARGE FAMILIES—"PRUDENTIA" AND THE ELGIN COURIER.

AFTER the first outburst of indignation against a noble lord and some other members of a learned London Society have a little subsided, and the air is becoming still, again and silent after the storm, a few small voices are beginning to protest that perhaps after all the members of the Dialectical Society may have some small amount of truth on their side, and, if so, that they should be heard calmly, and not treated as "bad men" or "naughty," which is a style of criticism not likely to convert any now-a-days, except, indeed, children and dependents. The members of the Dialectical, *i.e.*, some of that intelligent society, assert, either truly or falsely, that human beings *tend*, just like other animals, to breed far more rapidly than they can get food. And they assert over and over again that Mr. Malthus proved to demonstration, that in America in the United States the population did between the years 1790 and 1820 very nearly double itself entirely by the procreative powers of the inhabitants, and making ample allowance for immigration into the States. This being granted (and Dr. Beatty and others have not as yet attempted to assail the position) the followers of Malthus and Mill point to the fact that the increase of population in European States is always much slower than this, Great Britain having once, and only once, doubled in about fifty years, and France now being all but stationary. The inference from these *facts*, admitted by all but the ignorant, is that as population must be checked somehow or another in old countries, it is as well for us to see that we check it in the manner which is likely to create the least suffering to mankind. Emigration is evidently quite inadequate to relieve poverty in Europe, *i.e.*, to take off the surplus that might arise, if all countries were to breed so fast as they do in the United States. Emigration has been shown by Chalmers and others to be only a remedy for existing evils, not a prevention of the disease, poverty. Late marriages were recommended by Aristotle, by Plato, and recently by Malthus, and his peculiar school of theological Malthusians, such as Whately and Chalmers. The argument against late marriages

is that it engenders prostitution and great and manifold vices among both sexes, ending frequently in insanity. Wars, plagues, and famine are, of course, the very evils we are trying to get rid of. They used to be the main check to population. Now they are fortunately but rare. Poverty is now the gigantic evil of our time, and the great check to population, producing early death, especially among the children of the poor, fevers, consumption, &c. The last check of population (without enumerating those dangerous ones said to be common in America at present, and which of course are not to be thought of) is what may be denominated the French Malthusian plan. That is the custom of having very small families, as is now almost universal in Paris, and in all parts of France, except in those where misery has so degraded the poor as to make them careless of everything. We have, we confess it, almost a mind to say that the French are not so far wrong, after all, in preferring comfort with two children and prudence, to misery with eight or ten.

Correspondence.

PHYSICIAN AND SURGEON.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—On reading an article "Physician and Surgeon" in the *British Medical Journal*, and since copied into *Public Opinion*, the writer considers that there should now be no distinction between the title of *Physician and Surgeon*! There is no denying that Surgery and Medicine are one science, yet, until all have undergone the same curriculum of study, and been subjected to the same searching examination, to test their fitness to practise medicine in all its several departments, I do not think it would be fair to designate all by the title of Doctor until that has been accomplished. In the article referred to the writer says, "In the majority of cases it does not imply either more extended education, or longer experience." I can only say that in many instances within my own knowledge, it has done so in graduates of our old universities after four years of hard study, and being subjected to three separate literary and medical examinations, before they were considered competent to practise. These degrees were obtained in a legitimate and proper way, and not as conferred upon between 300 and 400 surgeons and apothecaries by one of the northern universities a few years ago (*and in a few days*), many of whom, I had reason to know, had had some difficulty in getting their names placed on the Medical Register a short time previously; others, again, I have known, had purchased for the sum of £10, a *Licence*, from some College of Physicians (wishing to do a little business in that line); and these have styled themselves M.D. on their door plates, cards, &c.; others there are, who have done the same, after purchasing a Degree for £5 or £10 from the U.S. of America from their London agent. Now, after such anomalies, no doubt many possessing such worthless documents will contend strongly for a uniformity of titles, *all to be designated as Doctors!* The writer contends that, however slender their claims may be to the science and practice of medicine, such a state of things is only calculated to mislead and embarrass the public, to inflict injustice, afford opportunities for self-exultation, and to endanger the friendly relations of neighbours, so that we should now all stand nominally as well as really on the same footing, no matter how the qualification has been obtained. I would suggest that the different Universities should cease to be examining bodies in *Medicine*, that they should remain, as at present, seats of learning, and where the highest education can be obtained, that the Legislature should appoint twelve of the most competent medical men, of at least twenty years' standing, as a board of examiners, who shall devote their whole time and attention to its duties, and who shall be liberally remunerated by the State for such services. That they *only* shall test the qualification and fitness of all candidates for examination in the science and practice of medicine, for any part of Her Majesty's dominions (all students having previously undergone the recognised course of studies, as required at present, for their literary and medical education), that the board of examiners should sit each year in London, Edinburgh, and Dublin, for the time required to confer the same *degree, rights, and privileges* on all candidates found competent to practise medicine

and surgery, or in any of its departments they may choose to adopt, or that their taste or peculiar talents may direct, *without any invidious distinction of title*; then, and not until then, can we expect the present anomaly to be rectified.

Yours, &c.,

M.D. EDIN.

QUARANTINE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Some persons, enamoured of what *they imagine* to be "Free Trade," are opposed to all impediments on the locomotion of goods and persons from one part of the globe to the other. They would have it, that there is never any danger in permitting passengers to land in this country from any foreign shore. They look upon all ideas of quarantine as antiquated and useless. They say that, just as the passport system has been abolished here, and in several continental States, so should this barrier to rapid transit from one country to another be abolished. It is "old-fashioned," they exclaim, too old for the nineteenth century, &c. Now, I don't mean to proclaim myself an enemy to Free Trade, or to other improvements, because I avow myself an adherent of the system of quarantine to a certain extent. All this is said in knowledge of the fact, that the Privy Council last week ordered a West India Mail packet, the *Atrato*, into quarantine off the Isle of Wight, on account of yellow fever having broken out on board. Was the Privy Council right in this step it took? I believe it was. Although, doubtless, there are no certain records of an epidemic of yellow fever at Portsmouth, there have been many such epidemics at Gibraltar, and I don't see why, if the disease existed on board the *Atrato*, it might not have been introduced by means of the passengers into this country, just as cholera is introduced into Europe via Marseilles. Dr. Hearne, of Southampton, seems, however, to be opposed to the quarantine held on the *Atrato*; and states that the Royal Mail ships have now steamed into the Southampton waters for more than twenty years without any prejudice to the health of the inhabitants. Of course, it is said by many that yellow fever is not at all contagious; but the same thing is said by some as to cholera, typhoid fever, and many other zymotic diseases. In fine, I would rather see the Privy Council on the safe side, even if they should be perhaps wrong in this instance, and although I can sympathise with the passengers of the *Atrato*.

I am, &c.,

M.D.

HOSPITALISM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Permit me a few observations on Sir James Simpson's letter, as it appeared in your issue of the 6th inst., deprecating the erection of the new Edinburgh Infirmary on the large palatial plan, and advocating, instead, its construction in a series of village or villa hospitals or wards. That he fully makes out his case in favour of the superior wholesomeness of small hospitals as the rule, must be obvious to all who consider the question with fairness. Indeed, when properly stated, the proposition of Sir James Simpson becomes almost self-evident. An hospital ward is not only a sick room on a large scale, but one nearly constantly tenanted, and that with sick suffering from diseases of more than usual gravity. The difficulty of maintaining during the night a pure atmosphere in a mere sleeping room with many inmates is well known. It is no easy matter to accomplish this even in buildings specially constructed with a view to that object. But in the private sick room sometimes, and in the hospital ward always, there exist, both day and night, sources of foul and morbid exhalations that are absent from ordinary sleeping rooms, such as unclean skins, diseased lungs, suppurating surfaces, unhealthy and foetid discharges, fecal evacuations. If, then, ventilation be often not more than adequate to overcome the foulness attendant on an aggregation of mere sleepers during a portion of the twenty-four hours, how much less than adequate must it be to neutralize the foulness inseparable from such superadded sources of impurity? There are, in fact, no reliable data to prove that ventilation alone is capable of effectually counteracting the uncleanness which accompanies certain cases of sickness. All that can be said is, that the foulness generated therefrom is less in proportion to the limitation of the numbers of the sick in a given amount

of well-ventilated space. This is not only true of individual rooms and wards, but also of every building covered by one roof when used as an hospital. To this extent, then, Sir James Simpson's advocacy of hospitals on the villa scale, is based on sound reasoning as well as on ascertained facts.

But every one experienced in the management of the sick must know that there are single cases in private practice which require, for the maintenance of a pure atmosphere, ventilation to be supplemented by measures of disinfection. It would be something surprising if Sir James Simpson himself has never, in the course of his private practice, found it necessary to have recourse to disinfecting agents. And if disinfection be occasionally needed in the management of certain cases in private houses, it can safely be affirmed that it must be almost uniformly required in hospital wards, which, as we have seen, are but magnified sick rooms under many peculiarly unfavourable sanitary conditions.

Not satisfied, however, with showing that the rate of mortality among surgical patients decreases with the diminishing number of such patients under one roof, which is not only true but almost self-evident, Sir James Simpson has gone out of his way to speak disparagingly of all disinfecting measures. By so doing he has weakened rather than fortified his position. He was wrong to allow himself to be betrayed into running down disinfectants in general, by the tempting weakness of the argument used by one of his opponents, namely, that Professor Lister's carbolical "discoveries," by "altogether preventing noxious exhalations," had rendered it a matter of indifference whether hospitals were constructed in large lofty blocks, or in low detached buildings. In answer to this assertion he had only to point out that carbolie acid was no disinfectant at all in the proper meaning of the term, but only an antiseptic, and that its use in hospitals, as was to be expected, had not tended to diminish mortality.

Although the above alluded-to opponent of Sir James Simpson was most unfortunate in adducing carbolie acid as a substance calculated to secure purity of atmosphere in hospitals, it can, nevertheless, with confidence be stated that medical men in general, and hospital surgeons in particular, have too much neglected the advantages to be derived from disinfectants properly so-called, namely, those of the oxidizing class, some of which are well calculated to aid and supplement ventilation. No facts whatever can be appealed to in proof of the inefficacy, for instance, of chlorine as a disinfecting agent. Owing to its irritating and corrosive properties, it may not be so universally applicable in the gaseous form as was at one time expected, but in certain somewhat stable combinations, this substance is capable of conferring, in some surgical cases, immense benefits, which have been quite lost sight of by the medical profession. But this neglect of chlorine is no evidence that it is useless. In the same way the circumstance that nitrous acid, for the introduction of which Dr. Carmichael Smith received a parliamentary grant of £5,000, is now never used, affords no proof that this substance is of no disinfecting value. On the contrary, it is a most efficient disinfectant, and if it had been generally adopted, but kept to its proper uses, we should, perhaps, now be hearing less of "poison saturation" of hospitals. The truth is, that hospital surgeons have not paid serious attention to disinfection. They are not yet alive to what oxidizing disinfectants are capable of accomplishing. Among all the lectures delivered at the medical schools, there is not one in which the properties of disinfecting agents are experimentally treated of, and their applications taught. In what hospital has the sanitary value of even so capital a substance as ozone been practically investigated in a serious and sustained manner?

Greater familiarity with the principles and practice of disinfection would inevitably lead to the conviction that many cases of surgical disease, even when treated in good private houses, require ordinary ventilation of the sick room to be supplemented by the use of disinfectants, that the amount of disinfection demanded is in proportion to the aggregation of cases, more being required in hospitals with many patients under one roof than in smaller hospital buildings, but that, perhaps, no hospital, and certainly no surgical ward, can be long maintained in a sufficiently pure and wholesome condition, however well it may be ventilated, without the use of proper disinfecting agents.

I am, &c.,

JOHN MUTER, Ph.D.

New Kennington Institute,
October 16, 1869.

Medical News.

THE Queen has been pleased to appoint Dr. George Macleod to the chair of surgery at the University of Glasgow.

THE CAMP AT COLCHESTER.—Staff Surgeon Major J. L. Holloway is to proceed to Colchester for the purpose of assuming the medical charge of the 8th depot battalion, vice Staff Surgeon D. O'Donovan, about to be placed on half-pay.

By latest mail we learn that cholera of a virulent type is prevalent at Peshawur, and a number of European cases are reported. It is remarked that the disease appears to be spreading as it did two years ago in the direction of Cabul and Cashmere, and to gather strength as it goes.

It is reported that printers' ink can now be used in photography. One great advantage being that photographs are necessarily as permanent as a printed text, and so easy of production that 12,000 may be produced from a single plate in one day.

NOTICES TO CORRESPONDENTS.

In all cases when proofs are sent, it is of the utmost importance for them to be immediately returned.

CORRESPONDENTS not answered should look to the answers the following week.

TO SUBSCRIBERS.—Those gentlemen who have not paid their subscriptions for last year are respectfully reminded of the omission.

MR. DIXON.—The establishment of Dr. Blanc is in Bedford street, Bedford square, W.C. A letter to him at that address will elicit all you want.

DR. RYAN.—See answer to Mr. Dixon.

CONTRADICTIONS.—A correspondent referring to the articles that have appeared upon the subject in these columns says—It does not answer well on the Continent, and I am of opinion it would not work well in England; inspections at the best are but very imperfect, and I think would interfere too much with the liberty of the subject, and be of little use, as syphilis, as seen at present, is not the horrible disease it used to be when mercury was given to every patient indiscriminately.

L.R.C.S., Edin.—A registered medical practitioner can, like all medical men under the Medical Act, compound his own prescriptions; but [under the Irish Apothecaries' Act, he cannot open shop or compound the prescriptions.

R.G.—We regret we cannot advise you. The disease from which you suffer is very common, and if self-denial and care be exercised, very harmless. There is no occasion for great alarm, which is habitually nurtured by quacks for their own purposes. Take regular exercise, and cold baths, and above all, beware of such excitement as might aggravate the symptoms. Any competent medical man can cure you, if you aid him by patience and self-denial.

DR. BLAIR.—The *Journal of Practical Medicine and Surgery* was discontinued at the end of 1866.

LARGE FAMILIES.—Several correspondents have expressed or disapproved with the views propounded by "Prudentia," and hope the discussion which such a letter is likely to provoke, will not leave those vital questions open to conjecture or misrepresentation, as has too often been the case, from the ambiguity of language employed. One or two other correspondents have expressed dissent at the letter in question, but would like to see the subject impartially discussed, as it can only be in the pages of a medical journal.

J. C. advises M.D. M.R.C.P., to fix his fee at £50 or under, and sue the shabby ship-merchant in the County Court. A good plan too, we think.

HARVEIAN SOCIETY.—Mr. Gascoyne will read a lecture on "Variocela," on Thursday, 21st inst.

INQUIRER, CASTLEREA.—A female pelvis may be had of Fannin and Co., 4 Grafton street, Dublin, for about £1 5s. to £1 10s.

DR. LUTHER ON CAUSATIVE AGENCY, &c.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your impression of the 29th ult., your correspondent, in his interesting letter "On the Causative Agency of the Skin and Liver in the Induction of Phthisis," refers to a communication upon the same subject which appeared in your journal of April, 1867, from the pen of Dr. Mulvany. Being particularly interested in this subject, I have referred back to my volume of that date, but cannot find the contribution of which he speaks. If Dr. Luther would kindly favour me through your columns with the exact date, I, and doubtless others of your numerous readers, would feel extremely obliged.

Yours, &c.,
I.F.M., M.D., Lond.

October 11th, 1869.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having heard that arrangements were to be made to enable the Diploma in Dental Surgery to be procured in Ireland, I would wish to know from you, or any of your correspondents, if there is any truth in the statement.—I am, &c.,
A B.

SIR,—In reply to a query from Dr. A. H. Jacob, I have to state that there is no foundation for the report that Trinity College intends to grant licences to practise Dental Surgery.—I am, &c.,
School of Physic, Trin. Col., S. HAUGHTON, Medical Registrar.
Dublin, Oct. 18th.

BOOKS, PAMPHLETS, &c., RECEIVED.

Anatomy, Descriptive and Surgical. By Henry Gray, F.R.S. Fifth edition, with an Introduction by T. Holmes, M.A. Cantab. London: Longmans, Green and Co.

- Exercises in Practical Chemistry. By Messrs. Vernon Harcourt and H. G. Madan. London: Macmillan and Co.
- Manual of Comparative Anatomy and Physiology. By S. M. Bradley, F.R.C.S. London: Simpkin, Marshall and Co.
- Diseases of Children, with a Formulary. By Edward Ellis, M.D. London: John Churchill and Sons.

ON PAIN AT THE HEART AND IN ITS NEIGHBOURHOOD—CASES AND APHORISMS.

By HORACE DOBELL, M.D.,

Senior Physician to the Royal Hospital for Diseases of the Chest, &c.

(Continued from page 269.)

THE following are some of the principal points of practical interest in the four cases recorded in my last paper:—

1. The similarity between the symptoms produced by the organic disease and those produced by the dyspepsia.

2. The frequency with which dyspeptic symptoms are conjoined with those of organic disease.

3. The danger of mistaking the relief given by removing the dyspepsia for a cure of the organic affection—a mistake by which the practitioner may be led to release the patient from those cautions and restrictions upon which his future safety depends.

4. The great importance of diagnosing and treating the dyspepsia attendant upon heart disease, not only on account of the immense comfort which can thus be secured for the patient, but also because by this means an important addition to the difficulties with which the heart is encumbered may be removed, and the patient's life thereby rendered much safer.

5. Case 8 is a striking example of the great caution required in giving a prognosis in these cases until they have been carefully watched.

6. The extension of painful sensations to the *right arm* in severe cases—a point to which I shall have to refer again.

7. A most important and interesting point, exemplified especially by Cases 7, 8, and 10, is the rapidity with which rest from exercise relieves the pain, and the facility with which the heart accommodates itself to its defects if permitted. We cannot be too much alive to this in treating these cases, for by taking judicious advantage of it in our

directions as to the habits and pursuits of patients, and explaining the *rationale* of it to them, a permanent accommodation of the heart to its difficulties may be gradually established in many cases which would otherwise soon become fatal.

8. The point, however, to which I wish especially to direct attention is the distinctive diagnosis between *pain at the heart* and *in the left arm* due only to dyspepsia, and the same symptoms due to organic and incurable disease. It amounts to this—that whereas the first is soon cured by appropriate remedies for the dyspepsia, the second remains after such means have been adopted, and after all dyspeptic symptoms have disappeared. But beyond this, the diagnosis may often be made without waiting for the effects of treatment, though it needs great circumspection. The first point to make clear is, whether the pain at the heart, &c., comes on after food or after exercise; but here it is necessary to distinguish between exercise taken after food and exercise taken when the stomach is free from food. If the pain is only excited by exercise taken with a full stomach, it may still be due to dyspepsia only; but

Aphorism 3.—If pain is excited by exercise taken when the stomach is not distended with food or gas, and especially if it comes on quickly and increases steadily in severity with the continuance of exercise, it is almost certain that there is some serious disease of the circulatory organs.

A perfectly healthy heart, fully nourished by healthy blood, ought to be able to bear an ordinary amount of stomach distension, either with food or gas, without sufficient embarrassment to lead to any serious inconvenience, even with the addition of moderate exercise. Therefore,

Aphorism 4.—When it is found that flatulence or a full meal embarrasses the heart painfully, a careful investigation should be made into the condition both of the organ itself, and of the blood.

The following case shows the importance of such precautions, and of not too readily deciding that the organ is healthy because the painful symptoms are relieved by removal of the dyspepsia.

CASE 11.—R. P., fifty-five, a fine, tall, well-built man, consulted me Dec. 1862, when I made the following note—palpitation very easily set up by hurry or excitement,

and always after breakfast if he moves. The palpitation is accompanied by severe aching pains in the arms and scapulae, and sometimes there is a little swimminess. These symptoms are of about four months' duration. For the last twelve months has been much confined to a counting house lighted with gas, for five years before this had lived in London but took much out-of-door exercise. Anterior to that he lived in the country, hunting and shooting much, living generously, and enjoying very fine health.

Paternal grandfather very gouty. Father slightly gouty. Eldest brother gouty. Urine very acid, loaded with urates. Bowels irregular. Pulse fair average. Heart sounds sharp and loud, otherwise normal, cardiac dulness normal. Ordered diet, regimen, and medicines for gouty dyspepsia, and in two weeks he was relieved from all uncomfortable symptoms. Ordered a continuance of the same plan of treatment, and cautioned him as to the management of his thin walled heart. I heard no more of this patient till January, 1868, when I was summoned into Essex to see him in consultation with his family doctor, and found him sinking. He was breathless, pulse extremely quick, very feeble, irregular, intermitting, spitting a considerable quantity of blood. Heart's action fluttering, irregular, no bruit, cardiac dulness normal. Liver four inches below the ribs, round, smooth, and blunt. Legs and thighs oedematous, no ascites. Urine scanty, loaded with urates, acid, no albumen. Intellect quite clear. I learnt that after I saw him in 1862 he had lost his dyspeptic symptoms, and very much improved in health, but always suffered from palpitation on exertion, and had easily got chilled in cold weather. In the frost of 1866 he had been "paralyzed with cold," and nearly died from walking home one night in the frost. But the immediate cause of his present condition was prolonged and excessive overtax of his weak heart, by ill-advised over-exertion. He had undertaken a walking tour in the Isle of Wight with much younger and stronger men, felt getting more and more ill every day, but was persuaded it was due to dyspepsia, and that more walking exercise was the remedy. Thus persuaded, he foolishly pushed on until he came to a dead stand, and was brought to his home with difficulty in an invalid carriage four days before I was sent for. He only lived nine days. His doctor wrote me that after I left him the hæmoptysis and anasarca increased, and the other symptoms got worse. On the evening of the night on which he died, the doctor found him sitting up in bed, having been seized with intense pain about the base of the heart, face livid, panting much for breath, intellect clear. This state continued up to his death, which was sudden at last.

(To be continued.)

Hospital Reports.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.

In a recent visit to this hospital we observed the following cases:—

CASE 1.—October 15th. An elderly woman was operated on by Mr. Bowman for double cataract. Both lenses were extracted by the method which now seems to be in universal use at the hospital, namely, by means of a small linear incision, made by a narrow-bladed knife, of the upper part of the juncture of the cornea and sclerotic, followed by excision of part of the iris. Mr. Critchett informed us that this operation is very much more successful than the old flap operation by Beer's knife, and that whereas one-fifth of the cases of operation used to go wrong, now only one out of sixteen or so turn out ill. The above case of double extraction was successfully accomplished by Mr. Bowman, the eyelids being kept open by means of a small instrument invented by a German, whose name escapes

our memory. After extracting the cataract from the left eye, a slight amount of blood was seen in the anterior chamber, arising, Mr. Bowman observed, from the vessels of the cut iris. This blood he removed as well as he could by means of slight pressure of the probe; but it would not be of much consequence after all, he continued.

CASE 2.—The next case of operation was performed by Mr. Critchett. The patient was a young girl, aged about twenty, the subject, it was supposed, of hereditary syphilitic taint, which had caused in her interstitial keratitis of both eyes, followed by adhesions of the iris, and total want of vision in both eyes. Mr. Critchett performed excision of a piece of iris in the left eye, by means of an incision effected by a lancet-shaped knife, with which the cornea was incised about its junction with the sclerotic. A piece of the iris was then drawn out of the wound and cut off.

CASE 3.—An elderly woman, who had been operated on by Mr. Critchett for double lenticular cataract some months previously, returned with capsular cataract of one eye, the left. The opaque capsule was seen distinctly behind the cornea. Mr. Critchett introduced two needles, one with the right the other with the left hand, through the opposite side of the cornea. Fixing the capsule by means of one of these needles, he entered the point of the other needle at the same point; and then, moving it upwards, he tore through the opaque capsule, leaving a wide opening, through which light could attain to the retina. Mr. Critchett observed that in many cases operators fail to accomplish this desired end by using only one needle, because the capsule follows the one needle and does not become torn sufficiently, unless the other needle be used in order to fix one point in the membrane.

CASE 4.—A remarkable case of "Grave's disease" is now attending at the desk of Mr. Couper. The eyeballs project greatly, there is violent impulse of the heart, and slight swelling in the region of the thyroid gland. The patient is a woman of about thirty-five years of age. The treatment by Mr. Couper has been by means of the tincture of belladonna, which seems to have relieved some of the worst and most painful symptoms. It is proposed, also, by that gentleman, to attempt to ameliorate the general appearance of the patient's countenance by using a slight operation to narrow the aperture between the lids, by making them adhere at the outer canthus.

CASE 5.—A child, aged six years, a girl, came with great staphyloma of the left eye, the consequence of purulent congenital ophthalmia. Mr. Critchett proposes to excise the cornea by a method peculiar to himself, *i.e.*, firstly inserting needles through the sclerotic from side to side, and then excising the cornea.

SPECIAL REPORT

ON STUDENTS' TEXT BOOKS.

(Prepared expressly for the MEDICAL PRESS AND CIRCULAR,
by Professors in Schools of Medicine.)

No. IV.

OUR last remarks were directed to the subject of Systematic Surgery. We have now a work on Operative Surgery, to which we would direct attention. It is the 2nd edition of a neat and illustrated "Manual of the Operations of Surgery," by Dr. Joseph Bell, of the Edinburgh Royal Infirmary; published by Messrs. MacLachlan and Stewart, and in London by Mr. Hardwicke. The four plates that precede the letterpress particularly please us, showing as they do, in the clearest possible way, the

lines of the incisions to be made in all the most usual cases. Dr. Bell makes some apology for the "baldness and brevity of the style," but none is really required. A condensed work like this is far more useful than one three times as large. Of course, the first use of the book is as a guide to operations on the dead body. It may, we suppose, be looked upon as the author's syllabus in teaching his class of operative surgery. But it has another use or two. It will help those preparing for examinations to keep the details of operations fresh in their memory, and it will also serve the surgeon in districts, away from the aid of professional brethren, to refresh his memory before undertaking an operation. That Mr. Syme's assistant should lean to the Edinburgh School is not surprising; but his manual will be none the less useful to students in other schools.

At a later period of his student-life, when his first examination at the College has been passed, works on the practice of Medicine naturally occupy much of the student's attention. We do not mean to say for a moment that all reference to practical works on Medicine should be deferred till after the close of anatomical studies. Such a course, however much to be desired, is at present impracticable; and attending hospital practice during his first and second year, the student must have books from which to obtain that supplementary information so essential to his profitable work in the wards. In Medicine we know no better books for the junior student than Dale's "Compendium;" "The Art of Case-taking," by Dr. Warter; Tanner's "Clinical Medicine;" and Hooper's "Physician's Vade Mecum." With the two former books for reference in the wards, and the last mentioned to solve other difficulties when the day's work is over, the junior student will find himself well supplied.

Among the more useful, if the least known, of manuals of medicine is the "Compendium of Practical Medicine," by W. Dale, M.D. Lond. (published by Churchills). It is a small 8vo volume, containing the result of many years' experience, gives an excellent epitome of diseases, and, above all, is based upon morbid anatomy. This volume appears to have been printed at Plymouth, no doubt as a matter of convenience to the author. This accounts for its want of that appearance which in London goes so far. We can, however, promise the purchaser that he will find it full of solid information condensed into a small compass. We should be glad if this publicity were to cause it to be rapidly sold, so that the author might have the opportunity of bringing out a new edition, in which case we would advise him to give his best attention to the revision, and make some arrangement with his publisher by which it might at once take the place it deserves as a text book of practical medicine based on pathology.

In the latter part of his curriculum, when the student is really seeking to obtain a closer acquaintance with disease, when he is practising himself for the struggle he must soon engage in as a surgeon, the books we have mentioned above will no longer suffice; stronger food must be found to develop the thews and muscles of the mind. At this time the student should read Watson's "Lectures," and have them by him as a refreshing book when the less brilliant style of Tanner's "Practice of Medicine" and Aitken's "Science and Practice of Medicine" have wearied him. When a new edition of Watson has brought the work abreast of the present state of knowledge, it will

again, as in the past, be the most popular of all books; but till then it must not be alone relied on. Of the other books, the best and most comprehensive is Aitken; but to many the vast collection of opinions to be found in its pages makes it wearisome reading. To such, Aitken must be left for reference, or its use deferred till the time of actual practice, and Tanner's "Practice of Medicine" will be found the best text-book. Barlow's "Manual" is a good one, but it has never been popular. The pathology is excellent, and the treatment good; but it would be better if re-edited, and brought more into sympathy with existing opinions. In addition to the books already named the student will find Dr. Hughes Bennett's "Clinical Medicine" invaluable. There is no book he will find a more trusty and instructive companion. Finally, it may be mentioned, that students preparing for the higher class examinations will find a careful study of the last edition of the "Encyclopædic Aitken" indispensable.

MIDWIFERY AND DISEASES OF WOMEN.—It appears natural that we should commence our advice to students respecting the works on Midwifery they should study by a brief notice of Dr. Fleetwood Churchill's excellent, well-known, and highly appreciated Manual on the "Theory and Practice of Midwifery," published by Messrs. Fannin & Co., for of modern works, undoubtedly, this book is the most popular and most frequently trusted in. The information and advice contained in the work are thoroughly sound and practical; and we trust the great obstetrician, who, for many years, has himself minutely superintended each succeeding edition of this Manual, will be long spared to witness the fruits of his teaching in the increasing importance with which obstetrics, not in the Profession only, but with the public, are daily being regarded.

The same author's Manual on "Diseases of Women" is a companion volume to his Midwifery, and has reached a fifth edition. It would be almost impossible to exaggerate the value of Dr. Churchill's work; whether we regard it as an exposition of the principles of gynecology, or as a most faithful guide in the treatment of female maladies, it is alike invaluable, and to the student and practitioner it is easy of access in consequence of its very moderate price. Notwithstanding the large number of works on this subject that have been produced since Dr. Churchill's book was first brought out, it still continues in this country, in Ireland, and America, to be by far the greatest favourite.

To those students who desire simply to obtain knowledge enough of the theory and practice of Midwifery to enable them to pass an examination, Dr. Tyler Smith's excellent "Manual on Obstetrics" (London: John Churchill), or the manual of Dr. F. Churchill already mentioned, is amply sufficient; in fact, we have known more than one successful candidate at the M.B. Lond. examination, who assured us that they read no other work when preparing for that severe midwifery examination. We earnestly advise, however, every student who has the industry, thoroughly to master the several articles in the "Cyclopedia of Anatomy and Physiology" bearing upon the ovum, the pelvis, and especially that by Dr. Arthur Farre on the uterus and its appendages, which will be found in the supplementary volume; having done this thoroughly, he should next slowly digest that splendid work Cazeux's "Midwifery," (the edition in English is published in America). Having completed these

studies in the manner indicated, no man need ever feel fear of presenting himself for *any* examination in the theory of midwifery. The practice *can* only be learned by the patient attendance upon a large number of women actually in labour; the *number* of cases attendance upon which is demanded by the examining bodies, is ridiculously small, and wholly insufficient to give the best read man in Midwifery any adequate notion of its exigencies, its anxieties, or its perils, and wholly insufficient to beget in any man that self-fortitude and reliance, without the possession of which no man can ever be a successful or accomplished accoucheur.

Every student is now examined not only in Midwifery, but also in Diseases of Women. For an examination, the late Dr. Rigby's very valuable and concise little work on "The Constitutional Treatment of Female Diseases" is both appropriate and sufficient; but no practitioner can feel himself at home in the diagnosis, pathology, and therapeutics of this very important class of cases, without becoming intimately acquainted with the contents of that truly wonderful work, Scanzoni's "Diseases of Females," which has been translated by Dr. Gardner, of New York, and published in that city, and may be had through Messrs. Trübner, of London.

A host of other works on these subjects could be named. Many of them are simple compilations, others are far behind (in our judgment) both in Pathology and Therapeutics the advance which has been made in every branch of obstetric knowledge.

(To be continued.)

A MEDICAL TRIP TO PARIS.

(Concluded.)

IN a visit to the Lourcine, female venereal hospital, of 300 beds, I found a distinguished gentleman with whom I have had an acquaintance of several years' standing, Dr. A. Fournier, acting as physician, and also M. Dépres, as surgeon, to the hospital. M. Dépres is a strong anti-mercurialist; and will, I am glad to say, have nothing to do with mercurial courses in any shape or form. He treats the early stage of syphilis entirely by topical applications, such as a saturated solution of chloride of zinc to mucous tubercles, and, for the rest, waits and treats symptoms, such as iritis, by belladonna lotions, &c. M. Dolbeau, his predecessor in the same position, did the same; only *he* gave, as an internal remedy, chromate of potash for secondary eruptions, and iodide of potassium for tertiary syphilis. Of course, M. Dépres, like myself, and others, who have abandoned mercury, is bitter against the evils caused by the drug. He accuses it of causing the patient to become pale, and thus lowering the power of casting off the disease by the skin. Alas! how difficult it is to prove any point in therapeutics of such complication as this! As I always like my antagonists to be heard, although they don't like the contrary, I shall quote from a lecture I heard from A. Fournier, a few days after his views, as to the exhibition of that metal. M. Fournier began by observing that "Of late a revolution had sprung up against the administration of mercury in syphilis; but, thanks to experience, mercury would survive. According to what has lately been said (he continued) syphilis is a very simple disease in most cases, and will get well of itself. Mercury, too, is injurious. But let us open a work on pathology, and we find periostitis, alopecia, iritis, loss of vision, sarcocele, necrosis, and disease of the nerves causing death, all consequent on syphilis. Is this the disease you call benignant? You ask me to await the coming on of such symptoms. But the patient demands a remedy against such a terrible fate. But you say, Ah! if the disease were always so severe, perhaps, but there are numerous cases of mild syphilis, which require no treatment. Yes, perhaps; but how are you to recognize them? I know of no method of doing so. There is no provisional diagnosis of syphilis. The necessity of treatment, then, being agreed on, can mercury do any harm?"

"Now, there is no remedy so detested by the outside world as mercury. The patient says, 'Doctor, do you order me mercury?—then adieu to my teeth, adieu to my hair! How will you take the mercury out of my body?' The barbarous treatment of the 16th century has caused this terror. And, indeed, mercury may produce, if not carefully administered, stomatitis, dyspepsia, and disturbance of nutrition; stomatitis, however, may be avoided by suspending the drug. Our patients here at the Lourcine never have stomatitis. In some cases mercury is ill-tolerated. It gives dyspepsia and diarrhoea. We can prevent this by varying the dose. Mercury *may* disturb nutrition; but this, too, we can obviate; 19 out of 20 patients thrive under the drug, get fat. If it is too long given, it is hurtful: profit, then, by its good qualities and be careful. But is mercury advantageous? Some say that mercury can cure syphilis, others that it does nothing. Mercury does act on the symptoms, and will in 15 weeks, or less, remove roseola. In some cases of obstinate syphilides mercury removes them at once. Mercury, then, acts on the symptoms, and hence it must act on the disease. When syphilis is treated by mercury, we only see serious cases in about 5 per cent.; when not treated, multiple lesions are seen followed by caries and other tertiary lesions. The results of expectation are disastrous, and I say that a physician who has remarked this is inexcusable if he does not give mercury. Mercury allows of relapses. We only make the disease milder; but the worst accidents read of in books occur among patients not treated by mercury. In most cases mercury acts well; but in some it fails. So does quinine, so does opium sometimes. If we had an excess of remedies we might get another for syphilis; but where are they? I do not like friction; it is a dirty way of giving mercury, and may cause stomatitis; it should only be used exceptionally. The horrible taste of corrosive sublimate is against it, and it causes dyspepsia frequently. The protoiodide of mercury is the best, and in 8 cases out of 10 is well borne. Subcutaneous injection is difficult, and not free from danger, and painful. How long should patients take mercury? Some say 100 spoonfuls of Van Swieten's liquid. M. Ricord says, six months with protoiodide of mercury, followed by three months with iodide of potassium. These prescriptions are not sufficient. Mercury ought to be given far longer. Time does more than the dose; given continuously it loses its efficacy. Therefore you must interrupt your courses, and I propose the method of successive treatment. In a case of roseola, give mercury two months. Then stop. Again in two months time recommence, whether there are symptoms or not. Two years of treatment are required, of which ten months' treatment by mercury and fourteen months of repose. In chronic disease, chronic treatment. Gout is not cured by one season at Vichy. If mercury is the treatment for the diathesis, iodide of potassium is the treatment for the tertiary symptoms. Specific treatment must be aided by good habits. Syphilis is a far graver disease in women than in men. Tonics and hydropathic remedies are often most useful. After all this treatment, what are you to say to your patients? You must tell them that you cannot say that in 10, 20, 30 years they may not have tertiary symptoms. Tell them this, that they may inform their attendant in after years, if any anomalous symptoms arise, that they once had this disease. It may be the saving of their lives that he should know this."

Such is the lecture on the mercurial treatment of syphilis by Dr. Alfred Fournier, the most distinguished of M. Ricord's school. If M. Fournier would only have looked at the admirable statistics of treatment of syphilis contained in Professor Boeck's "Recherches sur la Syphilis," I cannot help thinking that he would never have uttered this address. What! after all the deplorable results seen after the treatment by calomel, inunction, protoiodide and perchloride of mercury there recorded, is it possible to assert that a two years' course of this terrible drug will prevent tertiary accidents? Why, I believe that, instead of preventing the occurrence of tertiary symptoms, M. Fournier's treatment is probably one of the most certain means he could adopt for causing cases of syphilis, which would otherwise prove but slight affairs, to destroy the constitution for life.

Before proceeding further in this letter, Mr. Editor, I may mention that being anxious to see M. Lancereaux, I called at the Hôtel Dieu, but found that he was not there; but that he was competing for a place as "medecin des hôpitaux" before a jury of his brethren. Happy country, I thought, where open competition exists like this, instead of back-stairs influence, or currying favour with the physicians to the Queen

or the treasurer to some hospital, or rushing round a crowd of governors with testimonials obtained by genteel begging, or flattery. At any rate, in Paris the candidate must know something of his profession, even if he may not have attained to the noble art of pleasing persons in high places. To do which latter thing, of course, he must usually sacrifice most of his independence of speech, if not of thought. Shall we, Mr. Editor, ever attain to the dignity of the *concoeurs*?

You know that we are in great excitement about introducing the foreign system of police inspection of prostitutes, and that many of our most distinguished medical brethren are profoundly convinced of the absolute necessity of extending the provisions of the Contagious Diseases Act to the civil population. Now, I am much interested in seeing that plague of modern days (syphilis) abated in its ravages, and were this plan of our *confrères* likely to accomplish this end, I would support it; but is it likely to do so? Let us see. I told you that I had visited frequently the two Parisian hospitals, the Lourcine and the Midi, each of which was full, and each of which contains 300 beds, and that 100 out-patients daily come to the Midi for advice. But I found at the Hôpital Saint Louis, that an immense proportion, both of the in- and out-patients were venereal cases. At the other hospitals also I found the same thing. So that I asked myself, Is it true that the Parisian system, so much talked about, has really the effect in large towns of lessening the spread of venereal contagion? and, Sir, I had no hesitation in replying in the negative to this question. Well, then, if it does not lessen venereal contagion, has it no evils of itself? It has, Sir. The women of the Dispensaire may be compared to white slaves. They have no liberty, but are as completely under the espionage of the police as a galley slave is. The Habeas Corpus Act, of which we justly boast, can have no meaning for these women. They can be shut up in a gloomy prison, St. Lazaire, which I have visited in company with my friend, Mr. Dunn, at any moment, for any length of time the physician pleases. I would not like to be that physician. If you call that equality of rights, what is inequality? What is aristocracy? I visited M. Lefort, a distinguished young surgeon, formerly of the Hôpital du Midi, who, you may be aware, has paid much attention to the subject of prostitution. He found, as others have lately found, by interrogating the patients of the Midi, that most of them had contracted their contagions, not from their unfortunate prison-women at all; but from a class which manages to escape from the lynx-eyed police of Paris, and who are technically denominated "insoumises," and he calculated, I think I remember, that, instead of about 4,000 or 5,000 prostitutes in Paris, there ought to be under police regulations nearer 30,000. I accordingly asked M. Lefort, if this was the idea he still entertained, or whether he did not see that the fact was, that the Parisian system was a bad one, and required remodelling. He replied, that he thought that what was wanting was, that the 30,000 women should be brought under police inspection. I urged against him a fact mentioned in a most enlightened and able article on this subject in the "Westminster Review," for July last, that it had been found of late that the number of known prostitutes, and especially of brothels, had actually diminished in Paris, although the city had enormously increased in dimensions, showing, as I said, that the system had broken down from the dislike of the citizens to such a premeditated system. To this he objected, that it was simply on the score of expense that these brothels had been discontinued, and added, that he was about soon to report on the subject to the Académie de Médecine, asking me, at the same time, to send him over anything we had lately been doing on this question. I paid a visit also to M. Lecour, of the Bureau des Mœurs, but did not find him in Paris.

My own idea is that the Parisian system will always fail in large cities, however it may succeed in small towns such as Christiania, where, according to our illustrious *confrère*, Mr. Jonathan Hutchinson, it appears that justice is sometimes even-handed, for a wonder, and shuts up the male contagion-spreaders, as well as the poor prostitute, until cured. Were this law proposed in London, I don't think the extension of the Contagious Diseases Act would be so popular as it now is, at any rate amongst our younger *confrères*,—do you? What is wanted here is venereal wards in our hospitals, maintained not by silly governors, but by municipal rates, enforced by government authority. [I was, Sir, distressed and disgusted but the other day, to find that one of the only wards in our big City for prostitutes, that in the Royal Free Hospital, was

shut up, ostensibly for want of funds. This was, in fact, the only result obtained, by the article fired off by the *British Medical Journal*, against what was in respect of hygiene certainly one of the most useful of the London medical charities.] I believe, Sir, that this measure, conjoined with the spread of toleration of opinions, and open discussion of different social topics, such as the contracts between the sexes, is the right direction to take in order to lessen the spread of venereal contagion, not the introduction of the Continental system, which, I feel convinced, will have to be modified ere long, to suit the growing ideas of sex equality and liberty. I see that Mr. Mill's excellent essays on "Liberty" and on the "Subjection of Women" have both been translated into French, and I hear that they have been greatly read by the intelligent portion of the Parisians, and I much mistake if these works do not tend to convince our clever neighbours of the mistake they have made in rendering compulsory what they should only have done by the Christian spirit of true devotion to the cause of human health and happiness.

Many of the Parisian medical men are much opposed to the system. It has been opposed also by M. Auzias Turenne at the Congrès in 1867; and I believe that it is a well-known fact, that the wholesale examinations, which I have witnessed in company with Mr. Robert Dunn, at the police office in the Rue de Jerusalem, not very unfrequently, may be the cause of spreading syphilis, by means of the instruments used. It is well known that catheterism of the Eustachian tube even has spread the disease; and it is, I believe, almost impossible to avoid the occasional contamination of female specula, where frequently used for a hundred or more prostitutes in the course of one morning's examination.

In a lecture at the Hunterian Society delivered by Mr. Hutchinson, a gentleman whom I consider as at the very top of scientific observers in this country, he told us that medical men had no business with politics. Hence, I suppose I have no right to say that I was disgusted to find that one of the students of the Hôpital du Midi had been locked up in a prison called Mazas for six weeks, for asserting his ideas that the Emperor of the French was not acting according to the laws of France. I saw him just on his exit after being, forsooth, *pardoned* by the same Emperor on the 15th August. He did not, it is true, seem at all obliged to the august head of the State; and, as Virchow has set us the example of speaking out, Mr. Editor, I confess, I must say I hope sincerely, that the empire may ere long come to an end, since it seems to me that laws are made to be obeyed by all, and not only by subjects.

I remain, dear Sir, yours faithfully,

CHARLES A. DRYSDALE, M.D.,
(M.R.C.P., L. & F.R.C.S.E.)

LETTERS ON LIFE ASSURANCE.

No. 2.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In my letter No. 1, which appeared in your issue of Oct. 13, I ventured to submit to your readers a few words of advice relative to the selection of an office for the assurance of lives; and, in doing so, I confined myself to the single element of *safety*. As, however, by means of premiums disproportioned to bonuses, or *vice versa*, such safety, like everything else, may be bought at too high a price, it yet remains to be considered, where security may be met with in connection with the greatest possible corresponding advantages of other kinds.

In appointing myself as a guide to the obtainment of these combined *desiderata*, which have formed the subject of so much contention, my apology must be found in the fact, that what follows is an exposition simply of my own views, as deduced from those expressed by leading authorities.

In pursuing our search, the first point to be decided is, which class of office is best to assure in. I leave the Proprietary Companies out of the question. Shall it be a Mutual Society or a Mixed Company? Here it would be

well to note, that by a Mutual Society is meant one in which the members assure each other. In such offices the safety is provided for by means of a fund reserved from the premiums; whereas, the Mixed Company is one in which the safety is provided partly by a fund reserved from the premiums, but mainly by means of a subscribed capital. Before proceeding further, however, I should state, that, as firstly, some considerable time must elapse before an adequate number of members could be enrolled to secure the operation of the law of average; that, as secondly, the primary death-claims might prove to be those of large amounts, rather than those of small sums; and that, as thirdly, the expenses incident to the establishment of such a business are of necessity heavy,—it would, therefore, be imprudent, if not impossible, to start a Mutual Office without some sort of principal sum answering to the subscribed capital of the Mixed Company. In actual practice this is often raised by way of loan repayable by instalments in a stated number of years. If, indeed, it were necessary to prove the desirability of capital in the early stage of all offices of whatever class, it would be easy to instance a society established within the first twenty years of this century, when competition was far less rife than it is now, whose sole means for a time consisted of something less than £40. We have it on record that the greatest uneasiness prevailed amongst its members, the manager himself expressing the gravest doubts of its continuance for the first year or two of its existence; and well he might, seeing that, had a single claim of £100 fallen in while the society was in the state just described, there would not have been sufficient in the coffers to meet it with. That the society in question outlived the difficulties with which it was surrounded, was, as we say, "more by good luck than good management," though, no doubt in a great measure its success was, attributable to the latter cause.

Respecting the theoretical correctness and practical advantages of these two classes of offices, there has been, and still is, much diversity of opinion. Some object, that, in the case of the Mutual Offices, the early members are made to suffer, either in heavy premiums or in small bonuses, in order to repay with interest the loan, the benefit of which is reaped by others. A second class of persons, taking the opposite view of the question, complain of the Mixed principle, on the score that whatever is paid to the shareholders for the use of their capital over and above the interest realized by investing it, is so much out of the assurers' pockets; while the risk to which their money is exposed, provided that the business be conducted ably and economically, is more nominal than real: that, indeed, the only value of capital is at the start, as above alluded to in connection with the Mutual Offices; and that the share of the profits, which is over and above interest paid to the shareholders, would in many instances, if reserved and invested at compound interest, for, say, thirty or forty years, amount to more than the capital itself. Is it not evident, such persons ask, that a Mutual Office can, in the same space of time, accumulate for themselves a capital which will not, as in the case of the Mixed Offices, act every year as a continuous drain upon its coffers?

Though I, for my own part, am disposed to favour the Mutual principle, I cannot altogether agree with the latter portion of the objection raised against the Mixed plan; for the loan fund needed for the Mutual Office at the start could hardly be procured, except at a higher rate of interest than that which its re-investment would secure. Though, therefore, it be allowed in the shape of extra interest, we have something here answering to the "participation of profits" awarded to shareholders in the case of Mixed Offices. For this reason, a Mutual Society could not well accumulate a

principal sum for themselves equal to the capital of their competitors, or, in other words, pay off their loan with interest in the time that the dividends paid to the shareholders of the latter would take to exceed that capital.

That the Mutual Offices are the most perfect in principle, there is, I think, little room to doubt. That, in their maturity at all events, other things being equal, they are to be preferred, I, for my own part, am fully satisfied. That, in the commencement, the early members are in many instances made unduly to contribute for the safety and benefit of those that come after them, I, for one, shall not attempt to deny. It occurs to me, however, that this inequality might, in a great measure, be done away with, by devoting the profits arising out of the "term" and "non-participating" policies to the repayment of the loan fund. But, should the fund from these sources not be deemed sufficient for the purpose, supposing the loan to have been arranged for a longer term than is usually the case, it is easy to see that the contributions to its repayment might be more equally shared. The point, to my mind, lies just here. In a Mutual Office, the guarantee fund may be, in some shape and to some extent, a drag on the early members; in the Mixed Office, the capital is a certain and perpetual drag on all the members, from generation to generation.

To conclude: there are, however, a number of Mixed Companies which I should infinitely prefer to assure in to many of the Mutual Societies; for, be it always remembered, there are several other points connected with the subject of far greater importance than that of class of office merely.

I am, &c.,

F. A. C. HARE.

Literature.

THE MEDICINE OF TO-DAY.*

WHATEVER comes from Sir William Jenner is always worth reading, and at least demands respectful attention. We have been not a little pleased with the two addresses delivered, one before the British Medical Association, and the other before the Epidemiological Society, which Sir Wm. Jenner has given the world in a pamphlet form. They are characterized, as all Sir William's writings are, by deep thought. In the first of these he discusses the scepticism so many now-a-days, we regret to say, express respecting the remedial power of drugs, pointing out that the causes of this scepticism are, 1st, that practitioners have found many acute diseases terminate without a drug in the perfect restoration of health; 2ndly, that many diseases have a definite duration to pass through before they are worn out; and, 3rdly, that disbelief in what our forefathers taught was the action of a certain medicine, is not disbelief in the action of that medicine. Sir W. Jenner protests rightly against those who are constantly asserting that the art of medicine is at a standstill. He points to our advancing knowledge of the various minute changes the tissues undergo, the changes structures experience when removed from the body (*passive changes* as he calls them), in contradistinction to those changes that take place in the living organism as a result of old age, or in the young of disease. Nor are these facts of *minor* importance; as Sir William points out, they are facts that play no little part in the successful treatment of disease. Then, again, he refers to the advantage in diagnosis of thermometric examination, how latent typhoid fever may be at once detected, when perhaps there are no other symptoms to guide us, and when in our treatment it is all important that we should discover it, and how acute tubercular deposit may with comparative ease be discovered by the aid of the thermometer, when without it it was almost impossible.

Again, we are referred to our growing appreciation of the mechanical consequences resulting from disease. As, for example, our recent knowledge of embolism and its causes. He points out the progress made in our acquaintance with blood poisons—their effects and consequence, and to the revelations of the microscope, and the vast field microscopic investigation offers. More than this, Sir William shows that we not only dis-

* The Practical Medicine of To-day, by Sir W. Jenner, Bart., M.D. London: H. K. Lewis, Gower street.

cover disease more readily, but the treatment has also become more sure and more certain. We wish we could agree with him in the remaining part of his able address. But his views on the water question are diametrically opposed to the views we have always advocated, and shall continue to advocate, unless we have some more certain experiments and proofs presented to us than any we have seen or heard of as yet. He refers to the water as the one cause of the cholera outbreak in the East of London—a view we must repeat again and again is perfectly untenable and unsupported by a single fact. We do not say that water will not produce cholera,—we know it will; but to assert that the outbreak in question was the result of impure water, is, we feel sure, to be unacquainted with the whole circumstances of the case. The Registrar-General may succeed by this means, aided by one who is no chemist, and to whose *elaborate researches* (?) Sir W. Jenner refers, in fanning the fire of sensationalism, but we are convinced that before long this miserable attempt will only disgust those who ask for facts, and not merely for the far-fetched sensational ideas of one or two individuals. We are, for ourselves, astonished that one so strongly gifted as Sir William Jenner should have been led astray by views as unsound as they are positively ridiculous.

The second address, delivered at the opening meeting of the Epidemiological Society, is occupied with pointing out the means of preventing certain diseases, and diminishing the mortality of others. The accomplishment of this Sir William thinks may be effected in three ways: 1st, by the spread of the knowledge of sanitary laws; 2ndly, by the force of special legal enactment; 3rdly, by the philanthropic efforts of the wealthy. Both addresses are most carefully written and well worth attentive study.

Dr. Angus Smith gives us the result of his great experience in "Disinfectants and Disinfection." He deals with the various substances recommended, and shows their several advantages and disadvantages. For domestic use, Dr. Smith seems to prefer carbolic acid to most others.

The "Philosophy of Food," by W. Willmott, is the title of a lecture delivered before the Association of Chemists' Assistants. It is carefully written, contains a large number of facts, which, however, are not very systematically arranged.

Mr. Gamgee presents us with one more proposal for the preservation of fresh meat ("On Fresh Meat Preservation, by John Gamgee"). We trust it may be successful. It seems to be the result of most careful and numerous experiments. The process Mr. Gamgee proposes is not altogether a new one, but a new modification of an old one.

MAUNSELL'S DUBLIN PRACTICE OF MIDWIFERY.

It is now thirty-five years since this was issued from the press, having always held its place as a sound practical work, and offering to the obstetric student a faithful guide in the difficulties which beset his path.

In the new edition, 1869, are supplied the improvements that have taken place in this important branch of medicine.

In the signs and symptoms of pregnancy, allusion is made to Jacquemier's test.

A good description is given of the nature and properties of the scale cornutum or ergot; and the best mode of preserving it. Dr. Maunsell gives admirable advice as to its administration, and regarding the effects of this drug on the life of the fœtus. He says:—"As a general rule it should not be given when there is a likelihood of delivery not being accomplished within two hours. It appears to have a deleterious action by inducing a tonic contraction of the uterus. The circulation in the fœtus is interfered with; in addition a poisonous influence through the medium of the blood is believed to take place."

He recommends its use as a precautionary measure in cases where hæmorrhage either before or after the expulsion of the placenta has happened in former deliveries, an admonition that may safely be followed. The method of inducing labour prematurely by douche is entered into briefly, and a remark

occurs relative to those unprincipled practitioners who unscrupulously use such means, by no means out of place. The last chapter contains some observations on anæsthesia, entering into its history, use, and method of inhaling the vapour, and the class of patients to whom it ought not to be administered.

The time at which to commence giving chloroform in labour is fully enlarged on, and will depend on the object in view. If in cases of difficult labour requiring operative interference, it may safely be laid down, that in the entire range of human suffering, there are no cases where its efficacy is greater; proving an inestimable blessing to the patient, and facilitating the efforts of the operator in the highest degree; or it may be given with the object of alleviating the pain of childbirth. In the latter case, complete unconsciousness is not desirable. The aptitude to hæmorrhage after delivery is mentioned by the use of the drugs, and, therefore, particular care must be taken after the birth of the child. It is hardly necessary to give greater praise to this little work than to add that it fully sustains the reputation of the first edition, whilst it advances the knowledge of obstetrics to the standard of the present time. The "Dublin Practice of Midwifery" is a book which every student in that art will do well to read who wishes to have a thorough knowledge of the subject.

C O C O A .

THE PUBLIC PRESS, AND TRADE ADVERTISEMENTS.

It is with some surprise that we observe such papers as the *Standard* inserting what is evidently only a trade puff as a paragraph of valuable information. If we do not take this view of the case the writer of the paragraph to which we refer is evidently writing upon a subject which he has not taken the trouble to investigate. Our attention has been attracted to this matter by the indignant protest of a manufacturer, whose refutation of the said paragraph has been refused insertion in the *Standard*. We now insert this paragraph as it appeared in that paper a few days since:—

"MARAVILLA COCOA.—Much attention has of late been called to the valuable properties of good cocoa, and to its capabilities to supersede, to a great extent, the compositions known as tea and coffee. This is entirely owing to the introduction by Messrs. Taylor Brothers of their already famous Maravilla cocoa. It is very well known to medical men that neither tea nor coffee possesses qualities that allow of the free participation, even by the most healthy, of one or the other. Dyspeptic people know what they suffer after partaking of what has become known as the "refreshing beverage," and even the strongest experience its enervating effects. The need of a good substitute for both has been for a length of time felt. The Messrs. Taylor have long studied the subject, and they can be fairly congratulated upon having hit upon a beverage that will stand the test of the most searching inquiry and of the most practical proof. The Messrs. Taylor bring this valuable cocoa from an estate in South America, which they have purchased, and they have organised a system of preparation that realises a refreshing drink quite new to the palates of the people of the existing generation. The Maravilla cocoa has had already passed upon it the encomiums of a large portion of the press of this country. All the refreshing effects attributed to tea are felt after an indulgence in the Maravilla cocoa, and—what is important—little of the nervousness and derangement of the stomach occasioned by the use of some descriptions of tea."

On reading the above paragraph only one impression can remain. The public read *as news*, that the popularity of cocoa is due to the introduction, within the last few years, by a certain firm, of a cocoa having "Maravilla" as a trade mark. That "Maravilla" will stand the test of a most searching inquiry—that there is something quite new in the system of preparation—and that "Maravilla" is the best of pure cocoas.

Now, what are the facts of the case? In a series of articles now in course of publication in this Journal upon food products, the subject of the present supply of cocoa to the British market has been carefully examined. These articles are pro-

duced *pro bono publico*, and at considerable expense to ourselves our only return having been their popularity. On reference to our analyses we find that although there are plenty of good and pure cocoas in the market, "Maravilla" is adulterated with sugar and arrowroot,—the first to a considerable amount. Perhaps it is this amount of sugar that gives rise to the statement, made in an advertisement which appeared in another daily paper, viz., that "Entire solubility" is one of its properties, &c. We find, on reference to our notebook, that the sample examined contained over thirty per cent. of insoluble matter when treated with cold water. We have not dragged the subject of "Maravilla cocoa" before the light out of any other feeling than of justice to the public and ourselves.

In justice to the public, we must protest against such paragraphs as the above appearing in respectable papers, unless there is a legible intimation that it is an advertisement. *Amor nummi* may be some kind of an excuse for the high colouring of an advertiser—not so for an editor, who, directly it appears as emanating from himself, is responsible to the public for the correctness of the matter contained therein. In justice to ourselves we must protest against what may be construed into an indirect contradiction of our report.

THE ORGANIC MATERIA MEDICA OF THE BRITISH PHARMACOPŒIA.*

THE above collection is issued in the form of a large wooden box, containing specimens in paper bags. It is got up to assist students in preparing for materia medica examinations, and really consists of (as the firm describes it) *carefully selected* and characteristic specimens of the roots, barks, flowers, fruits, leaves, resins, gums, &c., of the British Pharmacopœia, 1867. Each specimen bears a label containing a description of the source from which the article is derived, its natural order, characters, and tests, dose, and the names of the Pharmacopœial preparations into the composition of which it enters.

It contains the whole of the Materia Medica, with the following exceptions:—

Ten specimens (being ordered in their fresh state) are omitted from the collection:—*Aconiti folia*, *Armoracæ radix*, *Ecbalii fructus*, *Lactuca*, *Laurocerasi folia*, *Limonis cortex*, *Rhæadose petala*, *Rosæ caninæ fructus*, *Rosæ centifoliæ petala*, and *Sambuci flores*; but *dried* specimens of *Aconiti folia* and *Limonis cortex* are included. Of the following nine which are ordered both fresh and dried, only the dried specimens are included:—*Belladonnæ folia*, *Colchici cornus*, *Conii folia*, *Glycyrrhizæ radix*, *Hycosyami folia*, *Rosæ Gallicæ petala*, *Sabinæ cacumina*, *Scoparii cacumina*, and *Taraxaci radix*.

It is not too much to say that this collection is invaluable to the medical and pharmaceutical student, and is a prodigy of cheapness. The whole is sold for 25s., which amounts to about 2d. for each specimen. The value of the contents of the bags is in many of the specimens four times the real amount; and when we consider the care with which the collection is evidently made as regards typical specimens, it appears wonderful how it can be got together for the money. We are informed that four editions have been issued since its first appearance, twelve months ago. Nothing can speak more emphatically than this as regards its value. There can be no doubt that with a little attentive practical study with the above specimens before him, the aspirant will obtain a saving in money, time, and mental anxiety. In fact, no verbal or engraved description can replace real specimens.

Although there is some little difficulty in extending this arrangement to the other articles of the Pharmacopœia, we hope Messrs. Southall, Son, and Dymond, will be induced by their present success to issue a more comprehensive one to include the preparations. In the form of tube specimens, we think this might be accomplished. In concluding this notice we should be glad to offer a suggestion. There is a general mixed odour pervading the whole of the specimens, in spite of the fact that most of the strong-smelling ones are wrapped in gutta percha. We think this could be avoided by coating one side of the paper which is used in making the bags with indian rubber or gutta percha varnish. The odour is rather an important characteristic.

* Arranged by Messrs. Southall, Son, and Dymond, Birmingham.

Summary of Science.

By C. R. C. TICHBORNE, F.C.S., M.R.I.A., ETC.

[The Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

RECENT WORK DONE WITH THE AID OF THE SPECTROSCOPE.

It will be remembered that a great part of the Inaugural Address of the President of the British Association was taken up with a consideration of some of the spectroscopic discoveries recently made, particularly those of Norman Lockyer, Frankland, and others. In reviewing the discoveries in astronomy, he specially considered the application of the physical sciences to that branch, and divided his address into the following heads:—The velocity of light, which may be considered as the connection of optics and astronomy; the proper motion of the fixed stars; and the alteration of the refrangibility of a ray of light—and what may be almost considered as the most popular researches of the day; Huggins' researches on Sirius and determination of radial proper motion; also an account of the spectrum observations made of the solar eclipse. In reference to the last, he said that the rarity of the occurrence and the shortness of the duration of a solar eclipse afford opportunity for only a hasty study of the phenomena which may present themselves. Among them, one of the most remarkable consists of a number of mountain-like or cloud-like luminous objects, seen outside the dark disc of the moon. They have been more specially studied by the photographs made by Warren De la Rue, which photographs prove conclusively that these appendages belong to the sun and not to the moon. The photographs also prove these prominences to be remarkable for actinic power. The light proceeding from them had been examined by an equatorially-mounted telescope provided with a spectroscope, which was procured for the purpose by the Royal Society, and was entrusted to Lieut. Herschel, then about to proceed to India, one of the countries crossed by the line of the central shadow.

Afterwards it was discovered that these prominences could be traced with the aid of the spectroscope itself.

By these investigations it was proved that they were not clouds—in the strict sense of the term—but shining by virtue of their own heat, or by light reflected from below; they must consist of incandescent matter in the gaseous form. One of the most striking results of the habitual study of these prominences is the evidence they afford of the stupendous changes which are going on in the central body of our system.

APPLICATION OF SPECTRAL ANALYSIS TO PHARMACY, &c.

Although perhaps not so ambitious a flight in connection with spectral work, the paper lately communicated to the Pharmaceutical Society is of importance. The value of this practical line of investigation cannot be underrated. The ground has been vigorously broken by Mr. Stoddart. We have in this case to do with absorption spectra. The author chiefly deals with the tinctures of the pharmacopœia. "It cannot be doubted," he says, "that the use of the microspectroscope is most valuable in many analytical researches." It must not be expected, however, that every mixture will show separately the several constituents by their individual peculiarities. This is only true in a few instances. Cochineal may, for instance, be instantly detected in tinct. cardam. co. and tinct. cinchon. co. The spectrum of the biennial henbane differs from that of the annual. Thus the biennial, the violet, and two-thirds the blue of the spectrum are absorbed. The green is darkened and extended to the yellow. This handsome spectrum is crossed by four distinct lines. The first is a dark chlorophyll band at B; the second, just beyond D, is narrow; the third is a much stronger one, at E; the fourth is a very broad dark band, at F, at the commencement of the blue.

Annual.—This spectrum is very different to the last, and cannot be mistaken for it. The chlorophyll line at B is not so decided, and the second and third lines are so weak as to be barely visible, and the fourth is absent.

ABSORPTION BANDS OF BILE.

Dr. Andrews sent a communication to the British Association in which it seems that bile gives rise to a series of

absorption bands, which are distinct from those exhibited by blood. A solution of bile in water, or alcohol, exhibits in the spectroscope well-marked absorption bands.

The bands may be used as a characteristic test for the presence of bile, and even as a means of estimating, approximately, its amount in urine and other liquids having no absorption bands of their own. It is self-evident that it would be particularly useful in the practical examination of the last-named fluid.

GASES GIVEN OFF BY CRYPTOGAMIC PLANTS.

The fact that ammonia is given off by mushrooms during their growth has lately been re-examined by Dr. Lehmann. Alexander von Humboldt stated that they gave off both ammonia and hydrogen. So decided is this, that on bringing a glass rod moistened with muriatic acid near a vigorously growing mushroom, there appeared a volatile vapour, evidently due to the formation of chloride of ammonium.

Different species of mushrooms, according to the carefully conducted experiments of M. Borscow, give off, when growing vigorously, weighable quantities of ammonia. The elimination of ammonia is not confined to the full-grown mushrooms, but is found in the young plants, and even in the spawn of certain species. There is no direct relation between the quantity of ammonia and carbonic acid given off during any given period of time.—*Journal de Pharmacie et de Chimie.*

TEST FOR BRUCIA.

M. Colton recommends the following:—When to a solution of nitrate of brucia hydrosulphide of sodium is added in the form of a concentrated solution, the solution becomes first violet, next green, providing the brucia is in excess. Morphia does not give this reaction. Diluted acids render it rose colour, while sulphuretted hydrogen is given off. Two milligrammes of brucia impart in this manner a colouration to half a litre of water. We, however, already possess some valuable and good tests for brucia.

"SWEET QUININE."

Under this name a preparation is in use in America, which, according to Prof. Procter (*American Journal of Pharmacy*), is an imposition. That gentleman finds that it does not contain any quinine at all, but is mainly cinchonine precipitated from the sulphate, dried, and triturated with impure glycyrrhizin, prepared from liquorice root. The tastelessness of "sweet quinine" is simply due to the insolubility of cinchonine. That alkaloid requires 4,000 parts of cold water. When treated with acids which produce salts, or with a solvent, such as alcohol, its bitterness becomes apparent at once.

SOLUBILITY OF CARBONATE OF LIME.

M. Cossa has been trying experiments to prove Professor Bischof's hypothesis, that the state of aggregation had a great influence on the solubility of this salt. One thousand parts of water saturated with carbonic acid at atmospheric pressure dissolved of carrara marble 1.81 parts, at a temperature of 7.5° to 9.5°; .9487 parts at a temperature of 20.22°; chalk, .835 parts; precipitated carbonate of lime, .95 parts; oölitic limestone, 1.252 parts; dolomite, .573; these three last being at a temperature of 15°. The reading of the barometer at the time of the experiments varied from 7.5° to 28°.

SINDOR OIL AND SINDOR BALSAM.

These substances are said to be most valuable in skin diseases. They are extensively used by the Javanese. The balsam should have, if genuine, a sp. gravity of .922, and boils at 225°. It strikes a blood-red colour on being brought in contact with sulphuric acid.

HYDRATE OF CHLORAL.

When dry chlorine is passed through perfectly pure alcohol a substance is formed which has been named by Liebig chloral. This product absorbs moisture on exposure to moist air, and forms a crystalline hydrate, which is very soluble in water. It may also be viewed as trichloretted acetic acid, and is likewise formed by the action of chlorine upon starch.

Hydrate of chloral, when decomposed by soda, yields chloroform and formic acid thus—

It is supposed that when this hydrate of chloral is injected into the body it is gradually decomposed in the alkaline fluid, and chloroform is produced. A solution made with an equal quantity of water has been used. The largest quantity yet given has been four grammes of the solution, equal to twenty-one grains of chloroform. Drowsiness comes on, and soon perfect stupor; the effect is said to be mild and gradual. This death-like stupor was prolonged, according to the strength of the dose, as far as eighteen hours.

THE DIAGNOSIS OF CHANCRES.

DR. A. C. HAYNES gives the following differential diagnosis of chancres in the *Nashville Journal of Med. and Surg.*, culled from the best authorities.

Constitutional Chancre.

1. It has an incubation of about twenty-five days.
2. It comes first from the direct application of the virus of a constitutional chancre. Second, from secondary accidents in a secreting form. Third, sometimes from the blood of a syphilitic person in the secondary period.
3. It occurs most often alone.
4. It will not inoculate itself on the individual who bears it, nor on a person who has the constitutional syphilis.
5. It does not begin with a vesico-pustule, but by a simple erosion, and sometimes by a papule.
6. The constitutional chancre presents itself under the form of a superficial ulceration with edges inclined. This ulceration is covered, in part, by a false membrane, which resembles, in a very marked degree, the spawn of a frog. The borders are of a lively red, the form of the ulceration is generally regular; it suppurates a little.
7. It is rarely painful.
8. It is accompanied, ninety-nine times of a hundred, by an induration at the base; elastic, chondroide induration, having no characters of inflammatory induration.
9. The lymphatic ganglia in the neighbourhood of the chancre become indurated and enlarged, hard, and indolent, having no tendency to suppurate.
10. The constitutional chancre produces but very little reaction; has a great tendency to heal; it ulcerates but little, and seldom ever takes on the gangrenous or phagedenic form; it has a very regular march.
11. It is the first apparent manifestation of the syphilitic diathesis; it is then the sign of the general infection of the economy; we sometimes see the roseol, angine, &c., appear before its complete cicatrization.
12. It belongs especially to the human family.

Local Chancre.

1. It has no incubation.
2. It comes from the contagion of a local chancre or a virulent bubo.
3. It is generally multiple.
4. It is inoculable, *ad infinitum*, to all individuals, including the one who bears it. The pus from the suppurated bubo is inoculable only when it is virulent.
5. It begins with a vesico-pustule.
6. Presents itself under the form of a deep ulceration; the bottom is filled with a species of organic detritus mixed with pus. The borders are as if cut perpendicularly, separated from the adjacent parts.
7. It is nearly always painful.
8. The local chancre is generally accompanied by inflammatory induration, but never by specific induration.
9. It is nearly always accompanied by adenitis in a suppurating form, and sometimes furnishing inoculable pus.
10. It is a very grave local lesion; has a very strong tendency to ulceration; very irregular in its march; has no tendency to heal as the constitutional chancre; it sometimes takes on the phagedenic and gangrenous forms.
11. It is purely a local accident; has no connection whatever with syphilis.
12. Transmissible to some animal species.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, OCTOBER 27, 1869.

THE ARMY REPORT*.—No. 3.

THE Health of the Troops serving in the Mediterranean is the next heading. At Gibraltar, the average strength of the troops during the year was 4,555; there were 3,234 admissions into hospital, and 29 died; also 6 persons sent to Netley died; total, 35. Continued fever was more than twice as prevalent as in 1866, from the occurrence of a fever resembling the dengue fever of the West Indies. About two-thirds of the inhabitants of Gibraltar suffered from it. Enthetic diseases were more prevalent, and especially syphilitic. The deaths per 1,000 were 8·67 as compared with 9·18, which occurred in the seven previous years on an average. The Surgeon-Major of the 75th Regiment alludes to “defective drainage being the cause of typhoid fever in the Buena Vista Barracks; and among the causes of phthisis pulmonalis the Surgeon-Major of the 78th Highlanders enumerates over-crowding and bad ventilation.” In Malta, the average strength of the troops was 4,919, and there were 119 deaths—100 in and 19 out of hospital; the admissions thus being in the ratio of 863, and the deaths 24·19 per 1,000 of the strength. This is a terrible death-rate, and far above the average rate in Malta. Continued fever prevailed to a great extent from June to September, and proved very fatal. Spasmodic cholera, also, prevailed to a great extent in the early part of the summer, in Sicily and Turin. The annual death from tubercular disease was very low, namely, 1·86 in 1,000. Probably, fever cut off some of those who would have succumbed to this more chronic disease. Inspector-General Paynter says, in reference to the opinions of the different Medical Officers, that he is disposed to consider that drinking to excess has been a fertile cause of disease. With regard to invaliding from the Mediterranean, it seems that 221 invalids were sent to England, and 143 finally

discharged the service at Netley during the year, being 23·3 and 15·1 per 1,000 of the mean strength.

The next heading is, the Health of the Troops serving in British America. There were, in 1867, 11,240 men serving in Canada, and the death-rate was 9·87 per 1,000 of the mean strength. There were 10 in 1,000 admitted into hospital, and 1·42 deaths from tubercular diseases in the same year. Enthetic diseases were more prevalent than in former years, especially primary venereal sores. There has been no difficulty in getting the requisite quantity of cubic space for the soldiers, except for a short time in winter. The health of the troops at Nova Scotia and New Brunswick seems also to have been excellent. In Newfoundland, there were 280 troops, who had a high death-rate, namely, 17 in 1,000. The occurrence of drunkenness seems to be very frequent in Newfoundland; one man, poor fellow, was frozen to death near the barracks. In Bermuda there were 1,249 men in 1867. The death-rate was high: 17·61 per 1,000. There were 11·2 admissions per 1,000 into hospital for phthisis, and only 0·80 deaths per 1,000 from other causes. Continued fever furnishes less than half the average proportion of cases, and there were four cases of yellow fever admitted into hospital, of which three terminated in death. The troops were immediately removed from the barracks when the deaths took place, and consequently no more were attacked, except the orderly, who was left at the hospital. This points to the value of quarantine in cases of yellow fever. The cases were attributed to the noxious exhalations from the military cemetery, which was close to the forts.

The Health of the Troops serving in the West Indies is next reported upon. Continued fevers were below the average in 1867.

Yellow Fever.—On the 5th October, an officer of the 16th Regiment, just arrived at Barbadoes by the mail steamer from Halifax, *via* St. Thomas', where he had been ashore for 36 hours, and when yellow fever was prevailing, was attacked by the disease and died on the 8th. And, note! on the 31st, an Ensign of the same Regiment, occupying quarters on the upper floor of the Brick Barracks, closely adjoining those in which the first case died, was attacked, and died on the 7th November. We suspect our readers will be inclined after such cases to admit that yellow fever is contagious. There has been an increase in the quantity of enthetic diseases, principally at Barbadoes, which, with Trinidad, were the only stations in the Windward and Leeward Commands occupied by white troops. There were 603 black troops in the Command, and they appear to have suffered greatly from enthetic diseases, as also from diseases of the tubercular order. The surgeon of the 4th West India Regiment hazards the assertion, that the prevalence of consumption among the black troops is in a great measure to be attributed to “the venereal poison acting on a constitution weakened by sexual excesses committed at a very early age.” We rather suspect that this, like many other of our medical guesses, is only an hypothesis. At Jamaica, there were 788 troops in 1867. The death-rate was excessive, amounting to no less than 71·07 per 1,000 of the troops. There were no less than 114 cases of yellow fever, of which 48 died per 1,000 of mean strength. There was also much remittent fever. Dysentery and diarrhoea were considerably above the average, and enthetic diseases much below the average of ordinary years among the white troops. There were 722

* Army Medical Report for the year 1867. London, 1869. Pp. 563. London: Harrison and Sons.

black troops, and their death-rate in the year was only 29·08 per 1,000. Tubercular diseases were more fatal than usual among the black troops. As much as 31·9 per 1,000 were admitted into hospital, and 8·31 died of phthisis. Indeed, tubercular disease is reported to have caused one-fourth of the mortality among the blacks.

Port Royal was occupied by white troops from January to April, during which latter month cases of yellow fever occurred in the men of the Royal Artillery, and their removal to Newcastle was recommended. The disease was prevalent among the seamen in Port Royal Harbour, but was not at the time epidemic on shore. The removal was very successful, no other death occurred, and only two cases of the disease were treated at Newcastle during the stay of the battery there. Port Antonio has been occupied by 27 men and one officer—3rd West India Regiment—and a Staff-Assistant-Surgeon; the latter died of yellow fever. In the Bahamas, there were only 14 white troops stationed in 1867. There were 392 black troops, however, among whom enthetic diseases seem to have been very prevalent, and tubercular disease continued to furnish a high rate both of admissions and of deaths. The Medical Officer attributed their prevalence to over-crowding of the barracks, and to defective ventilation. In Honduras there were only 11 white troops, and 363 black men. Enthetic disease is again mentioned as being very prevalent, in the form of primary syphilis. During the year 1867, there were 37 of the white troops invalided to England from the Windward and Leeward Command, and 17 from Jamaica; and there were 69 of the black troops serving in the West Indies and Western Africa discharged the service as invalids during the year, being in the proportion of 22·29 of 1,000 of the strength employed in the Colonies.

SANITARY MEASURES AT BRISTOL.

MUCH prominence has lately been given to the sanitary measures which have, it is asserted, changed Bristol from one of the unhealthiest to the most healthy town in the United Kingdom. The *Times* has devoted several columns of its space to the sanitary state of Bristol; and if all the statements made can be substantiated, the inhabitants deserve to be congratulated on their condition, and the gentlemen who have worked so heartily in the cause on the success of their plans. All that has been accomplished is compressed within a brief period; indeed, five years have seen the change from nearly the bottom to the top of the list, and no one can deny the importance of such a case. If Bristol is saving a thousand lives a year, how many hundreds of thousands of lives are being lost in other towns of the British Empire for want of that vigorous action which has been rewarded with such magnificent results? Dr. Budd and Mr. Davies, and, in fact, all concerned, have worked with hearty good will, and, whether all their theories are eventually proved correct or not, their practice claims the grand merit of success.

The Profession is well aware how much importance Dr. Budd assigns to contagion—a doctrine old enough to have numbered many enemies whose counterblasts may, to some extent, be responsible for a certain degree of carelessness in quarters where negligence is least excusable. The main point of Dr. Budd's teaching is that the contagious principle is material, and may be effectually destroyed. The aim of his practice is to destroy it as it issues from the body. It is of little moment whether the

theory be preferred to that which ascribes the development of contagion to chemical changes of secretions after they have left the body or not. Either case is met by the destruction of such secretions at the earliest possible moment. What boots it if a material capable of spreading disease be decomposed or prevented being formed? The great thing is to act upon it, or the elements capable of producing it, the moment they come within our reach; and this has been the one great aim at Bristol. Few will be disposed to deny that equal promptitude and energy might everywhere prevent much suffering by diminishing both sickness and death—for the mortality returns tell but a tithe of the great hygiene battle.

Between 1851 and 1864 Bristol constructed its sewage system, and brought water from the Mendip Hills. There was henceforth no possible contamination of the drinking water with sewage matter. Still typhus raged throughout the latter part of 1864, and thus clearly proved that all epidemics do not originate in such contamination. Nearly 2,000 cases should suffice to prove that some diseases should be looked for outside the water-cistern, in spite of the fœn of one idea. By strict disinfection the calamity was met and at last got under, and the health of the town has been improving ever since.

By strict disinfection we do not merely mean the use of chemical agents in water-closets and drains: this is only one element in the case. The greatest care was taken to prevent the accumulation of filth in the courts and alleys. The surface drainage was never neglected. Inspection was constantly carried out by a large staff of energetic men under the direction of those who believed in their power to prevent disease. The people were visited, talked with as friends, instructed in the importance of the utmost cleanliness, urged to assist the officers in their work; above all, whenever a case of zymotic disease occurred efforts were redoubled, and the necessity of destroying by chemical means the secretions of the patient as they issued from the body was urged upon all concerned with a pertinacity that amounts almost to an enthusiasm.

The result of this care forcibly illustrates the value of sanitary measures, and should stimulate places that have no medical officer of health no longer to delay making such appointments. When we reflect how few such offices exist, how the masses of our countrymen are living with no intelligent professional guide to direct the resources of medical knowledge so as to ancliorate the evils of civilization, how few even bestow a thought on the prevention of disease, how dense is the ignorance of the simplest laws of hygiene—we are tempted to exclaim that all the questions that have agitated political circles of late are of less import to the nation than the one great question of public health. Whatever we may think of the theories propounded at Bristol, we cannot too strongly urge other towns to follow the example that has been set.

A CHEAP GRUBKILLER.—Cauliflowers, broccolis, and other brassicaceous plants are generally much infested with grubs at this season. To clear them off is an easier task than it appears. Dissolve a coffee-cup full of salt in hot water, then put it into a common-sized watering pan, and fill up with cold water. Just give each plant a gentle switch over with this mixture, and they will all disappear in a moment, and the salt and water will nourish the plants wonderfully. All greens are fond of salt and water. Some people would be afraid of killing their cauliflowers; but it must be borne in mind that the salt and water will not penetrate the leaves. It runs off to the roots, killing every caterpillar in its way.—*Gardener's Magazine*.

Notes on Current Topics.

St. Bartholomew's Hospital.

THE Royal Hospital may yet emerge from its unsatisfactory condition. The whole Press has, as we have already shown, turned the light of publicity on the doings at Smithfield; and, the pertinacity of the obstructive party notwithstanding, the abuses that have too long disgraced the whole hospital system must be remedied. Three years ago we singled out the management of St. Bartholomew's as specially to be condemned, and urged upon the governors the necessity of enlarging their staff. A little later we exposed the hollowness of a pretended creation of departmental study which was announced with a flourish of trumpets that might have heralded a real reform, but which consisted in referring certain specialties to the care of overworked members of the staff. The obstructives triumphed, but we knew it was only for a time, and we calmly awaited the inevitable explosion. It has come, and is making more noise than the sage wiseacres would believe. Selfishness will not always succeed, and we rejoice at its ignominious failure now. There are plenty of "good men and true" worthy of posts on the permanent staff—aye, who ought to have had them long ago, but have been kept out in the cold, while the work they would gladly have done has been worse than undone, for the gigantic sham of prescribing at the rate of more than 100 per hour has still gone on. For years we have urged that a large increase of the staff was needed at all the larger hospitals to cope with the work, and to render it available for teaching purposes. At length our cry is adopted; the public has pronounced, the general press endorses our views, and only a few individuals breathe a word against the long-needed step being taken. It is something that such a power as the *Times* should be with us. In a powerful article last Friday, that journal, after lashing the authorities as they richly deserve, speaks decisively in favour of increasing the staff as the one thing wanted. Gladly we welcome such an ally in the war we have been waging, and urgently we plead with the *Times* that other hospitals too, if not in the same degree, yet urgently need the same measure. Everywhere the larger hospitals are laying on the shoulders of their staff a double burden, and nowhere is there any plausible excuse. Everywhere ardent workers are fretting their best years away, waiting to be employed.

The suggestion of a superintendent is as useless as it is strange from the quarter which once so strongly denounced such an officer.

The Late Lord Derby.

LORD DERBY, who had lingered for ten days after his recovery became hopeless, has passed away. At the close he was unconscious, and therefore, happily, not suffering. He died, in fact, from exhaustion caused by another attack of his old enemy, the gout. To the country generally, his case seemed to be very lingering—a feeling produced by the intense interest felt in him by men of all parties. We have the liveliest recollection of the oratory of the "Rupert of Debate," and the greatest respect for the memory of one who only took office when he felt it a duty to his country, and whose virtues were worthy of his great position.

Royal College of Surgeons of England.

MR. ERICHSEN has begun his career as a Councillor in a manner that seems likely to redeem his promises as a candidate. This is great praise considering the atmosphere into which he has been elected. We believe in Mr. Erichsen's sincerity, and therefore we are glad to announce that he has given notice of his intention to propose an alteration in the bye-laws of the College, with a view to permitting the Fellows to meet within its walls. The question will come on next month, and if Mr. Erichsen succeeds, he will have won his spurs as the champion of the rights of the Fellows.

The London Schools.

THE official report shows that at the eleven schools of medicine in London 1,231 gentlemen are pursuing their studies. This is three more than in 1860, the year of the "rush" to escape the new preliminary examination. The freshmen are 96 at Guy's, 80 at St. Bartholomew's (notwithstanding the dissatisfaction that exists), 71 at University College, 33 at King's College, 29 at the London Hospital, 28 at St. George's, 28 at St. Thomas's, 16 at St. Mary's, 15 at Middlesex, 7 at Westminster. Charing Cross boasts of 18; but when we consider that there are arrangements at that school for free scholarships, and that the teachers have some privileges of introducing pupils who cannot pay the usual fees, it can scarcely be called in flourishing condition.

There are, we believe, at some hospitals a few who have not yet registered, and one or two others who only enter for partial instruction. Moreover, it is confidently stated that the official list is not nearly complete.

Still St. Pancras.

MR. GOSCHEN has decisively snubbed the St. Pancras Guardians, headed by, we regret to say, a medical practitioner. In so doing he has done public service, and by refusing to restore to them the power of dismissing their servants shown that his estimate of their fitness for such a position as they occupy is just that of the general public. Among the silly things said at the deputation by the medical spokesman was a complaint about inquests being held and the medical officer receiving a fee for giving evidence. Fancy a lawyer protesting against a member of his profession being paid! It is thus that the Medical Profession is brought into contempt.

We rejoice that Mr. Goschen has proved himself a strong Minister, with a will of his own. Such a man has been long wanted at the Poor-law Board. When he took the office of President, almost alone in the Press, we predicted that he would succeed. In this St. Pancras business he has shown that he has the true metal.

A New Double Diploma.

THE Royal College of Surgeons of England has been roused from its apathy by the spirited action of the Royal College of Physicians of London. The latter body has, as we have previously reported, issued a complete licence in Medicine, Surgery, and Midwifery. The licence has been recognized, and Lincoln's Inn brought to reason by a fear that its occupation is gone. The probable loss of fees seems to have roused the College of Surgeons, which was insensible to every other consideration, and it now pro-

nounces for a joint Examining Board. To the Profession it is of little consequence whether the sister College will accept the advances now made by those who so long refused to reciprocate. If Lincoln's Inn can join with Pall Mall, well and good. If not, the licence from Pall Mall being recognized as a complete diploma lands us at once on the one faculty system, and will relieve half our grievances. Let English students all take the L.R.C.P. Lond., and nothing else, and they have enough. Scotland is working its double diploma very satisfactorily. Clearly we are making progress.

Work me to Death and I will be Grateful.

THAT should be the motto of Poor-law medical officers, and, we grieve to say it, it is too generally followed. Let us record, however, our thanks to a gentleman who has resigned his appointment, with the courageous statement that "he could not thank the Board for their kindness." This was Dr. Timothy, who, in the Shoreditch Union, was paid at the handsome average of 5s. 3 $\frac{1}{2}$ d. a day for the trifling work of giving professional attendance to six-and-thirty paupers! Dr. Timothy said something about "throwing off a martyrdom," and he is clearly unfitted for the post. He forgets that if his wages were less than a bricklayer's he had the honour of being looked down upon by the Guardians. One of these said that others were anxious to get the place at the same money. Of course. The Medical Profession always was full of men anxious to become martyrs, and ready to work themselves to death to prevent others enjoying the same luxury. Here is a chance for one! Nor is this the only chance! To the disgrace of the Profession, which despises union, a chance has already been missed, and the Spalding Guardians have not found anyone ready to jump at the offer of £45 per annum for the vacant district of Gosberton, with a population of only 3,400, and an extent of area of only 13,000 acres! Surely there is a grand mistake somewhere. Some holder of two diplomas, each of which is supposed to stamp a man as an educated gentleman, must be waiting for such a golden opportunity of "going about doing good," and there would surely be some *going about* even over only 13,000 acres.

We suppose the explanation must be that those in want of work think a population of 3,400 too small to attend for £45, and disdain to take an appointment that their brethren might fancy to be a sinecure. Still, in the present overstocked condition of the Profession, when so many hundreds cannot get a fair chance of sacrificing themselves, we think that it is not necessary to refuse any longer on this ground.

Having paid for the "one straw a day," which we suppose to be the usual diet in such cases, and discharged the rates and assessed taxes—*income-tax* would not be required, it will be noticed—it would be quite in the power of the lucky man who gets this berth to die at his post; and he need leave no will, as the landlord would lawfully take any balance in his house towards the rent. We shall have much pleasure, when these appointments are filled up, in contributing to the immortality to which men who accept them will be entitled, by printing their names and qualifications in full, if they will have the goodness to supply them.

Railway Reform.

THERE is some hope that our railway system may be

rendered less costly, less dangerous, and less inconvenient. What with "bogies" and other contrivances, shareholders and travellers may both take courage. The great thing is to rouse directors from their apathy. Of all promises that of Mr. Jones, who gives us a plan of universal penny railways, is the most striking. We have a penny post, penny papers, and almost penny everything. We are growing a penny-wise people. The almighty penny will soon replace the "almighty dollar," and if Mr. Jones's plan give us a penny railway journey, that will be a great step in our progress. But can such a thing be done without enormous loss? Mr. Jones says Yes, not only without loss, but with a handsome profit. How, is fully detailed in his pamphlet, which those interested can consult.

Scarlet Fever.

THIS disease is still on the increase in London. There were 224 deaths in the week ending the 16th. The disease is also excessively fatal in other large towns.

The public press naturally takes notice of such a state of things. One result is a number of silly suggestions. M. D. writes to the *Times* to laud belladonna, and says that numbers of parents had employed it after reading a former letter of his.

This is not professional, nor does it tend to public good. Most medical men know how much and how little belladonna can do. But that is not the point. A public journal may be a proper medium for discussing disinfection, or how to prevent in any way the spread of a disease. Treatment should be left to professional men, and its discussion to medical journals.

Cruelty to Horses.

ONCE more an indignant cry has been raised against the cruelty involved in compelling horses to pound down the granite with which the roads are mended. There is a steam roller in London, but it is for the use of Hyde Park. Why are there not half a dozen? In Paris we have seen a road made as level as a dining-room floor, at a trifling cost, by means of a roller that did all the work between the hours of 3 and 5 A.M. In London, especially just at this season, the visitor may any day see fine horses ruined, and the unfortunate animals who draw cabs, omnibuses, and other heavy loads, straining their weary muscles in the vain attempt to overcome the difficulties that road menders should be punished for creating. It is a sad, sickening sight, disgraceful to the British Empire.

Cholera and the Sanitaria in India.

It has been officially announced that cholera has disappeared from Allahabad, and that all the western districts of the North Western Provinces continue free from it.

The 58th Regiment is said to have lost upwards of one hundred lives by the epidemic with which it has been so long afflicted.

The *Delhi Gazette* announces that the Sanitary Commissioner of the Punjab, Dr. De Renzy, has instituted, or is about to institute, a suit against *Indian Public Opinion* for libel said to be contained in an article on the sanitation of Umritsur in the issue of the 17th of August. Damages are to be laid at 10,000 rupees.

It appears from the tables placed at our disposal, that cholera carried off in Umritsur no fewer than four hundred and ninety-three persons between the 15th and 31st July, both dates included, or at the rate of twenty-nine per day, and that between the 1st and 29th of August there have died the enormous number of *two thousand two hundred and forty-four* persons, being at the rate of a fraction over eighty per day. During these same forty-five days there have died five hundred and sixty-six persons from fever and one-hundred and sixty-five from other causes, showing a total of three thousand four hundred and sixty-eight, or eighty-one and a fraction per day for these forty-five days, the ordinary death-rate of the town of Umritsur being under eleven per day, showing that during the period under review there have occurred *seventy* deaths per day over the ordinary rate, or three thousand one hundred and fifty in all.

The *Mofussilite* condemns the sanitarium at Subathoo :—Why the place was ever chosen as a sanitarium, or for a European cantonment—considering how other sites, preferable in every respect, might have been selected—almost passes comprehension. It is virtually a locality without a single special recommendation adducible in its favour. Yet as a sanitarium it has proved a miserable failure—a very fatal one. The 90th Light Infantry, when stationed there the year before the last, suffered most severely, and now the 41st Regiment has come in for its turn of the suffering. The senior captain of the corps has died in camp, and a fortnight ago the senior lieutenant died, the paymaster's daughter, Miss Simpson, dying about the same time. Five officers of the corps are at home or on their way home, on medical certificate, and during the late outbreak of cholera there were numerous cases, at least ten or twelve of which proved fatal. Then thirty-seven soldiers' children have died at Subathoo since the regiment went there last December. This great mortality amongst the children has for one assignable cause the impossibility of procuring at the place necessary infantine nourishment; the soldiers' wives might as well expect warm clothing for nothing as in Subathoo look for a good supply of good milk at any price! The *Pioneer* hears from Subathoo, under date the 15th ult., that, owing to one or two cases of cholera in the 41st Regiment, one of the camps had been ordered to change its ground.

Gratuitous Medical Services in the Indian Army.

A QUESTION was recently raised regarding the title of military officers and chaplains visiting a hill sanitarium to gratuitous medical attendance, and authoritative ruling was requested as to the persons entitled, when residing at such stations, to the privilege for themselves and their families. In reply to this reference the Government of India quoted a former decision on a similar reference, under which the families of chaplains and assistant chaplains, wherever they may be in India, are clearly entitled to be attended gratuitously by the medical officers of Government. It was added that this ruling holds good whatever be the circumstances under which an officer and his family are resident at a hill station, and further that all officers and their families, who are entitled to gratuitous attendance in a cantonment or civil station, are entitled to it at any other place where there is a medical officer paid by Government for staff or general duties.

Clerical Patrons of Venereal.

FREE trade in syphilis is the novel principle which certain clergy, under the leadership of a Dr. Charles Bell Taylor, have taken under their protection; and we are enabled, at least, to congratulate the Church on the ample field for their crusade which the subject affords them. In the Public Health Section of the Social Science Congress, Dr. Berkeley Hill had communicated the statistics of the working of the Contagious Diseases Act. He was followed by Dr. Taylor *contra*, and a scene followed, which is thus described by the *Times'* reporter :—

“There then followed a scene of great confusion and disorder. A large number of persons, many of them apparently clergymen, had come to the meeting for the express purpose of protesting against the Act. In debate the advocates of both sides waxed warm, and the enthusiasm of those who fancied they saw in physical disease a Divine judgment against moral transgression was obviously much in the ascendant over the calmer views of more reasonable men. Excited gentlemen in white cravats surged tumultuously over the benches, vociferated, half a dozen at once, set the Chairman to rights about his ruling on points of order, and loudly applauded whatever seemed to tell in favour of their views. At length, after a time probably without parallel in the history of science congresses, and after resolutions and amendments had been put and stormed over, a resolution in opposition to the extension of the Act was carried by about two to one in a meeting of rather more than 100.”

Cannot the vaccino-maniac fraternity take powers to add to their number by the annexation of these persons? They would be as impervious to facts, arguments, or good taste as could be desired for the service; and free trade in small-pox might be consistently combined in one agitation with free trade in the larger variety.

When persons who disclaim the possession of eyes, ears, and senses obtrude themselves into an assemblage of sensible men, they may at least be not unreasonably expected to keep down their efferescence. Their theory that syphilis is to be encouraged for penal purposes is hardly worth noticing.

University of Oxford.

THE decease of the Earl of Derby causes a vacancy in the Chancellorship of the University of Oxford. The name of the Marquis of Salisbury was put forward by some Conservatives as a likely one, even before the Earl had actually expired. Others have lately mentioned the Earl of Carnarvon, who is at present High Steward. Sir S. Northcote, the Earl of Harrowby, and Lord Churston have also been named.

The Liberals will surely not let the Chancellorship pass, without a struggle, to their opponents. They could not put up a better man than the Premier. If successful, they would do what they could towards wiping away the reproach of having discarded him, and many would vote for Mr. Gladstone as Chancellor on account of his eminence as a scholar, who could not conscientiously support him as member for the University.

Health of Dublin.

QUARTERLY SUMMARY.

Births.—In the Dublin Registration District, the number of births registered during the thirteen weeks ending Saturday, October 2nd, amounted to 2,024, being equal

to an annual ratio of 1 in 39, or 26 in every 1,000 of the population. The number of births registered in the north side of the city was 825, or 1 in 33; and on the south side of the river 866, or 1 in 42; and in the suburbs of Rathmines, Donnybrook, Blackrock, and Kingstown 333, or only 1 in 45.

There were registered in London during the same period an annual ratio of 1 in 29; in Glasgow, 1 in 26; and in Edinburgh, 1 in 28.

The number of deaths registered amounted to 1,673, an annual ratio of 1 in 47, or 21 in every 1,000. The number of deaths in the northern portion of the city was 664, or 1 in 41, and in the southern portion 778, or 1 in 47; and in the suburbs 231, or 1 in 65 of the population.

The proportion of deaths registered in London was 1 in 41; in Glasgow, 1 in 37; and in Edinburgh, 1 in 37.

Of zymotic diseases, that which proved most fatal during the quarter was diarrhoea: from this disease 118 deaths resulted, being 1 in every 14.2 of the total deaths. During the corresponding quarter of last year diarrhoea caused 279 deaths. The deaths from scarlet fever registered during the quarter amounted to 94, or 1 in 17.8 of all the deaths; 80 deaths were attributed to measles, against 9 in the corresponding period of last year. Fever caused 70 deaths—viz., typhus 23, typhoid or enteric 32, and simple continued fever 15; 128 deaths were attributed to convulsions. Croup proved fatal in 16 instances, diphtheria in 4, quinsy in 1, and whooping-cough in 5. Bronchitis caused 127 deaths, and inflammation of the lungs 34; 76 deaths were referred to heart disease, 12 to aneurism, and 1 to pericarditis. Liver disease unspecified caused 29 deaths, inflammation of the liver 1, kidney disease unspecified 15, nephria or Bright's disease 8, inflammation of the kidneys 2, and inflammation of the bladder 1; 208 deaths, or 1 in every 8 of the total deaths, were ascribed to phthisis or pulmonary consumption. Mesenteric disease caused 45 deaths, and water on the brain 46; 31 deaths were caused by cancer. Accidental causes produced 31 deaths; 3 suicidal deaths occurred.

Ages.—Of the 1,673 deaths, 48.6 per cent. of the deceased had not reached their twentieth year, 37.4 per cent. were under 5, 6.2 per cent. under 10, 2.0 per cent. under 15, 3.0 per cent. under 20, 16.5 per cent. between 20 and 40, 16.1 per cent. between 40 and 60, 16.0 per cent. between 60 and 80, 2.7 per cent. had attained their eightieth year. The deaths of 9 persons stated to have been nonagenarians, and that of one person returned as 100 years old, were registered.

WEEKLY RETURN.

In the Dublin Registration District the births registered during the week ending October 16th, amounted to 162. The average number in the corresponding week of the years 1864 to 1868 inclusive, was 151. The deaths registered during the week were 138. The average number in the corresponding week of the previous five years was 150. Thirteen deaths resulted from scarlet fever, and 4 from measles. One death was caused by diphtheria. Two deaths were ascribed to typhoid or enteric fever, and 1 to simple continued fever. Croup proved fatal in three instances. Seven deaths from diarrhoea, and 1 from dysentery, were registered. Six children were carried off by convulsions. Eleven deaths were referred to bronchitis, and

4 to pneumonia. Six deaths were attributed to heart disease. Liver disease was the cause of 4 deaths, kidney disease of 1, and nephria or Bright's disease of 1. Cephalitis was the cause of 3 deaths. Eighteen deaths resulted from phthisis, 3 from mesenteric disease, and 1 from water on the brain. Two deaths were caused by cancer. Three accidental deaths were registered. A female infant was found in the Grand Canal basin—verdict of coroner's jury, "found dead." Seven of the persons whose deaths were registered during the week had attained the advanced age of 80 years and upwards.

DR. WILSON FOX is now in attendance at Balmoral.

D. T. S. has given £1,000 to the Middlesex Hospital.

THE date of the next dinner at the Medical Club has been changed to Wednesday, November 3rd.

HER MAJESTY is about to establish a medical practitioner at Craighie. It will greatly benefit the poor, who now have to send a long distance.

DR. WILKINSON, of Manchester, and Dr. Broadbent, of London, were elected Fellows of the Royal College of Physicians at an *extraordinary* meeting on the 18th inst.

BUNHILL FIELDS, the great middle-class burial ground, where rest the remains of so many of England's noblest sons, has been opened as a place of quiet recreation for the public.

MR. HUGH STOTT, M.R.C.S., died on the 5th inst. at the Royal Kent Dispensary, Greenwich, of which he was Resident Surgeon. He has left a wife and ten children, one an infant. He had practised for many years at Lewisham.

THE death from bichloride of methylene, recorded in our last, was duly discussed at the Medical Society of London. Mr. Marshall (President), who administered the agent, related the means taken to resuscitate the patient. No blame can be attached to any one in reference to the event.

THERE is no foundation for the report circulated by a home paper that Dr. Muir, Inspector-General of Hospitals British Forces in India, is going home, and that Dr. Beatson returns as his successor.

The Rangoon papers speak of cholera as raging at Thyetmyo, the frontier station of British Burmah.

WE regret to learn of the death of Dr. Dunn, of the 5th Lancers, at Lucknow, of cholera, on the 15th ult. The deceased officer is spoken of as having been one of the best doctors Lucknow has had for many years. He was noted for the assiduity and care with which he attended all in need of his advice, and more particularly for his devotion to duty during the trying time his regiment has lately passed through.

SCOTLAND.

IN our number for October 6th we gave our readers the points of Sir J. Y. Simpson's letter in the *Scotsman* in reference to the antiseptic treatment and the construction of the new Infirmary. It is to be regretted that there is so much disunion amongst the Profession in Edinburgh, as the succeeding correspondence and the reports of what passed at the interview with the managers of the new Infirmary display. Whatever the merits of carbolic acid, they are not to be increased by injudicious admirers of it vaunting the ability of one individual to apply it, nor can they fairly argue that only one person knows how to employ the remedy. Such arguments dishonour those who use them, and tend to excite suspicion in the minds of all. Nor can we see why the powers of carbolic acid could be abridged by its application being watched by another Professor. If it can more than conquer "a festering mass of corruption" in a cholera burying-pit behind the Glasgow Infirmary its virtues would surely be able to withstand the presence of an Edinburgh Professor. To say No is to say it is anti-septic as antiseptic, and relegate it to the class of spiritualistic performances. The idea of a colleague's presence influencing the effect of a remedy is only worthy of professed mediums. We trust we shall hear no more of such logic.

The following letters to the *Scotsman* succeeded the one we quoted on the 6th. It would be as well to address such communications to the medical papers:—

Edinburgh, October 1, 1869.

STR,—The letter of Sir James Simpson in the *Scotsman* of the 29th ult. is but one of a series of attacks which he has made on the antiseptic system of treatment, and on myself in connection with it.

Personally, I regard these efforts of his with indifference. The antiseptic treatment is making steady progress, both in its own development and in acceptance with the Profession; and as to my credit in the matter, I leave it to the impartial judgment of those who are conversant with the facts.

But, in the interest of the public, I feel bound to say that the statement lately made by Mr. Syme in your columns regarding the striking improvement which the antiseptic treatment has effected in the salubrity of the wards under my care in the Glasgow Royal Infirmary is strictly accurate, as shall shortly be substantiated by incontrovertible evidence.

I am, &c., JOSEPH LISTER.

52 Queen street, October 5.

STR,—Along with every true friend and well-wisher of Professor Lister, I lament that—even before he is settled in Edinburgh—he should write in your columns in such a strain of unprovoked contention and bitterness. It bodes evil days, I fear, to the Profession here. Yet, notwithstanding, he may be certain that if he has aught whatever really new or valuable to show us, it will betimes be duly accepted and acknowledged; but he must not imagine that medical men can be imperiously scolded and frowned into convictions on antiseptic or any other matters.

I have made no attacks on the use of disinfectants in surgery, as Professor Lister wishes your readers to believe. On the contrary, in a London medical periodical of last week only, I recommended the extension of experiments with various surgical antiseptics, old and new, that were therein named.

But the real front of my offending is, I believe, something different. In 1867, when Mr. Lister first began writing on surgical antiseptics, I took the liberty of showing him—first orally, but without success, at Dublin, and afterwards in a communication in the *Lancet* of 2nd November, 1867—that he was strangely, and to my mind most unaccountably wrong, in considering as his own the discovery or employment in surgery of one excellent disinfectant—namely, carbolic acid. For, years previously to the above date, books and papers had in France, Germany, and Italy been already published on carbolic acid in surgical practice (and with exactly and precisely

that same germ or spore theory of its action which Mr. Lister subsequently advanced as entirely original on his part); its use had been introduced into various Continental hospitals; and, above all, accounts of it had been, from time to time, duly given in all our leading British medical journals. In consequence of thus daring to maintain the just and indisputable claims of our Continental brethren to priority in this matter, I have incurred, it now appears, the high displeasure of Mr. Lister. But that a young and zealous teacher of surgery should be wholly unacquainted with the preceding well-known facts in the literature and progress of his art, and particularly on a subject which he was professing specially to study, seems to me almost incredible; while, on the other hand, it appears still more incredible to suppose that, knowing them, he should, against that spirit of candour and honour which is the pride of British surgery, have calmly attempted to appropriate the published thoughts and discoveries of others. Nevertheless, Mr. Lister may rest assured that, if I had not felt in a manner driven by him to point out his proceedings in this respect, they would have been denounced betimes, and perhaps far more harshly, by other pens; for there is a rectifying *vis medicatrix* in surgical history as well as in surgery itself; and even the most exaggerated misstatements ever ultimately fail either to form the facts or alter the dates of science.

I am, &c., J. Y. SIMPSON.

GLASGOW AND ABERDEEN UNIVERSITIES.

THERE are two candidates in the field—both lawyers. Mr. Gordon is Conservative, and Mr. Archibald Smith, Liberal. Neither put forward any programme of medical reform. A meeting of medical graduates took place last evening—too late for us to give particulars this week. In reference to the Irish land question, Mr. Archibald Smith says, some improvement may be effected in the law of real property, and that of landlord and tenant in particular, and the attempt must be made. He is not opposed to compulsory education provided it is not extended to the inculcation of particular religious views; and is in favour of throwing open the Universities. Mr. Gordon is in favour of an extension of the national school system of education, and to the principle of compulsion where necessary. With regard to the land question, he says a general system of leases, such as prevails in Scotland, would probably be the best protection both for landlord and tenant; but if that is unattainable, at least immediately, he would be prepared to support a measure giving reasonable compensation to the tenant for what are truly permanent improvements.

DR. ARTHUR GAMGEE, F.R.S., has been elected to the Chair of Physiology at Surgeons' Hall.

AT Leith the mortality returns are very unfavourable. Scarlet fever and typhoid appear to be prevalent.

DRS. ANGUS FRASER, KERR, AND BRUCE have been elected to the vacant Examinerships in the University of Aberdeen.

THE returns from Glasgow still show a high death-rate, and at the Fever Hospital the percentage of deaths has increased.

NEXT Friday, 29th, is to be held the half-yearly meeting of the General Council of the University of Edinburgh when the resolution of the University Court to admit ladies to medical study in the University will be submitted for approval. The Rev. K. M. Plinn, D.D., will move that the General Council disapprove of the resolution of the University Court.

EXTERN MATERNITIES AND LYING-IN HOSPITALS.

A REPLY TO CRITICISMS ON A COMMUNICATION TO THE DUBLIN OBSTETRICAL SOCIETY.

By EVORY KENNEDY, M.D., F.K.Q.C.P.

(Continued from page 327.)

I FEEL convinced, Sir, that you and this Society will agree that I have occupied sufficiently your time in dealing with individual criticism, and that you will be prepared, at this stage of our discussion, to expect me to deal with the subject generally. We shall therefore ascend *de particulare ad generalem*. In doing this I should mention that I attempted to draw out a tabulated calculation of the opposition and support given by the members who have spoken on the debate, and I find, as nearly as I can calculate, that in dealing with my thirteen propositions, the 16 speakers expressed 76 opinions. That would arrive at very nearly an average of 5 opinions each proposition. Of these 53 supported the propositions and 23 opposed them, or supported their converse. But this gives us little information of how far they supported my views, or what views exactly they supported and what they opposed. I am sure I shall be excused in making this analysis when I say, although many of my critics attacked me and the proposed changes I advocated, most of them were fain to admit the basis upon which my arguments were fixed, whilst they objected to my conclusions and remedies for grievances as patent as the sun at noonday.

We shall give one example of this which will apply equally to several other of my propositions. Ten gentlemen freely admitted metria as contagious. But, Sir, it must result from the simplest process of reasoning that every gentleman who has admitted the contagious nature of metria, in however small a degree, must, as a matter of course, and, as a consequence of the admission, agree in the truth of twelve of my thirteen propositions, including the three conclusions resulting from them. Let us just test them *seriatim*.

Proposition No. 6.—It is contagious consequently.

It is contagious consequently.

It is contagious consequently.

It is contagious consequently.

It is contagious consequently.

It is contagious consequently.

It is contagious consequently.

Proposition No. 1.—It is due to dissemination of poison.

Proposition No. 2.—It is absorbed into the system either of the generator or of another parturient exposed to its influence.

Proposition No. 3.—The generation or spread must be in proportion to the number of parturients exposed to the poison.

Proposition No. 4.—In lying-in hospitals where large numbers of patients are delivered under the same roof (if it exists) it *must* find its habitat; and we may add prove destructive in proportion.

Proposition No. 6.—It follows in steps of certain practitioners, whilst others are totally free from it in the same locality.

Proposition No. 7.—It is endemic, or confined to the locality where the contagion prevails.

Proposition No. 8.—It is not only confined to a given hospital, but is observed to haunt certain wards of that hospital in which it has its special habitat.

It is contagious consequently.

It is contagious consequently.

It is contagious consequently.

It is contagious consequently.

It is contagious consequently.

Proposition No. 9.—It occurs comparatively rarely among women confined in their own homes, where they are only exposed to the risk of self-contamination or other zymotic diseases which it is observed to succeed.

Proposition No. 10.—It is not observed to occur in small lying-in hospitals, or cottages where one or two patients cohabit, and the elements of its generation and spread don't exist.

Proposition No. 11.—We are causing the death by metria of a number of patients by continuing the gregarious system of large lying-in hospitals, who would escape under a system of segregation or isolation.

Proposition No. 12.—If lying-in hospitals are to be continued for the cure of patients and as schools of instruction, which they undoubtedly ought to be, they can only be so continued by substituting isolated cottages or pavilion hospitals with one or two beds in each isolated room.

Proposition No. 13.—With our present knowledge the conclusion is inevitable, that the mortality among parturient women would be greatly lessened by an alteration in construction and an arrangement of lying-in hospitals which would secure segregation and prevent congregation.

But, Sir, the contagionists must go much further. They must use their reason, their experience, and their common sense, in testing the value of any apparently adverse statistics, I mean statistics that appear at variance with the principles that apply in all other contagious diseases; and if they find that any collation or coaptation of figures eventuated in bringing out results at variance with reason, experience, and common sense, and with those laws that apply immutably in all diseases of the zymotic and contagious types, then they must "hold fast by sound words," and reject the figures as either exceptions which prove the rule, the explanation of which they are ignorant, or fallacies beyond their detection. Such are the figures, from what quarter soever they may come, that would go to prove that contagious diseases will not spread, *ceteris paribus*, in a direct ratio to the number exposed to the contagious influence. This, supplementing the effect of crowded houses in producing disease, is, in fact, the gist of the whole question lying at the root of this discussion. If a disease be contagious it can only spread by exposing a susceptible party to the influence of the contagion. If two be exposed the risk is doubled; four, quadrupled; and so on in an arithmetical ratio. Exactly in the same ratio is the risk in the spread of metria in the larger in comparison to the smaller cottage hospitals, arguments, elaborate treatises, and statistics *notwithstanding*.

Most of my commentators have started on a wrong basis in this discussion.

They have dealt with me as an antagonist in a matter in which there can be, or at least there ought not to be, no antagonism.

We are here as a scientific body, discussing an abstract sanitary question.

I affirm that there is a preventable loss of human life from a particular disease.

I suggest the method of lowering this mortality, and how am I met?

By a denial that the mortality exists.

I go into my proofs, and my facts are not disproved.

But a standard of mortality is set up different from that selected by me.

The invariable rule hitherto with sanitarians, whose ostensible motive is to improve the death-rates, is to place the highest standard before them, and direct their efforts to accomplish this.

The rule adopted by my commentators has been to select the lowest standard, and to level down to this.

What should we think of the physicians of Newcastle-upon-Tyne if, in answer to Dr. Farr's strictures upon the unhealthiness of their town, and his remonstrances upon their high death-rate, 37 in 1,000, they, in place of directing their attention to ascertain the causes and removal of their unenviable notoriety, denied its existence, and then set to work to prove their case by a comparison with the mortality of Manchester, which is equally notorious? Not Hull, in which the mortality amounts to only 23 in 1,000.

Yet this is exactly what has been done by my commentators, who have questioned my statistics, and adduced counter statistics showing a higher death-rate in bar of correcting the unnecessary death-rate that I have pointed out. A large proportion of this debate has been directed to this futile, this irrelevant object. Our attention has been misdirected. The "*tu quoque*" is no justification. The "I am no worse than my neighbour" is no excuse.

A grievous mortality exists in these great hospitals. I care not *where else* it exists if I can prove to you that it does not exist *elsewhere*. If I can show you that human life is preserved in the proportion of 2 to 1 or 20 to 1 in a different place by a different plan from that adopted in the hospitals or places where the mortality exists; and that such a plan is available and practicable, or even not impossible in these also, my case is made. Now, Sir, I have proved all this, and nothing remains to my opponents but to withdraw an antagonism that has already, I regret to say it, attracted to this discussion an unenviable notoriety. I have proved, Sir, not only that the high rate of mortality from metria exists in our hospital, but that it has done so with little intermission from its foundation to the present day. What says a resolution of the governors on the subject, passed on the 17th June, 1815, fifty-three years ago:—"A crowded state of the wards appears to the committee rather incompatible with the health of the patients, as, under such circumstances, the hospital will thereby remain liable to a recurrence of *that infectious and fatal fever which has on several occasions been so severely felt.*"

(To be continued.)

Correspondence.

LARGE FAMILIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—That the results to which tend the marriage-bed ethics of your correspondent, "Prudentia," in your issue for October 6th, would, in many respects, be a great improvement on the haphazard animal way in which children, often in large numbers, are procreated in wedlock, will be disputed by few who approach the subject without prejudice. But the mere question of the advantages which arise from the number of children being somewhat in keeping with the financial means of the family, and the physical ability of the wife satisfactorily to bear and rear offspring, is not one that can occasion much discussion. The question which really affords room for divergence of opinion is the practical one as to the employment of means to secure this accordance. It is hardly possible to frame a satisfactory reply to the observations of "Prudentia,"

without being in possession of his views on the practical question.

There would seem to be only two ways of controlling the number of births in a family, these are:—1. Seclusion of the wife from the husband, so as to remove all chances of pregnancy, except when mutually agreed on. This would be simply impossible for the great mass of the people, owing to the confined character of their dwellings, and the nature of the only domestic arrangements in their power, even if it were by mutual consent determined on. In cases where it might be possible, it would, if effectually enforced, cause such prolonged seclusion as to be almost tantamount to permanent estrangement; for there is no direct relation between immoderate indulgence of the sexual appetite on the part of any one couple, and the procreation by them of many children. Indeed, there are reasons why a woman, married, for instance, to a sailor in the foreign trade, might be expected to bear more children than if she lived in constant cohabitation with her husband. 2. The adoption of some marriage-bed check to the results of cohabitation as usually carried on. This involves grave considerations of sentiment, morality, and health; but is, at least, possible for all classes, and, being so, whereas the other alternative is impossible for comparatively few, is really the matter into which the question of "large families" resolves itself.

Such being the case, it cannot be out of place, before going further, to stop and ask whether this is the subject which your correspondent intended to put forward for debate, and you would wish to be freely discussed in your columns. If so, there will probably not be wanting persons to go fully into it; but it ought, beforehand, to be distinctly understood that the real question is to be tackled, and not some false issue having only a covert bearing thereon.

Yours obediently,

J. D. M.

London.

THE PROPAGATION OF THE SPECIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The Duke of Argyll, in his work on Primeval Man, states on the authority of Mr. Stuart Poole, of the British Museum, that the beginning of the Egyptian monarchy under the Pharaohs, took place seven centuries before Abraham, or in the twenty-eighth century B.C. According to Ussher's interpretation of the Hebrew Pentateuch, this would be 400 years before the Flood; so that, if we are to believe both statements, it is evident the Flood could only have devastated a small portion even of the inhabited world. The point, however, to which I would draw attention is, that his Grace, finding that according to the computation of the Septuagint, the Flood took place more than eight centuries earlier, or 450 years before the above-mentioned accession of the Pharaohs, doubts yet whether such period of time would suffice for the propagation of the human species, from the small number who left the ark, to the immense multitudes necessarily supposed in the formation of great monarchies (vide pp. 83—89).

A little consideration will show that there is no impossibility in the matter. We must remember that the eight persons mentioned in Scripture as surviving the Deluge were in an advanced stage of civilisation, and, therefore, would be able to protect themselves and their children from the hardships of savage life, and propagate much faster in consequence. In fact, they were *colonists*, who had crossed the waters from the old world to the new, and who had settled down, furnished with various implements for the tillage of the soil, and for the construction of dwellings substantial as the ark, and having, also, their several beasts of burden ready to hand. They might have considerable difficulty in obtaining a continuous supply of food; but this would be no obstacle in the way of their speedy multiplication, for, as we are all well aware, poverty and propagation are strangely allied. And to show with what wonderful rapidity the human race actually can multiply under, apparently, the most disadvantageous circumstances, I need only refer to the case of the Israelites during their residence in Egypt. The best commentators consider the 430 years of Israel's sojourn (mentioned in Exodus xii. 40) as extending from Abraham's entry into Canaan (Gen. xiii.), when God showed him the land which his seed should possess; that is, they place the exodus from Egypt in the year B. C. 1491, and the visit of Abraham to the promised land in the year B. C. 1920. If this be correct, Jacob's descent into Egypt took place about the year B. C. 1706; and it follows, that only 215 years

elapsed before the *seventy* persons, who then composed the chosen flock, became the immense army of "*six hundred thousand men, beside children,*" which marched into the wilderness (Exod. xii. 37); and even from the date of the Patriarch's marriage to Leah and Rachel (b.c. 1760), which brings us to the very point at which the family, destined to be a nation, began to enlarge its circle, there would elapse not more than 270 years, before the progeny of one man became the mighty host above mentioned; in the book of Numbers (chap. i.), we are informed that this immense number, which is specified more particularly as 603,550, consisted solely of "*men of twenty years old and upward who were able to go forth to war,*" and did not include either the women or children, or even the tribe of Levi. Thus, in about 240 years (giving thirty years for the sons of Jacob to arrive at maturity), each of the twelve parent stocks would have branched out and increased to an average tribe of 50,000 fighting men: Judah, indeed, numbered 74,600 (Numb. i. 27). In another 240 years, if each of those 50,000 had founded a family of like size, each tribe would more than have doubled the present population of the globe.

But it may reasonably be objected that the children of Israel at this time were extraordinarily prolific (Exod. i. 7, 9, 12). Therefore, we will proceed with our calculations upon a somewhat lower rate of increase. Beginning with the *three* rising families that left the ark, we will suppose that each pair produced on the average *six children*, and that in succession the new families were completed before the parents had exceeded, on the average, the age of *thirty years*, all of which I imagine, is fairly within the bounds of possibility. We may, then, suppose that the female portion of the population did not outnumber the male, though, where plurality of wives is general, there, of course, propagation is more rapid; nay, we may even suppose that the parents constantly dropped into their graves as soon as their families were completed; yet shall we arrive at very surprising results, for we shall find that at the end of 450 years, this little flock must have numbered, at least, *eighty-five millions*! sufficient these, surely, to form several considerable monarchies, especially such monarchies as that of Egypt, of which the Pharaoh who reigned when Moses was born, said that it was even then outnumbered by the Israelites (Exod. i. 9).

To explain—the population would treble itself every thirty years, thus:—

Anno Diluvii.	Population.
0	6 Shem, Ham, Japheth, and wives.
30	18
60	54
90	162
120	486
150	1,458
180	4,374
210	13,052
240	39,156
270	117,468
300	352,404
330	1,057,212
360	3,171,636
390	9,514,908
420	28,544,724
450	85,634,172

This supposes, as I have said, that the new families were completed before the parents were, on the average, more than thirty years of age. But there is nothing *impossible* in such a supposition; and since the average age of death is allowed to be equally low, it must be admitted that we certainly do not unduly strain the figures.

Trusting that you will kindly insert this in your valuable journal,

I have the honour, sir, to remain,

Your obedient servant,

DANIEL BIDDLE, Surgeon, &c.

Kingston-on-Thames: Sept. 25, 1869.

Medical News.

A QUARANTINE BOARD has been appointed in Jamaica, consisting of Deputy Inspector-General Dr. James Fraser, C.B.; Deputy Inspector-General Dr. James Donnet; Dr. William

Steventon, Medical Superintendent of the Public Hospital; Dr. Charles Campbell; and Major Prenderville, Inspector-General of Constabulary.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—At a meeting of the Royal College of Surgeons of Edinburgh, on the 20th inst., the following office-bearers were elected for the ensuing year:—

President: James D. Gillespie, M.D.

Treasurer: John Gairdner, M.D.

Librarian: Archibald Inglis, M.D.

Secretary: James Simson, M.D.

President's Council: James S. Coombe, M.D.; Andrew Wood, M.D.; James Dunsmore, M.D.; James Spence, James A. Hunter, M.D.; Henry D. Littlejohn, M.D.; John Gairdner, M.D. (ex officio).

Examiners: W. Dumbreck, M.D.; A. Inglis, M.D.; R. Ormond, M.D.; J. Dunsmore, M.D.; P. D. Handyside, M.D.; J. D. Gillespie, M.D.; H. D. Littlejohn, M.D.; Patrick H. Watson, M.D.; D. Wilson, M.D.; J. Smith, M.D.; D. M. C. L. Argyll-Robertson, M.D.; J. Bell, M.D.

Assessors to Examiners: J. S. Coombe, M.D.; W. Brown, A. Hunter, M.D.; J. Spence.

Officer: J. Dickie.

OPIMUM IN CHINA.—It appears from this year's consular reports from China that the consumption of opium in that empire is increasing, and that there is an increased growth of opium in China itself. Early in the year an Imperial decree was issued strictly prohibiting the cultivation of the poppy plant in the Chinese empire, and alleging that there would be danger of its interfering with the growth of food, and causing a scarcity of the means of subsistence; the apprehension of loss of tariff duty by a lessened importation of Indian opium may, perhaps, have been an influential reason for the decree. It threatens offenders with merited punishment, but attaches no specific penalty to disobedience; and it is thought that this decree will have no more effect than that of 1865 to the same purport, and that it will most likely be chiefly used by officials as an occasion for extorting money from the pockets of producers. There is evidence of extensive poppy cultivation in several parts of China. It has spread rapidly within the last few years in the vast region of Eastern Mongolia and Northern Manchuria, and is thence brought down to the coast, competing with Indian opium in the Newchwang market. Opium is grown also in several southern provinces. It has been grown for years in the extreme south-west, in the province of Yunnan, the larger proportion of which has thrown off its allegiance, and is now practically an independent kingdom, governed by a Mahomedan, named Tu Wen-hsin, said to be styled by his subjects the "Hsi-Mi-Kuo-Wang," or "King of the Consolidated West," and who has established his Court at Tai-li-fu, not far from the frontier of Burmah, called by the Chinese "Mien-tien." Mr. Mongan, the British Consul at Tien-tsin, states that opium is brought into that port either crude or prepared. In the former state it is generally spoken of as "tu," earth, or clay, from its resemblance to lumps or cakes of common clay; and the native, as distinguished from the foreign, which is termed "yang-tu," or foreign earth, is called "hsi-tu," or western earth, a name which seems to have a geographical reference to producing provinces. Prepared opium, called "ya-pieu-kao," is at Tien-tsin generally composed of foreign and native drug boiled down, and often largely adulterated with glutinous substances, such as a decoction of the berries of a leguminous tree called the "huai-shu," which grows abundantly in that part of the country. In quality some of the Chinese opium is not much below Malwa; but it is inferior in strength and flavour, and smokers prefer the Indian drug, although its price may be double that of the native; and, in fact, the latter is chiefly used for mixing with the former, seven-tenths foreign to three-tenths native.

NOTICES TO CORRESPONDENTS.

ELGINENSIS.—Your signature was accidentally omitted by the printer in the article inserted in our last, headed "Large Families: Prudentia and the *Elyan Courier*."

S. U. U.—The article to which you draw attention is beneath notice. ERRATUM.—"LARGE FAMILIES."—In the letter published on the 6th October, signed "Prudentia," for "large families are especially blameable," &c., read, "a large family is especially," &c.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In reply to your correspondent's inquiry as to where he will find Dr. Mulvaney's treatise on the "Rational Treatment of Consumption," I beg to inform him that it commenced in No. 18, Vol. V., of your Journal, that for 29th April, 1868.

Will you, or some of your readers, kindly inform me where I can procure an apparatus for making oxygen for inhalation, and the cost.

I am, Sir, yours, &c.

Cappoquin.

F. M. LUTHER, M.D.

THE INTERNATIONAL MEDICAL CONGRESS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Your Journal for October 13th contains the following:—"Dr. Routh sent a communication upon the mortality amongst children, &c." Permit me to state that your Special Commissioner was somewhat in error, the title of my paper being, "On the Causes of the great Mortality amongst Children, especially in the Manufacturing Towns, and on the Means of Diminishing them." Further, that its author is not Dr. Routh, but your obedient servant,
 Dr. Romm.
 London.

VACCINE FROM THE HEIFER.

In reply to the inquiries of many of our readers relative to the article which appeared in this Journal for October 6th, on Dr. Blanc's system of "Vaccination Direct from the Heifer," we have received the following letter from Dr. Blanc, who is now on his way to India:—

Southampton, 19th October.

Sir,—I beg to acknowledge the receipt of your memorandum, and to return my best thanks for your able article.

I have given up *animal vaccination in London*. My experiments were entirely in a scientific point of view, and, having succeeded in what I had desired, I now leave the work to others.

I am leaving on Friday for Bombay. Should I be so stationed 'as to be able to receive English newspapers, I will certainly become a subscriber to the MEDICAL PRESS AND CIRCULAR—a periodical I have always greatly admired.

I remain, faithfully yours,
 H. BLANC.

BOOKS, PAMPHLETS, &c., RECEIVED.

- Infant Life: its Nurture and Care. By C. N. G. With Preface by Erasmus Wilson, F.R.S. London: Sampson and Low.
- A Manual of Surgical Operations. Second Edition. By Joseph Bell, F.R.C.S. Edinburgh: Maclachlan and Stewart.
- A Guide to the Examination of the Urine. By Dr. Wickham Legg. London: H. K. Lewis.
- A Vindication of the Medical Council. By Andrew Wood, M.D. On the Presence of Sulphocyanides in the Blood and Urine. By Arthur Leared, M.D.
- Remarks on the Training of Nurses. By Dr. S. D. Cross. Philadelphia.
- Novus Theretetus. By W. H. Stone, F.R.C.P. London: John Churchill and Sons.
- Hospitalism and Zymotic Diseases. By Evory Kennedy, M.D., &c. London: Longmans, Green, and Co.
- The New York Medical Journal. Boston Medical Journal. The New Orleans Journal of Medicine.

Deaths.

- ADAMSON.—On the 11th inst., Dr. W. Adamson, of Marnoch, Banff shire, aged 75.
- BELL.—At Peshawar, India, Arthur Bell, M.R.C.S.E., Surgeon 36th Regt., aged 41.
- CHEEK.—On the 16th inst., at The Grove, Upper Norwood, G. N. Cheek, M.R.C.S.E., Surgeon Bengal Service, aged 37.
- HUMPHRIES.—On the 9th of July, at Taranaki, New Zealand, E. L. Humphries, M.R.C.S.E., formerly of the Kingsland road, aged 53.
- M'KINNEL.—On the 9th inst., at M'Murdostown, Dumfriesshire, John M'Kinnel, M.D., late Assistant-Surgeon H.M.'s 73rd Regiment.
- ROPES.—On the 15th ult., at Boston, U.S., Francis C. Ropes, M.D.
- SWENY.—On the 4th inst., Mark Sweny, L.A.H. Dub., of Lincoln place, Merrion square, Dublin, aged 53.
- VINALL.—On the 16th inst., at Chelsea, Charles Vinall, M.D., late of Birling, Kent, aged 73.

FILMER'S

EASY CHAIRS, COUCHES, AND SOFAS,

THE BEST MADE.

300 different shapes constantly on view for selection and immediate delivery. Easy Chairs made to any shape on approval.

FILMER & SON,
 UPHOLSTERERS,

31 and 32, Berners street, Oxford street, W.;
 Factory, 34 and 35, Charles street.

Section showing the actual size.

Range 90° to 110°. (Vide the *Lancet*, July 3rd, 1869.)

IMPROVED CLINICAL THERMOMETERS,

Possessing the following advantages:—

- Absolute accuracy.
- More extended range.
- Increased sensitiveness.
- Non-liability to derangement.
- Self-registering.
- Great portability.

By a new method of dividing the scale, the one-fifths of degrees may be read with equal facility to the degrees. Price, in case, 10s. 6d.; or packed safely and sent free by post, 1s. extra. Descriptive Circular post free on application.

T. HAWKSLEY, Surgical Instrument Maker, 4 Blenheim street, New Bond street, W. P.O.O. payable Vere street, Oxford street.

GLENFIELD STARCH.

EXCLUSIVELY USED IN THE ROYAL LAUNDRY.

And Her Majesty's Laundress says that it is THE FINEST STARCH SHE EVER USED. Awarded PRIZE MEDAL for its Superiority.

WHEN YOU ASK FOR

GLENFIELD STARCH,

See that you get it, as inferior kinds are often substituted. WOTHERSPOON and CO., Glasgow and London.

SAUCE.—LEA & PERRINS.—SAUCE

THE "WORCESTERSHIRE,"

Pronounced by Connoisseurs

"THE ONLY GOOD SAUCE."

Its use improves appetite and digestion.

UNRIVALLED FOR Piquancy and Flavour.

BEWARE OF IMITATIONS

To avoid which, see the Names,

LEA & PERRINS, on all bottles and labels,

Ask for "LEA & PERRINS" SAUCE.

Agents—CROSSE & BLACKWELL, London, and sold by all Dealers in Sauces throughout the World.

FIELD'S "TRANSPARENT HONEY" SOAP

in tablets, 5 to 10, beautifully scented, and "YORK AND LANCASTER" Tablets. Exquisite rose perfume. Both the above packed in handsome boxes of 3 Tablets each, 1s. per box.

Wholesale—J. C. & J. FIELD, 36 UPPER MARSH, LAMBETH, S.E.

FIELD'S "UNITED KINGDOM" SOAP.

(Registered.)

This beautiful soap is made in six varieties, White and Brown Windsor, Honey and Glycerine, &c., each tablet having a distinctive tint and perfume, the whole forming a combination of colour, form, and fragrance entirely unique. Price 3d. per tablet.

See the name on each. Wholesale of

J. C. & J. FIELD, 36 UPPER MARSH, LAMBETH.

DIABETES.

BONTHON'S DIABETIC BREAD AND BISCUITS

Have been approved by the Profession and by Diabetic Patients; contain no starchy matter, and are highly palatable and agreeable.

Country Orders punctually attended to.

Address, J. BONTHON, 106, Regent-street, London, W.

MANUFACTURERS

TO THE QUEEN.

ONLY PRIZE MEDALS.

LONDON, '62; DUBLIN, '65.

ONLY SILVER MEDAL,

PARIS, 1867.

"Purity and Excellence of Quality."

THEIR GENUINE AND DOUBLE SUPERFINE ARE THE QUALITIES PARTICULARLY RECOMMENDED FOR FAMILY USE.

EXPERIENCES OF A REGIMENTAL SURGEON IN INDIA.

By C. A. GORDON, M.D., C.B.,
Deputy Inspector-General of Hospitals.

(Continued from page 244.)

PARALYTIC AFFECTIONS.

ACCORDING to regimental statistics it would seem that paralytic affections are less common among soldiers in India than in that portion of our army stationed in the United Kingdom, a circumstance in some measure to be accounted for by the fact that diseases implicating the cerebro-spinal system in that country usually occur with such severity as to destroy life before the lesions upon which paralysis directly depends have had time to occur. Thus, no more than 28 cases among soldiers, and 2 in officers, are borne on the records of the 10th Foot throughout thirteen years' service on the Bengal side, none appearing to have occurred either among the wives or children of soldiers; although the same documents show the prevalence and mortality of the entire class of diseases affecting the nervous system to have been 288 cases, of which 53 were fatal among men; 16, and 3 fatal, among officers; 19, and 2 deaths, among women; 31, and 18 deaths, among children. Among the two latter classes of persons no case of paralysis in any form seems to have happened. Information is unfortunately wanting as to the precise nature of the affection in the case of the officers whose deaths occurred from this cause; but the soldier who died paralytic was a man who had, for a considerable time, suffered from secondary syphilis, on which lesion of the spinal cord doubtless depended. He gradually lost the power of motion in the lower extremities, and finally sank under diarrhoea and bed-sores.

It is not to be supposed, however, that because the rate of mortality by these affections was so small as is here

represented, persons once their subjects returned after a time to their duty. Such was by no means the case. On the contrary, it does not appear that any instances of recovery really took place, although I do not see why, in some instances, at any rate, of local paralysis, as of the wrist or eyelid, the proper functions of the parts may not be restored. In cases of paraplegia or hemiplegia, especially if occurring as independent affections, although medical treatment may produce some degree of benefit, it is hopeless to look for recovery in India. The subjects should, in all cases, be despatched to England by the first favourable opportunity.

The particular influences upon which paralysis in some cases depends, or, in other words, its *exciting causes*, are in many cases obscure; so much so, that cases of the affection implicating entire limbs, or isolated portions of them, are often referred, by natives and Europeans long resident in the country, to the mere passage of currents of hot air across them. The effect of direct solar heat upon the head or loins is more apparent, and we observe attacks of the affection following upon partial seizures of heat apoplexy. Nor is it alone in man that this is believed to occur. Horses are said to be particularly prone to partial paralysis of the hinder extremities from the effect of solar heat upon the spinal marrow, to prevent which it is customary to protect their loins by heavy folds of cloth while picketed, as they usually are. Perhaps a similar belief, whether formed with or without reason, has led to the employment by natives of the waist cloth, or *cummerbund*—an article of dress found by several of us to have afforded great comfort during the exposure to which we were subjected in the Indian mutiny.

It has been asserted that, by a careful observation of the conditions attending paralysis of the lower extremities, the nature and seat of the lesion to which they owe their origin may be ascertained. For example, if in the application of an irritant to the foot, involuntary contraction of the limb take place, the lesion may be considered to exist in the upper part of the cord; if they are not exerted, then it either is confined to, or has descended to, the lower portion of the cord. Then, again, as to the conditions

upon which paralysis depends, the following rules have been laid down*—namely:—

1. If incomplete and with spasms, it probably arises from meningitis, cerebral or spinal.

2. If gradual and with contraction of the flexors, from cerebral or spinal softening of inflammatory nature.

3. If gradual and without contraction of the flexors, from non-inflammatory cerebral or spinal softening.

4. If sudden and again suddenly disappearing, from temporary congestion.

5. If persistent and with epileptic symptoms, from hæmorrhage.

How far these arbitrary rules are trustworthy I have not personally tested; nevertheless, as they are deserving of notice I give them here for the benefit of medical officers in India.

Shaking Palsy, or paralysis agitans, is seldom met with among soldiers, probably for this reason, that this form is chiefly a disease of the more advanced in life. All the cases of this form which came under observation in India occurred in men of long service in that country, and were addicted either to spirit drinking or to opium eating. In none of them, however, was the attack of a nature to require their admission into hospital, although in all it disqualified them for further duty. And having alluded to the vice of opium-eating, I would observe that it is, in all probability, less prevalent among our soldiers in India than it was in former years. Even so lately as 1854 there were in the 10th Foot several old soldiers who were habitual opium-eaters, and there was every reason to believe that the vice was no less prevalent in other regiments. The system of "relief" of regiments now in force renders the style of persons formerly known as the "old Indian soldier" an institution of the past, and at the same time probably effects considerable changes in the habits of the men; yet that there are still some who indulge in the use of opium, not only in India, but for some time after their return to the United Kingdom, I have ascertained, and been further informed of the ingenuity practised by them in the manner in which they smuggle the drug into England, by having their boots provided with false soles before leaving India, and filling the intervening space with the narcotic.

Local Palsy.—Of the various kinds of local paralysis, those most commonly met with in India among soldiers are paralysis of one side of the face, ptosis, and wrist-drop. This form may even be confined to a finger or a phalanx, and in all cases is generally attributed to the effects of "a stroke of the wind," or, in other words, its precise cause is obscure. In addition to the above forms of paralysis, it is by no means unfrequent in India to meet with instances in which a person recovering from severe malarious fever, finds that one or more of his limbs are attacked with this form of disease, sensation being in some cases unaffected, in others impaired, in others increased; while, in other instances, the sensation of different sides of the body is deranged in such a manner, that, for example, water being applied gives a sensation of heat to one and cold to another limb. The disease in these cases has been referred respectively to the presence of inflammatory action in the nervous centres, to what has been termed "impaired nervous power," and to the poisonous effects of malaria in the system. In all such cases recovery is slow. The patient must in all cases proceed to a temperate climate, where, under suitable regimen, recovery after some years may be complete, although the instances are by no means rare in which the subjects of the disease never fully recover the full power of the affected part.

Epilepsy.—This disease, like the class of affections last described, would appear to occur less frequently among soldiers in India than in those stationed in the United Kingdom. Probably one cause of this difference exists in the circumstance that the disease, being one chiefly of early manhood, recruits are rejected when suspected to be,

or are actually suffering from it, so that they do not reach the country; yet that another cause for the comparative exemption probably exists seems to be indicated by the fact that, according to regimental statistics, no case of the affection is recorded among the children during thirteen years' service of the corps in different parts of India. The children of soldiers there are, as a rule, better fed, and possibly better taken care of in other ways than are those of the poorer classes in Britain; and this circumstance may also diminish their liability to epilepsy. Yet there is another and probably a more constant cause of the difference than either of these, namely, the probability that children who have an existing tendency to cerebral disease, like "those whom the gods love, die young." Acute hydrocephalus, or convulsions, destroy them before they have reached the age when epilepsy usually supervenes.

The affection seems also to be of comparatively rare occurrence among soldiers' wives and among officers, and when happening among soldiers themselves seldom destroys life, although it unfits a man for continuing in the army, when occurring as an idiopathic affection. Cases do occur, although not frequently, in which an apparently pure attack of the disease follows upon a debauch, or is directly traceable to the irritation caused by intestinal worms, especially the long worm and the ascarides. These cases, however, are, for the most part, readily distinguished. Among other causes which induce the disease in India, local injuries are not unfrequent, while cases of the affection are by no means rare in persons who have undergone a severe attack of "jungle" or marsh remittent fever, or have been subjects of sunstroke.

(To be continued.)

Hospital Reports.

UNIVERSITY COLLEGE HOSPITAL.

LAST Wednesday Mr. Erichsen operated at University College Hospital for an aneurism, situated partly below and partly above Poupart's ligament, by tying the left iliac artery near to its junction with the common iliac. The patient's limb was then swathed in cotton wool and bandaged from the foot upwards. Mr. Erichsen said he thought there was every hope that the case would do well. He mentioned, too, that there happened to be in the wards at present another case of aneurism in the popliteal space, in which compression had as yet failed to effect coagulation, although it had been methodically kept up for nineteen days. It was possible that it might be necessary to have recourse to ligature.

ROYAL LONDON OPHTHALMIC HOSPITAL.

At the London Ophthalmic Hospital, Moorfields, on Friday last, we saw the following operations:—

CASE 1. Mr. Lawson performed excision of the cornea in a boy of about ten years of age, who was suffering from staphyloma, as follows:—Three needles, armed with ligatures, were passed through the margin of the sclerotic from side to side, and the cornea having been excised, the needles were pushed completely through, and the threads tied, closing up the wound in the sclerotic. The object of this process, due, we believe, to Mr. Critchett, is to prevent, firstly, the escape of the vitreous; and, secondly, to render the passage of the needles more facile, whilst the eyeball is plump. The patient was under chloroform.

CASE 2. An infant, with double congenital cataract, was operated on by Mr. Soelberg Wells. The cataracts were both broken up by the needle introduced at the margin of the cornea. The child took chloroform.

CASE 3. This was a case of double divergent strabismus in a young woman apparently about the age of twenty. Mr. Wells operated on one eye only, the right eye, observing that it was dangerous to operate on both in cases of

* See Wood's "Practice of Medicine," p. 362, Vol. II.

divergent squint, since this might result in a worse condition than before. The incision was, as usual, made beneath the conjunctiva.

ROYAL VICTORIA HOSPITAL, NETLEY.

(Continued.)

PROFESSOR Maclean's cases include four very interesting ones of abscess of the liver:—

I.—Case of Abscess of the Liver evacuated by Bowditch's Syringe; Rapid Recovery.

The first illustrates the method of evacuating abscesses of the liver without the admission of air, and its successful result will encourage Medical Officers serving in India to give a fair trial to so promising an operation.

Private Johnson, age twenty-eight, six years of India, and eighteen months of home service. Suffered in India from occasional attacks of ague and diarrhoea, but on the whole had fair health. Embarked at Bombay with his regiment for service in Abyssinia. Contracted dysentery immediately on landing, which he attributed to bad water. Improved under treatment: but as he was thought unfit for active service, was invalided home. At Suez, *en route* for England, he was seized with the first symptoms of hepatitis. These appear to have been well marked. On admission at Netley he was in a condition of great debility and depression; much emaciated; appetite bad; temp. 101.1; pulse, 83; respiration, 27.

On examination, the liver was found much enlarged, stretching four inches and a half below the false ribs, and upwards to the intercostal space between fourth and fifth ribs. A tumour, globular in shape and fluctuating, could be plainly seen and felt, proceeding from under the false ribs in the right hypochondrium, plainly hepatic.

On the 17th April I drew off 16 oz. of "laudable" pus, using Bowditch's syringe, carefully excluding the external air. Immediate relief was experienced, pulse and temperature quickly fell to the natural standard, the patient soon regained flesh, and was discharged in excellent health.

Dr. Maclean adds that, "from the day the operation was performed he may be said never to have had a bad symptom. The puncture was so small that in a few days its exact position could not be distinguished. In this case there was a distinct history of previous dysentery, from which in a chronic form, he was still suffering on admission. Yet, as the abscess was clearly single, it is not probable that it had a pyæmic origin. The rapidity with which the constitutional symptoms subsided after the operation was very striking."

II.—Abscess of Liver, discharging through Right Lung: Inhalation of Carbolic Acid Vapour.

Corporal Thomas Smith, 4th Regiment; age forty-four; fourteen years' service. At all and powerful man; served in India from 1857 to 1867. With the exception of slight attacks of intermittent fever, had good health until 1867, when he had an attack of dysentery, from which he was suffering when he sailed with his regiment for Abyssinia. Unlike others in the same state, he recovered from his complaint at Annesley Bay, and marched with his regiment to Magdala and back. At the close of the campaign, his regiment returned home, but he, having volunteered into another regiment, returned to India. In Abyssinia he was exposed to heat by day, and cold and sometimes wet at night, and underwent much fatigue.

On the return voyage to India he suffered from pain in his right side, not, however, of a very severe kind.

In June 1868, the pain became sharper, and attended with cough; soon followed by profuse expectoration of purulent matter, mixed with blood. The pain then ceased. "When the expectoration was free there was no pain, but when it ceased, pain returned." He was invalided, and arrived at Netley on the 17th December, 1868.

On admission he was somewhat anæmic, but not emaciated, and his general health was good; hepatic dulness extended to within half an inch of the right nipple, and the respiratory sounds at the base of the lung were feeble and indistinct,—normal in other parts of the chest. The expectoration amounted to about 14 oz. daily of mucopurulent and bloody fluid. He was placed on a liberal diet, with wine and porter. On several occasions the expectoration almost ceased, but, as before, this was always attended with a return of pain, which was removed when, under the influence of fomentations,—the inhalation of steam, or steam and turpentine,—the discharge returned.

Finding the case was making little satisfactory progress, one part of carbolic acid to 100 of water was introduced into Adams' inhaler, and the vapour breathed. This was continued for a week, and at the end of that time the expectoration was diminished, and the cough much relieved, and the patient's general health much improved.

The quantity of acid was increased gradually from three to seven drops. The expectoration is now reduced to less than an ounce daily, and is gradually becoming less. The patient always expressed himself relieved by the use of the carbolic acid inhalation, and is confident that it checked the expectoration. He has improved in appearance; is gaining flesh and colour; his appetite is good; his pulse and respiration normal. The expectoration is now much less purulent than it was, although still presenting the dark red colour which it did from the beginning.

There was a distinct dysenteric history in this case, and it is possible that more than one abscess may have formed on the convex aspect of the gland, and coalesced, having one communication with the lung.

The carbolic acid inhalations appear to have done good, and are worthy of further trial in similar protracted cases.

III.—Abscess of the Liver discharging externally; Carbolic Acid Injection.

Private W. Northcott, Royal Artillery, age thirty-two; two years' home and eleven years foreign service. Health previous to embarking for service in India, good. Arrived in Madras in 1857, where he served for three months, and had a few slight attacks of ague. Was sent to Bengal, and served in Central India during the Mutiny. Had several attacks of intermittent fever. In June 1860, served in Sir Hope Grant's campaign in the north of China. While on active service his health was good. At the close of the war was quartered at Shanghai, where he had a sun-stroke, and suffered from diarrhoea. In 1865, he returned to India, and served in Bombay, Kirkee, Sholapore, Hyderabad (in Scinde), and, with the exception of a few attacks of ague, had fair health. Embarked for Abyssinia in November 1867; when he had advanced about 200 miles towards Magdala, exposed to a high temperature by day and cold by night, he was seized with acute pain in his right side. After treatment, the disease appears to have passed into a chronic form, and he was sent home. During the voyage an abscess in the liver was diagnosed, which pointed externally, and opened by several small apertures, three inches below the false ribs, and to the right of the mesial line, and discharged gradually a considerable quantity of dark red purulent matter. After a time the openings coalesced, and continued discharging from three to four ounces daily. On admission, the liver extended upwards to the upper margin of the fifth rib, and downwards to within half an inch of the umbilicus. The edges of the opening present the puckered and depressed appearance usually seen in such cases. The patient was somewhat anæmic, but his general health, notwithstanding the discharge, was pretty good. Treatment at Netley consisted in attention to his general health, the use of tonics, a generous diet, and a fair allowance of wine. The amount of discharge varied: at times it would nearly cease, then some pain and

uneasiness would follow, requiring fomentation and poultices, followed by free discharge, and relief from uneasy sensations.

Finding that the patient's health was giving way under this protracted discharge, carbolic acid in the proportion of one part to 200 of water was injected, and the small orifice was dressed according to Mr. Lister's method. This treatment certainly had the effect of diminishing the discharge, which, before it was used, sometimes amounted to five or six ounces daily. Still, up to this time, April 29th, it has not ceased entirely, although it is diminished to less than a teaspoonful daily, having been going on more or less since the 26th of August, 1868, upwards of seven months. It is probable that in this case the cavity of the abscess is lined with a membrane which furnishes the discharge. No trace of hepatic tissue is now visible under the microscope.

Dr. Maclean remarks here:—"This case contrasts with that of Johnson's (*supra*), and illustrates the difference between the progress of a case where air has had free access to the cavity of an abscess, and one where air has been excluded. In the one case, although the patient had by no means so good a constitution, had been much pulled down by dysentery, and was altogether a more unfavourable subject, rapid, almost immediate, recovery followed the evacuation of the abscess. In the other, where air was unavoidably admitted, recovery, not yet complete, has been remarkably slow.

"Carbolic acid in this case had not a fair trial; I had no opportunity of using it until free communication with the external air had long existed. Yet it did good, and certainly appeared to diminish the quantity of the discharge.

"Where Bowditch's syringe is not at hand, it is certainly to be desired that Professor Lister's antiseptic dressing should have a fair trial in cases of abscess of the liver having an external opening. Professor Gairdner, of Glasgow, was good enough to send me notes of an interesting case of hepatic abscess occurring in the Glasgow Infirmary, which was successfully treated by Mr. Lister's method."

(To be continued.)

SPECIAL REPORT ON STUDENTS' TEXT BOOKS.

(Prepared expressly for the MEDICAL PRESS AND CIRCULAR,
by Professors in Schools of Medicine.)

No. V.

THE "Dublin Dissector" has long been a most popular Manual. Of late years, it is true, it has been largely superseded in the English Schools by Ellis, Holden, Wilson, and Heath; but it maintains its position in Ireland, and is still used by London students. It is, undoubtedly, a work of great merit. Clearly if not elegantly written, it avoids the extremes of too much minuteness and too much brevity. The type, though small, is distinct. The size of the two volumes, into which it is now divided, is handy. Each volume, foolscap 8vo, is rather smaller than one of Churchill's Manuals, some of which, by the way, sometimes grow to an inconvenient stoutness. Hence they are very portable, and well adapted for the coat pocket. It may be doubted, however, whether the matter contained within them is judiciously distributed. If a Manual of Practical Anatomy is divided into two volumes, the arrangement of the contents should bear a strict re-

gard to the convenience of the student. It should be remembered that the human body is divided into parts, and that the whole of each part is taken by one or two students. All the organs and structures of a part should, consequently, be described in the same volume, and in the same division of that volume. This is not the case with the "Dublin Dissector:" the anatomy of the head and neck is given at the commencement of the first volume; but the brain and cerebral nerves, the contents of the orbit and the eye, the nose and the ear, are relegated to the second volume. It may be pleaded that these parts are special, and that the brain is dissected separately after being kept several weeks in spirit.† The orbit, however, is always dissected early, before the body is turned for the dissection of the muscles of the back, and before this is done the brain has to be removed by the student, who ought to notice during the operation the relations of its lobes and nerves to each other and to the bones. On reference to the Preface, we find that the arrangement followed was "adopted from a conviction of its being well suited to the improvement of the anatomical student; and subsequent experience has confirmed this impression." In our opinion, this arrangement has some advantages, but for a "System of Practical Anatomy it is not sufficiently systematic." A work of this kind would naturally open with a general introduction to the pursuit of practical anatomy. Following this, there might most advantageously be a chapter devoted to such an outline of the structure and arrangement of parts in the human body as would smooth the path of beginners to a surprising extent, and afford them an elementary knowledge which many of them so sadly lack, and the want of which becomes a serious hindrance to progress and cause of aversion to the study. Similarly, at the commencement of the description of each division of the body, a statement of the plan of procedure to be adopted might be prefixed, together with some additional information of a general character bearing specially upon that division. As it is, most of the manuals of dissection presuppose a very considerable amount of knowledge on the part of the student without informing him what he ought to be acquainted with before taking the scalpel. He has to plunge at once *in medias res*, and if he is not fortunate enough to secure the services of the demonstrator, he hacks his part to pieces indefinitely, or gives it up in disgust, or sells it at half price to some idler who wants the credit of having dissected without the work, or some economist who wants the maximum of subject at the minimum of price. We remember very well beginning to dissect with a leg—we beg pardon, we mean a lower extremity. We were totally ignorant, but we were told that we ought to begin, and to begin with the lower extremity, because it was so easy. We knew nothing of fascia or hernia, and we knew nothing of the origins of the nerves. The numerous layers of fascia, and the points connected with femoral hernia, and the constant talk about the nerves arising from the lumbar plexus, before we knew what or where it was, were overwhelming. We were provided with an Ellis—a sufficiently indigestible book in itself for a beginner; but of all the indigestible parts of that indigestible volume, commend us to the first twelve pages of the dissection of the lower extremity, devoted to surface markings, and fascia, and directions for dissection, and

* The Dublin Dissector, or System of Practical Anatomy. By Robert Harrison, M.D., M.R.I.A. Fifth Edition. Tenth Thousand. Faunin & Co., Dublin; Longmans & Co., London; MacLachlan & Co., Edinburgh.

† This spirit is sometimes diluted with water by the beadies who sell it to the students—*pecunie gratia*.

cutaneous nerves arising from the cords of the lumbar plexus.

We would not be unjust to Ellis; for any one who has a fair knowledge of his anatomy, and for the student who is working for the University of London, Ellis is by far the best dissecting Manual. He is very precise and systematic—qualities which are extremely valuable under such circumstances—and he gives so much information that it is quite sufficient to read by him alone in order to obtain Honours at the University. We think, however, that it is a mistake for a beginner to use the book, and that he would learn more by starting with Heath. Both Ellis and Heath have the merit of separating the remarks about the dissections from the rest of the text. Ellis does this by prefixing the word Dissection to the paragraphs relating to it. Heath, more effectually, by placing the passages in brackets, and distinguishing them further by closeness of the type. The "Dublin Dissector" pays no attention to this point, perhaps intentionally, for the purpose of making the student read through the whole of the descriptions; but we very much doubt whether such fusion would effect this object.

As an example of the kind of introduction required in Manuals of Dissection, we must point once more to Heath, who opens with a chapter containing useful information about instruments, and the course which the student should pursue while he is dissecting. If to this had been added another chapter, with a sketch of the organs and tissues of the body, we should consider the Manual a still greater boon to first-year students.

The arrangement adopted in the "Dublin Dissector" is as follows:—Vol. I. opens with the dissection of the external parts of the head and face. The muscles especially are fully described, and described together, a separate section being devoted to an outline of the vessels and nerves met with in the dissection of the muscles. There is also a good account of the structure and relations of the salivary glands. We notice that the *orbicularis oris* is stated to have no bony attachment. Holden, in his illustrated Manual, is quite silent on the subject, and, indeed, scarcely describes the muscle at all as it is ordinarily described; but he mentions in a note an occasional slip to the septum of the nose. Quain, Ellis, Gray, and Heath all describe part of the muscle as arising from the upper jaw-bone, near the incisor teeth; and the three first give it connections to the lower jaw-bone, near the canine teeth.

The neck, treated of in Chapter 2, is dealt with in a similar way to the head and face. First come the muscles, with incidental observations on the veins, nerves, and fasciæ, and a description of the triangles, the thyroid, submaxillary, and sublingual glands. Then follow, in order, sections devoted to the vessels and nerves of the neck, the mouth, pharynx and larynx and tongue generally; the dissection of the pharynx; the dissection of the palate and its muscles; the dissection of the larynx, and the dissection of the deep muscles at the front and side of the vertebral column in the neck, the *longus colli*, *recti*, and *scaleni*. The characteristic features of the descriptions may be said to be the reservation of a full account of the nerves and vessels for the second volume, as well as of the tongue, orbit, &c., and the care which is taken with the accounts of the actions of muscles and the uses of parts dissected. We know of no school treatise used by students in which these accounts are excelled, if, indeed, they are equalled in any. Take, for example, the paragraphs

describing respectively the action of the muscles of the face in the expression of the emotions and the movements of the lower jaw. All the important points are touched without prolixity or repetition. In the second volume, the chapter devoted to the contents of the orbits contains a very full and interesting examination of the actions of the *recti* and *obliqui*, much superior to the accounts given in other text books. Nor are these accounts rendered the less valuable by the introduction of remarks explanatory of the pathological changes to which the various organs and tissues are liable.

The brevity with which the vessels and nerves are treated in the first volume, if this brevity is intended to aid the beginner, is, in our opinion, altogether neutralized by the absence of such a general preliminary sketch as would render the notice of the vessels and nerves intelligible. When the student reads that the nerves he meets with are branches of the seventh and fifth pair, and that the fifth pair consists of three portions—the ophthalmic, superior maxillary, and inferior maxillary—he derives information from which he can only profit if he is previously aware, as he often is not, what is meant by a pair of nerves, why they are numbered, where they come from, and how they get where they are found. Would it not be very advantageous to impart such elementary knowledge at the beginning of a dissecting manual? A few pages to be read before the scalpel is handled would effect all that is needed. Many men get up their bones by rote, learning, like parrots, the vessels and nerves passing through the foramina in the skull, without the least definite ideas of where they come from or the business they have to be in such positions; and many begin dissecting without either knowing their bones even in the parrot fashion, or the rudiments of the human body. Ask most first-year students who are dissecting what the aorta is, or how many nerves come from the brain; will they be able to answer correctly? So that we maintain the necessity exists of imparting such matters at the very outset of the book of the description before us. Too much of this kind is taken for granted, both in lectures and in books.

Chapter 3 treats of the thorax, beginning with the muscles outside and the axilla, and proceeding to the cavity. The muscles of the back occupy Chapter 4, which is very short. Chapter 5 gives the upper extremity. Chapter 6, the abdomen and pelvis. Chapter 7, the female organs of generation, with pathological observations. Chapter 8, the inferior extremities.

Vol. II. contains consecutively:—

Part II., the anatomy of the vascular system—viz., arteries, veins, and absorbents.

Part III., the anatomy of the nervous system, including the dissection of the brain, medulla, and nerves, and the anatomy of the organs of sense, skin, nose, tongue, eye, and ear.

Part IV., the anatomy of the bones and joints.

Lastly, there is an Appendix, with sections on the injection of arteries, and the mode of making dry preparations; on Laennec's division of the thorax; and on directions for opening the cranium, thorax, and abdomen. We offer a few additional remarks on parts which have attracted our attention.

The *rectus capitis anticus major* (p. 72) is described as arising from the four last cervical vertebrae, instead of with the anterior scalenes from the third, fourth, fifth, and sixth.

The point is of small importance; but the account differs from other authorities.

Both the internal and external intercostal muscles are said to raise the ribs and evert their lower edges. We had fondly believed that the actions of these muscles had been settled on mechanical principles by Dr. Hutchinson; but this statement, combined with recent theories, has again unsettled us. We are still very much inclined to pin our faith to Dr. Hutchinson, a very clear exposition of whose views may be found in Humphry "On the Human Skeleton."

The chapter on the thorax is very good. The heart, especially, is described at great length, physiology and pathology being liberally added to the anatomy. In the account of the muscular fibres of the heart, we do not notice any allusion to the arrangement made out by Pettigrew.

Since Mr. John Wood's article in the *Journal of Anatomy and Physiology* for 1868, and his lectures at King's College for some years, it has become necessary to revise the generally received descriptions of the limits of the trachea and arch of the aorta, with reference to the vertebræ. Heath, a pupil and colleague of Mr. Wood's in the King's College Dissecting-room, has been "faithful among the faithless." He has extended the trachea and the arch of the aorta to the sixth dorsal vertebra; and it appears that both Mr. Wood and Mr. Heath are borne out by the dead subject, and supported by the celebrated Russian surgeon and anatomist, Nicalao Pirigóff. Mr. Harrison is still in "the bond of iniquity," and gives the trachea the old limit of the third dorsal; but he has saved his credit with the aorta, for he judiciously observes that the arch of the aorta, though *not very accurately defined*, may be considered as extending from the left ventricle to the *fourth* dorsal vertebra, and abstains altogether from fixing limits to the separate parts of the arch.

Why is the endocardium called the endocarde?

The pericardium is not called the pericarde.

This nomenclature is not peculiar to Dublin, as Ledwich uses the ordinary Latin word endocardium.

Some useful hints to operators are contained in the section given to the anatomy of the abdominal wall and hernia, a part of the work which we regret not to be able to examine more at length.

The section on the uterus, and those on the brain and cord, in the second volume, contain physiological and pathological remarks. Ward concludes his excellent Manual on the bones by saying that anatomical description and physiological explanation should always go side by side; and the "Dublin Dissector" certainly endeavours exemplify this axiom.

There is little to be said about the accounts of the arteries and nerves; there is no special feature in them. The work concludes with chapters on the bones and ligaments. Both are well, accurately, and tersely given.

The book is well illustrated with plates, which are small but clear, presenting a contrast to the small and most obscure plates which used to be intended to illustrate Quain's Anatomy. But considerable improvement is yet possible in this direction. Altogether, though we do not consider the work perfect (what Manual *is*?), we entertain a most favourable opinion of it, and think that it well deserves the success and popularity which it has attained. Our only great regret is that we have not space to enter into it more at large.

(To be continued.)

EXTERN MATERNITIES AND LYING-IN HOSPITALS.

A REPLY TO CRITICISMS ON A COMMUNICATION TO THE DUBLIN OBSTETRICAL SOCIETY.

By EVORY KENNEDY, M.D., F.K.Q.C.P.

(Continued from page 358.)

What says the first authority of the present day upon zymotic diseases, Dr. Farr, Registrar-General, in his Report on Causes of Death in 1867, fifty years later, on this subject?—"The mere aggregation of people together in close apartments generates or diffuses the zymotic matter. Thus, *place lying-in women in close proximity* to each other, or mix them up with the patients of a general hospital, and they died of puerperal fever. Place many wounded men in a ward where cleanliness is neglected, and erysipelas, pyemia, gangrene spring up; imprison men within narrow walls, or crowd them in rooms, and typhus breaks out. The general and special hospitals of the country have been until quite recently erected without any special reference to the dangers accruing from the assemblage of great masses of sick people within the walls of one building, so that the efforts of the most skilful medical officers are frequently defeated." Again, Dr. Farr says—"The mere accumulation of masses of living people within narrow limits either generates or ensures the diffusion of epidemic disease." Again, page 220—"The suppression of the generating beds of disease, in unhealthy populations can scarcely fail to be efficacious. To suppress plague, suppress the wretched sanitary condition of Egypt; to suppress yellow fever, go to St. Thomas, New Orleans, and its other feeding grounds; to put a stop to epidemic outbreaks of cholera, cleanse the waters of India, and improve the condition of the population; to extinguish entire fever and typhus in our cities, extinguish the rookeries." And he might have added, to lessen the mortality by metria, if not to "get rid of the generating beds of this disease," reform the lying-in hospitals.

But to return to the attempts made to involve me in a discussion upon a collection of statistical tables, in which this higher standard of death-rates is dwelt upon as that to be aimed at, and with which we are called upon to rest satisfied. I once for all tell my commentators, that I shall fall into no such palpable trap; nor be led away from the true issue by any such—excuse the word—clap-trap.

I, therefore, disregard, with the utmost self-complacency, all their broad-sheets and narrow-sheets, teeming with figures and quantities, with a high death-rate, as the aim for us to attain. Nay, I will, if it be any comfort to them for treating the ponderous result of their labours cavalierly, I will admit them all *in globo*, and that without examination, as not germane to the question at issue, and only calculated to draw us aside from our great object, "how to lessen the mortality from metria." I want not to be reconciled to it, on the contrary, my object in coming before this Society, amongst whom I see so many of my alumni, is that of the Carthaginian of old, I would urge them to swear with me eternal hostility to our common enemy, metria, and, if possible, to unite the Knights Hospitallers, who have so strangely mistaken their antagonist in this discussion, to make common cause with me in our efforts at victory.

Sir, I may say generally that my commentators in this controversy have supported every one of my positions, although they may have cavilled at the extent to which I have carried them. When I say cavil, I mean that they have taken objection on points, and failed to grapple with the broad principles. They have attempted to draw the attention of the Society off from the discussion of a great question, boldly, and, I admit,

as my friend Dr. Beatty has said, startlingly, propounded, by involving it in a mass of what we shall term discrepancies of detail. They imagine that by showing a want of harmony and exact correspondence in all the collections of statistics they could scrape together, that they can break down the notorious facts which I arrayed before this assembly on introducing this subject—an array of facts, proverbial, and confirmed by the history of the great institutions of Europe, from their foundation to the present hour. Can they deny my tables in which the mortality in Paris, St. Petersburg, Vienna, Dublin, London, York, and Glasgow Hospitals are given, and the combined mortality of which is 1 in 44; whilst the death-rate ranges even so high as 1 in 18½ in Paris? Can they deny the average death-rate of the Dublin Lying-in Hospital, standing for the last 15 years at 31½? Can they deny that for four years of Dr. Collins's mastership, it stood at 1 in 186, showing what the true death-rate is—accidents of labour and diseases included, metria excluded? Can they deny that the death-rate of the South Union Workhouse Cottage Lying-in Hospitals had only amounted during the last four years to 1 in 233, and that no metria showed itself there during that time? Can they deny the report of the death-rates as given in Drs. Thomas and John Beatty's private practice, as furnished by Dr. Thomas Beatty himself, as 1 in 256? But, above all, can they deny, or, rather, have they not failed deplorably in their attempt to disprove, the mortality of the three cottage hospitals, Waterford, Limerick, and New Ross (to which we may now add Killarney), as standing at 1 in 232?

Sir, they cannot deny. They cannot vitiate. They cannot shake in the slightest degree one of these reliable and unanswerable bases of the reasoning upon which my conclusions are established. My conclusions, my deductions, and my propositions are the necessary sequence of their establishment. Sir, I am certain, and maintain without the fear of contradiction, that the effect of the ordeal my paper has undergone has been its entire confirmation.

As to the discrepant statistics adduced by them—their very discrepancy may be said to go a long way in proving the accuracy of mine. The laws of evidence have long established the fact, that want of exact harmony or correspondence in different testifiers is esteemed rather a corroboration than a denial of truth—a principle that is adduced as well by our ablest theologians in proof of the inspiration of Holy Writ, as by our petty sessions attorneys in the establishment of an alibi. But, Sir, it was a primary axiom in my days of pupillage, that “one affirmative proof overturned a host of negative evidence.” If the combination of philosophers who have been dealing for months with my propositions cannot reverse this axiom, then I submit that my propositions, and especially that one which has been so much cavilled at—the proportion of deaths to numbers and crowding—has been proved, aye, over and over again, by every great Lying-in Hospital in Europe. Why, Sir, my first impression on hearing it objected to was one of what I might describe provoked amusement, that any man could be found so innocent, or so obstinate, as to deny such a self-evident proposition. It was in this spirit, I confess that I, upon the third night of our sederunt, called the attention of the gentleman, who has the merit of first making this great discovery, to the case of Dr. Labatt's great mortality,—the very case to which he referred as corroborating the reverse. His mortality I repeat—1 in 63 in 1818—the year of the greatest number ever in the hospital. I showed him that the next year the habitat was complete, and the mortality rose to 1 in 33, although the deliveries were reduced 342; that it continued at 1 in 35 the year after, when the deliveries were again raised; and it gradually wore itself out in the course of the next two years, when the crowding was again permitted, and that in 1823 it again rose to 1 in 44.

I was in the hopes that this statement of figures would have

set the fallacy of confounding cause and effect, in this case at rest for ever. I imagined in my simplicity that ascribing the greater rate of mortality to the diminished number of patients, in place of the diminished number of patients to the greater mortality, was at an end, and that so preposterous a proposition should not be repeated. I have, therefore, to remind you that this step was taken to relieve the hospital from continuing to be the habitat of the poison. I am fully aware, Sir, that I am repeating myself, but I am doing so designedly, because, to my astonishment, the fallacy has been repeated, and dwelt upon again and again in this discussion, notwithstanding my exposure of it. Dr. M'Clintock repeated it; Dr. Beatty repeated it; and a host of other doctors, too numerous to mention, repeated it, and nothing is left to me but to repeat the refutation of it.

I purposely avoided dwelling much upon treatment in my former paper, my object being to grapple with the true nature causes, and means of prevention of metria. I thought, however, that the profession might have reason to condemn me if, in a treatise of this nature, I had entirely omitted to allude to it. My reticence in this respect has not relieved me from the usual fate of “mine enemy who writes a book.” My treatment has, in fact, been attacked as unmeasurably as my other views. I admit it is equally open to candid criticism, if this had been extended to it; but when the reverse has been the case, as it has in every instance in which my treatment has been called in question, I shall give these attacks but one general answer, namely, that when garbled extracts are taken and misrepresentations, proved by the context, put forward, I deem it both unnecessary and unbecoming to notice them, and I feel called upon to omit all mention of the critic and his objections—a practice that I also adopt when commentators outstep the fair bounds of criticism and descend to personalities.

By this simple plan the crime carries its punishment along with it, whilst temper and offensive personalities are prevented displaying themselves on my part, in what I esteem as a purely scientific inquiry, and one into which personal feeling should not be permitted for one moment to enter.

Why, Sir, if another night had been added to the debate, it is not impossible that the conclusions might have been arrived at by some latent essayists of the Knights Hospitaller ranks—some of the more courageous and *advanced* advocates of this *retrograde* movement in the nineteenth century—that the true cure and prevention of metria would be best accomplished by crowding all our parturient populations into large hospitals, and for this purpose not a moment should be lost in enlarging our existing lying-in institutions, and extending them upon the present principles, which have been found so satisfactory.

Some general objections have been raised to remodelling our hospitals, based upon such grounds as cost, expense, disinclination to change, architectural beauty, and so forth. They should be left as they are. The Deity has ordained that people should die epidemically; for his own wise purposes epidemics have always existed. Now, Sir, I shall not insult your understanding by combating such objections. Most of them were used over and over again against Jenner; and although the establishment of vaccination was retarded by them, it was not prevented. Could we now calculate the amount of human life and human misery saved by the introduction of vaccination and of that loss and misery caused by *their* opposition to it, this calculation might be turned to good account in the present discussion.

Sir, already has this discussion produced good fruit. The strong and universal opinion, I may say, pronounced upon the contagious nature of the disease, and the attention that has been more especially called to its spread by means of the indiscriminate mixture of the male pupils with the patients after attending autopsies, has, I understand, elicited an order pre-

cluding this practice, and thus for so far our common object has been gained—namely, the taking steps to endeavour to lessen the mortality by metria and other zymotic diseases. As I doubt not these precautionary measures will extend to other diseases communicable by contagion, the knight's service rendered by several of my critics upon this point reconciles me to much of their shortcomings in other branches of this inquiry. And if we applied the same principles of preventing the spread of contagion to the other equally important and equally obvious means by which contagion is necessarily spread through crowding together patients similarly affected, under a common roof, there would virtually be no question at issue between us. We should all be, on many points, of the same opinion, although still, I regret to say, on one or two essentials, "as far as the poles as under."

Sir, I might have appealed to their benevolence, love of science, and desire for improvement; as a motive for acquiescence in my views, and urged their adoption with arguments and persuasions thus adduced. But, Sir, in a severe inquiry such as this, I should by such a line only load my case "with superfluous armour, that encumbers rather than defends." I might tell them that communications had reached me from various quarters, such as that I now quote, in which Dr. Handyside, the distinguished surgeon for so many years to the Edinburgh Royal Infirmary, writes:—"I take this opportunity to congratulate you on the work as to wholesome village hospital wards instead of large maternities, in which, from the reports of the journals, I see you are engaged. Your experience and position ought to carry conviction, and it surprises me much to see so many of your profession opposed to the proposal. So far as my experience as hospital surgeon led me to see, we must in the end, be led to give up the large hospital buildings—Edinburgh, June 10, 1869."

But I shall not detain you with these from the result arrived at on the discussion of this subject in the Surgical Society of Paris, in which Trélat, Le Fort, and Jardier were the principal speakers.—See the *Gazette des Hôpitaux*, No. 67, 1866.

The following conclusions were arrived at:—

1.—It has been proved by statistics that the ravages of puerperal fever in lying-in hospitals are greater now than formerly. This can only be referred to the hospital atmosphere; therefore the infirmaries and hospitals should be reduced in extent, and assistance provided for the poor at their own houses.

2. Puerperal fever is infectious; and, therefore, hospitals conducted on the best principles may become the seat of great calamities.

3. Besides the usual sanitary measures which are recommended for hospitals, special precautions should be observed in lying-in institutions.

4. To avoid importation of disease, strict cleanliness should be observed. Empty wards should be thoroughly cleaned, not only the walls whitewashed, but the beds purified, &c.

5. To avoid the spread of disease the healthy should be removed from the ward, where any have been attacked, to small rooms for one, or at most four beds.

6. The attacked should be removed to a separate building.

7. If, nevertheless, the remaining females get the fever, the whole building must be emptied.

8. In cities where lying-in hospitals cannot be dispensed with, they must be small.

Since the above conclusions were arrived at by the ablest of our Parisian confrères, as we are informed by Oppert, "The administration in Paris have had the wards divided by double glass partitions; but, recently, they have gone farther, and recommended single bed-rooms."

This is striking at the root of the evil; and we trust that they will speedily go farther still, and have these bedrooms totally isolated and devoid of all closed communications, capable of sustaining and communicating a poisoned atmosphere from

the sick to the healthy. Anything short of this must prove inefficient, and end only in disappointment.

You see then, Sir, whilst we are discussing this question, it is deciding itself. Nay, Sir, it has decided itself; and decided itself, gentlemen, not as should have been the case, with the strenuous assistance of those members of the obstetrical branch of the profession who have ranged themselves to oppose my feeble efforts (to the knife), as they say themselves, but in the teeth of their resistance. Sir, the enlightened press of England, of Ireland, and of Scotland, has decided this question. It is an accomplished fact. Let the recusants hasten to join in our efforts, or they will rest under the inglorious conviction that they have wedded themselves not merely to an unsuccessful cause, but to one that is being stamped with the just reprehension of the medical and general press throughout this country. That great organ, that sits in judgment upon men's reasoning, their motives, and their actions, and draws its conclusions for the universal benefit—what does it say, gentlemen, upon the merits of this discussion? Do not be alarmed. I am not going to accumulate and reproduce the numerous articles that have dealt with it. I shall merely give you the brief view of one of the ablest of the London journals, the *Echo*, upon your own case in its article headed "The Harvest of Death, June 10th, 1869." "It is worthy of note," says the *Echo*, "that the idea of maternity hospitals, which were once so popular, has been exploded by scientific experience. It has been found that such institutions are merely nurseries for puerperal fever." Now, gentlemen, what say you to this? The press of England have arrived, without the assistance and in the teeth of your opposition, at this conclusion, that maternity hospitals are the nurseries or habitat of puerperal fever. But it is not done yet. Take to heart, I beseech you, the next paragraph of the *Echo*, and mend your hand in time. This, mark me, is the *Echo's* language, not mine. But here it is:—"The best hope of mitigating the danger under this cause (that is, the cause of continuing the maternity hospitals as nurseries for puerperal fever) is derived from the gradual but steady increase of medical knowledge, and the extinction of that time-honoured institution personified in 'Sairy Gamp.'" But now for the "keenest cut of all." "A new race of Gamps, intelligent and instructed, is one of the greatest social needs of our time."

Sir, in contrast to this view of the *Echo*, I cannot deny you the quotation of a private letter bearing upon the responsibility that rests with our profession in using their best endeavours in the prevention, as they do in the cure of disease. It was an acknowledgment written to a medical friend on receipt of his sanitary pamphlet lately published:—

"MY DEAR SIR,—Many thanks for your pamphlet. I am glad to see you feel a physician's duty extends beyond the cure of disease, and that the public have a right to look to him as well for its prevention. If our profession recognized and acted on this principle, generally, it would exercise a position, and earn an influence in the State commensurate with its true value. But until it does so we must not be astonished that they are treated as cyphers, not to say mere craftsmen by the State; when they rest satisfied with doing mere craftsmen's— I was going to say tinker's—work. I am glad to see, however, that you are an exception to this criticism.—Yours faithfully."

This, I think, requires no comment.

It would be amusing to reproduce some of the absurd accusations and imputed evil intentions with which I have been charged in this discussion. Mr. Sandham Symes, for instance, deals with the subject of architecture. At first I imagined his communication a hoax; but no, it is in too serious a strain. He seems really anxious to protect the ornamental buildings of the city, and like my friend Dr. Churchill, deprecates my proceedings in so precipitous a manner in a matter in which he graphically adds, "there has been as yet but a mere trifle of experience." But of what, think you, does he accuse me? Of nothing short of proposing to remove the beautiful structure,

the Dublin Lying-in Hospital, with its world-famed Rotundo, bodily, and replace it by cottage hospitals to be built upon its site, one of the worst sites that could be selected for such a purpose. Why, Sir, if made, such a proposal would justify my residence in an hospital raised by the eccentric Dean in another part of our city. This gentleman might, at least, have read my paper before presuming to criticise it, in which I distinctly recommend the converting the present hospital into an institution for diseases of females (with the power of admitting children), and suggested the high ground, the most elevated part of the Rotundo Gardens, as a most suitable site for the erection of isolated cottage hospitals for the labour patients.

(To be continued.)

RELAPSING FEVER.

THE Medical Officer of the Privy Council has issued a Circular on the present epidemic of this fever, in London, containing the following directions for local authorities:—

"1. The greatest personal predisposition to relapsing fever is given by states of poverty and privation; so much so, that the disease is often known by the name of famine-fever. Where destitution has not existed, or has been adequately relieved, relapsing fever is not likely to be epidemic.

"2. Relapsing fever is in a very high degree communicable from sick to healthy. The more confined the atmosphere in which sick and healthy are together, the more certain is the disease to be communicated.

"3. An attack of relapsing fever is greatly less dangerous to life than an attack of typhus. But where relapsing fever has attacked, and when all its acute symptoms are past, the sufferers remain for a while extremely weak, requiring that food and restoratives should be liberally supplied them; in default of which the feebleness left by the disease may often be of indefinite duration. This is the more important, because, where relapsing fever is epidemic, typhus often accompanies or follows it; and persons whom the relapsing fever has weakened not unfrequently fall victims of typhus.

"4. Relapsing fever is eminently a disease which cannot safely be treated in the houses of the poor; for in them, crowded and ill-ventilated as they generally are, and with inmates often insufficiently nourished, there must be every likelihood that the infection will spread. It is essential that under such circumstances the sick should at once be removed from amid the healthy. Ample hospital accommodation is therefore an indispensable condition for limiting the extension of the disease.

"5. Of duties which have to be discharged by local authorities in the several parts of London in relation to the present subject-matter, some are duties of Poor-law relief, and others are duties of general sanitary administration; but, as the former are done under direction of the Poor-law Board, only the latter are here adverted to. At present (as in all times when epidemic disease is prevalent or threatening) it is particularly important that powers conferred by the Nuisances Removal and other general Sanitary Acts should be well exercised by those in whom they are vested. Very detailed district inspection is most necessary. Everything practicable should be done, especially in all poorer parts of each district, to promote cleanliness of and about dwellings. The washing and lime-whiting of uncleanly premises, especially of such as are densely occupied, should be pressed with all practicable despatch. It is essential that over-crowding should, as far as possible, be prevented, and proper ventilation be enforced; and in these respects common lodging-houses, and houses which are sublet in several small holdings, will require particular attention. Above all, the attention of nuisance authorities is invited to the powers conferred on them by various sections of the Sanitary Act, 1866, with reference to infectious disease; especially to the powers conferred for purpose of disinfection, and for the conveyance of sick persons, and for the separation of the sick from the healthy.

"6. The parts of London in which at present cases of relapsing fever are believed to be numerous are Whitechapel, Bethnal-green, and St. Giles's.

"7. It is essential for the local authorities of London to know that at the present time the London Fever Hospital is quite or nearly full, and that in the face of such requirements as the next fortnight will most probably develop, neither the London Fever Hospital nor any of the general hospitals of London will be able to give them any important assistance in relation to their cases of relapsing fever."

INJECTION OF PUTRID MATTER, THE BLOOD OF TYPHOID FEVER, AND SMALL-POX—BY DR. COZE.

In one of the former numbers of the *Gazette* some selections were given from this gentleman's paper on the result of some experiments on the injection of the blood of diseased patients into the veins of animals. He has lately laid before the Society of Medicine of Strasbourg the results of some experiments on the subject of putrid infection. He says "that it is possible to produce with the blood of a person affected with putrid diseases disorders of a similar nature in animals." He states, that if the non-putrid blood of a patient who has died of putrid infection is found to contain vibriones, is diluted with water and filtered, and then injected under the skin of animals, death will result, at the latest, in fifty-six hours. During life, the temperature of the body of the animal is increased. He always found the liver to be the organ in which the largest number of vibriones existed. Injection of the blood into the trachea produced only a slight elevation of temperature. This he considered to be due to the action of the oxygen of the inspired air destroying the vibriones.

Non-putrid blood taken from a patient suffering from typhoid fever, containing vibriones diluted with water, and then injected in different ways, caused death in from fifteen to twenty hours. The temperature of the body rose rapidly to 41 degrees centigrade, and oscillated between 41 and 42½ degrees until death. After death, the lungs were found inflamed and the liver fatty. The blood was red and contained vibriones, the largest quantity being found in the blood obtained from the liver. There was a large increase in the number of white corpuscles.

The blood taken from a young man (who had not been vaccinated) at the period of pustulation of small-pox was examined with care, and vibriones of a very small size discovered. The liquid from the pustules contained no pus globules, but vibriones precisely of the same size as those observed in the blood.

The liver of an infant, two weeks old, which had died of small-pox, and the pustules on the skin, were found to contain vibriones. The blood and the fluid from the liver were injected under the skin of several animals. The temperature of their bodies was found to be less than when putrid or typhoid matters were injected. The animals became extremely thin. Death ensued much more rapidly in those animals into which the fluid of the liver was injected than in those in which the blood was employed—with the former in twelve days, but with the latter not for twenty. Large quantities of vibriones were found in the livers.

The ears of the animals, which were often pricked for the purpose of obtaining blood for examination, became nodulated in parts, and these nodules contained a serous fluid, in which vibriones, resembling those found in the human subject, were discovered. The blood was not so red as in typhoid infection, and more fluid than in putrid infection. The number of white corpuscles was increased; small purulent collections were found under the skin; the liver and kidneys were fatty; and the lungs hepatised in parts.

[These researches are of the greatest possible interest to medical science, and promise to elucidate many points connected with the determination of the true nature of disease. Coze sums up the results to be expected from the injection of infected matters, and states that there will be, 1st, Augmentation of temperature. 2nd, Alteration of the blood. 3rd, Development of vibriones. 4th, Fatty degeneration. 5th, Pulmonary hepatisation, and 6th, Increase in the number of white corpuscles.]—*Gazette Médicale de Strasbourg.*

WEDNESDAY, NOVEMBER 3, 1869.

THE COMING MEDICAL BILL.

THE abuses of medical study, education, examination, licensing, and practice, have so long and so sorely irritated the body corporate of the Profession that a sensible, practical, and decisive legislative remedy to the existing condition of things would be accepted by the Profession with a satisfaction which no other reform could inspire.

The admission of ignorant clownish schoolboys, by a farcical examination, to the study of a learned Profession, the permitted neglect of practical study, and the deliberate falsification of certificates of attendance, the framing of examinations for which a few weeks' strapping in the "grind-room" is the most sufficient preparation, and, lastly, the sending forth of practitioners capable neither of writing a letter or a prescription, or of treating the simplest ailment,—here is a catalogue of charges, needing hardly the form of proof, sufficient to justify the most sweeping and exterminative measures against the perpetrators which a disestablishing Government could deal out.

It appears that we are to have some such measure next Session, and it behoves us, and all who have seen the passing degradation of the Profession by the diploma-selling mania, to put forth its utmost strength, alike in favour of a decisive measure and in opposition to an expansion of the disendowment chimera, which might sweep away, at the same time, the time-honoured and upright body and the joint-stock diploma-selling corporation.

From what we hear of the projected measure, we are just as likely to be employed in saving ruins as in demolishing them, for it seems that whatever blow may be struck will fall alike on the best and the worst institutions. The project is as yet, we believe, in embryo, and we are only justified in treating it as a possibility which it is our duty to be prepared for. It is suggested that the Netley system shall be applied, as suggested by Mr. Rumsey, to the entire licensing system. That three Examining Boards, or one single peripatetic conclave,

shall sit in the three capitals, and shall examine all-comers for the *Licentia ad Practicandum*. Their examination is not, however, to be a substitute, but only an addition to the qualifying tests of licensing bodies. No candidate shall be examined by them without having previously obtained a diploma; and, on the other hand, no diploma shall qualify to practise without the capping testimony of the Central Board.

Who shall constitute the Board? Who shall pay them? On what subjects shall they examine? Who shall appoint them? What powers shall they have? These questions are all yet for discussion and settlement.

We shall return to the subject next week, and, feeling that the future of the entire Profession hangs upon the result, shall not spare space in its discussion.

ALLOCATION OF IRISH CHURCH FUNDS.

WE understand that the Council of the Irish Medical Association at its last meeting had under consideration the anticipated allocation of certain of the funds derivable from the disendowment of the Irish Church to medical objects. The expressed intention of Mr. Gladstone to apply a portion of these funds to the maintenance of lunatics and other similar purposes suggest their probable application to the purposes of the Poor-law Medical Service.

We believe that Mr. Gladstone has declared his intention not to apportion any part of the funds to the relief of "paupers;" but it has been specially and officially declared that persons availing themselves of medical relief under the Medical Charities Act are not "paupers," and we conceive, therefore, no more legitimate or useful direction which an expenditure could take.

Three objects suggest themselves at once, in respect of which an increased expenditure is greatly desired. The maintenance of skilled midwives in dispensary districts has already been suggested by Dr. Kennedy. Without doubt, the condition of poor women urgently demands some amelioration, and there could hardly be a greater boon to them and to the medical officer than the appointment of a person who could take charge of those natural cases to which it is utterly impossible that the medical officer can give due attention. But if the grant of public money should take this form, it will be absolutely necessary that the existing regulations for relief to lying-in women should be altered. At present the midwife is totally unconnected with the medical officer, and her attendance on a patient does not legally or really relieve the medical officer from his responsibility. The patient may, and often does, call for the attendance of the medical officer in addition to that of the midwife, and thus the services of the latter become an inconvenience and an incubus instead of a benefit.

Another direction in which it has been suggested that the funds might be expended is in the payment of the medical salaries. Without doubt the dispensary doctors would derive the most grateful relief in having the assessment of their remuneration taken out of the hands of the class which at present deals with the matter. To escape from the petty malignities and despicable meanesses of the reforming Guardians would be too happy a relief almost for realisation; but we can hardly expect or advise that for the purchase of such relief the public

funds should be spent to take from the ratepayers the just and lawful taxation which they are called upon to bear.

The last suggestion which the Council of the Association considered was the application of the money to building Dispensary Houses and Local Maternities.

There is no greater scandal than the condition of some of the dispensary houses ; but we think that fault should be met by the active interference of the Commissioners, and not by a public grant.

The Council of the Association is about to issue a Circular to Poor-law Medical Officers, asking for their advice on these points ; and as soon as full information as to the feeling of the Profession is acquired, it is intended that a deputation shall wait on the Government to give expression to the views of the Association.

THE CONTAGIOUS DISEASES ACT OF 1866, AND MR. SIMON.

ALTHOUGH there seems to be a great majority of our medical brethren on the side of extending the provisions of the above Act of 1866 to the civil population of the Kingdom, we are not at all sorry to find that some persons, such as Mr. Simon, of very great scientific reputation, seem rather inclined to question the data upon which are founded the arguments for such an extension of the Act. The first of Mr. Simon's arguments seems to us to be a very cogent one, although we know that exception has been taken to it. Mr. Simon says, that the State, which for its own purposes, keeps masses of the male population unmarried, cannot claim to be indifferent to the result : and he urges that it may therefore take exceptional measures to preserve the health of the soldiers, in order to save the pockets of the taxpayers. This argument is in so far a telling one, and explains the great difference which lies in the extension of an Act which was at first only proposed for the Army, to the whole of society. Soldiers are not allowed at present to marry at all. But no other male members of a free State are kept in such a state of enforced, and, we might almost add, perhaps, unnecessary, state of celibacy. No person in civil life has any social right to keep up such a distressing state of society as is implied by the maintenance of a class of women habitually selling their persons for hire indiscriminately to all comers. Were social questions better understood and the question of poverty, notably, for example, only once attacked in the positive method, it is quite possible that prostitution would soon be enormously diminished in its extent : and that the diseases connected with this wide-spread blot of modern societies might also be greatly diminished. Hence, we are inclined to go along with Mr. Simon, in his argument, that what may be quite admissible when applied to the Army, fails to be in any way evidently necessary as a measure to be recommended for application to society at large in this country.

Mr. Simon admits that it is not impossible that, by means of a well-organized regulation of prostitution, a good deal might be done towards warding off the ravages of venereal disease among the civil population. His reasons against adopting such a system, however, are threefold. First of all, he calculates that London alone, in order to cope with the extent of the evil, would require no less than 3,000 beds for venereal patients. But perhaps in this Mr. Simon a little exaggerates, since, of course, the advocates of the extension of the Contagious Diseases Acts maintain that very shortly a considerable diminution in the amount of the disease would be apparent, if only their system were efficiently carried out. The advocates of the French system point to the fact that much has already been accomplished by the operation of the Act in small military districts, though, of course, not so much, they admit, as would have been accomplished if the whole country had been

placed under the system, although the beds at the disposal of the authorities were only sufficient for a minority of the cases until the prevalence of the disease became diminished. And, hence, they deny the necessity of such great expenses falling on the ratepayers, as calculated by Mr. Simon ; and add that, in foreign countries, the problem is solved without so large a number of beds as Mr. Simon supposes to be necessary. Mr. Simon says that the severity of the disease would not be affected by this plan of extending the Act, but, in opposition to this, it has been asserted that the percentage of serious cases has become much lower of late in some places, such as in Devonport, since it was under the operation of the Act.

There is one point in which we must confess we cannot at all go hand-in-hand with Mr. Simon, and that is in his assertion that the extent of the evil of venereal disease has been exaggerated. Our own daily hospital experience flatly contradicts this phase of optimism. Not to mention the statistics attained by the inquiries made by the Harveian Society a few years ago, we may recall to mind the fact, that somewhere about 40 per cent. of the out-patients at Guy's Hospital were recently said to be cases of venereal contagion. Now, even admitting that a very large proportion of such cases were of but little importance, such as soft chancre cases, and mild cases of gonorrhœa, do we not continually come across cases of extensively ulcerated throat and soft-palate, of *ozæna*, of iritis, and ptosis, of some of the forms of amaurosis, of hemiplegia, and bone-disease, consequent upon syphilitic poisoning ; and do we not see in every surgical ward numerous cases of intractable stricture, the sad results of gonorrhœa in the male ? Is this the disease you call benignant, Mr. Simon ? Alas ! that it were anything of the kind : but, indeed, we have not yet mentioned the numerous cases of dead births and tainted children, which make up the tragedies of many a domestic hearth, or, further, those deplorable cases of hereditary syphilis, with which a single week's attendance at the London Ophthalmic Hospital at Moorfields would make any sceptic quite familiar. We are almost, indeed, tempted to say, that syphilis is *the most distressing* in its consequences of all human maladies. Fevers and consumption, or even cancer, assail us : and, after a period of time, varying from a few months to one or two years, we are no more : whereas the person poisoned by syphilis may for twenty or thirty years of after life go through a never-ending series of distressing lesions, such as ulcerations of the soft parts, destruction of the sight, nostrils, &c., &c. ; added to the contamination of his descendants, at any rate of the first degree.

It is well known that the Committee of the House of Commons last Session, after examining the evidence brought before them by the partisans for the extension of the Act, came to the conclusion that it was advisable that a slight extension of the Act should be made. But we must say, that we believe heartily, from our own experience of the working of a similar Act in Paris, that it is not the least likely that any such an extension would ever succeed if applied to such a large city as London. In Paris it has been found that whenever the prostitutes are examined regularly and treated carefully, and thus rendered more or less free from disease, straightway they do not seem any longer to attract the male sex. Hence there arise an immense body of secret prostitutes, all the more dangerous, that they fear (even at the ordinary hospitals, such as the Lourcine and others, not connected with the police), lest their diseased condition should render them amenable to the harsh discipline of the police, and cause them to be enrolled among the white slaves of men's appetites, and subject to being kept in a sad prison, St. Lazare, as long as the medical man of the prison pleases. In fact, we don't understand how it is, that our learned and enthusiastic brethren, advocates for police interference, do not see this. Let them make inquiries in Paris, and they will, we believe, despair of London being made free from venereal disease by such plans. Indeed, the subject is one of the deepest we can attack. It requires, we apprehend, a

greater knowledge of political economy than we fear is possessed by Mr. James Lane, Mr. Berkeley Hill, or almost any of the able gentlemen who are so anxious to carry out the extension can lay claim to. In our humble idea these gentlemen are, on this point, like those surgeons who care much about performing some operation upon a person suffering under phthisis pulmonalis. We have seen arms amputated in consumptive persons by such kinds of surgeons and, then—the disease went on to its fatal termination all the faster.

Do such gentlemen not see that the disease of prostitution is a terrible one, and that *there* we must look for the cause of venereal diseases being so rife? Lessen the amount of prostitution, then, if you can, and you will succeed in diminishing the amount of disease—and *not until then*. This is our last word. Study, O learned friends! a little more widely than you have hitherto done, the works of scientific teachers of the science of wealth, and of society, and we believe that you will be less intensely fond of mere details, and readier to listen to more well-laid plans for lessening the great curses of modern community, late marriages, prostitution, and that infernal curse of our race, widespread destitution and its intolerable evils. Be not ashamed of saying, "I am ignorant." Socrates and Newton said that long ago; and hence they were prepared to learn something new at all times of their lives.

SCOTLAND.

SIR JAMES Y. SIMPSON, ON HIS OWN CAREER.

EDINBURGH has been honouring itself in doing honour to one of her most brilliant citizens and Professors. Sir J. Simpson has not only sustained, but increased the reputation of the University. His brilliant career reflects lustre on the chair he fills, the seat of learning of which it is a part, the city where he dwells. The whole civilized world has laid the tribute of acknowledgment and gratitude at his feet. It only remained for those who knew him best to give him the only honour in their keeping. We regret we have not space for a detailed account of the whole proceedings; but we cannot resist giving his speech, in which he sketches his own career: he said—

MY LORD PROVOST AND FELLOW-CITIZENS, I am utterly unable to express to you in adequate terms my thanks for the honour which you have conferred upon me. Your Lordship has spoken of the honour as not great in itself. I look upon it as one of the greatest which I have ever received; and believe me, that if I cannot speak my thanks for it sufficiently with my lips, I feel these thanks deeply and intensely in my heart. (Applause.) Honours like this become the more prized and precious in proportion as they are the more rare in their bestowal. This view only tends to enhance my gratitude on the present occasion; for though the Lord Provost, Magistrates, and Town Council of the city of Edinburgh have in times past enrolled on their list of honorary burgesses some princes and peers, and a proud array of illustrious statesmen and soldiers, legislators, lawyers, and litterateurs, they have rarely or never till to-day bestowed, I believe, the same distinction upon a medical practitioner in their own city, or a professor in their own University. (Applause.) It is fully forty years since I came first to Edinburgh, and entered its University as a very, very young and very solitary, and almost friendless student. (Applause.) But matters are now so entirely changed and reversed that I feel at this moment as if, in the distinction which you have conferred upon me, the community of Edinburgh as a body offered me the right hand of cordial fellowship and the kindest felicitations. Nor was my original ambition in any way very great. After obtaining my surgical diploma I became a candidate for a situation in the west of Scotland, for the attainment of which I fancied that I possessed some casual local interest. The situation was surgeon to the small village of Inverkip, on the Clyde. When not selected, I felt perhaps a deeper amount of chagrin and disappointment than I have ever experienced since that date. If chosen I would probably have

been working there as a village doctor still. But, like many other men, I have, in relation to my whole fate in life, found strong reason to recognise the mighty fact that assuredly

"There's a Divinity that shapes our ends,
Rough hew them how we will."

Or, in the language of the French proverb, "Man proposes, but God disposes." (Applause.) Through the ceaseless love and kindness of a dear elder brother, and in consequence of gaining the Macpherson University Bursary, I was enabled to study for some time longer at the University and obtain my medical degree. Professor Thomson—to whom I was then personally unknown, but to whose advice and guidance I subsequently owed an endless debt of gratitude—happened accidentally to have allotted to him my graduation thesis. He approved of it, engaged me as his assistant, and hence, in brief, I came to settle down a citizen of Edinburgh, and fight amongst you a hard and uphill battle of life for bread, and name, and fame; and the fact that I stand here before you this day so far testifies that in this arduous struggle I have won. (Applause.) Some seven or eight years after my graduation, and in this very room, all the fortune and destiny of my future life were one forenoon swayed and settled by a vote of the Town Council of Edinburgh, when they elected me Professor of Midwifery in the University. Of the councillors who then voted for me, I have the pleasure of recognising as still among you my friend the Lord Dean of Guild, and your prospective Lord Provost, Mr. Law. (Applause.) And to no citizen was I, at that time, more deeply indebted for success than to the gentleman who now sits on your Lordship's left hand, our esteemed member of Parliament, Mr. McLaren. (Applause.) Assuming on that occasion the character of a judge and not of a mere witness or testimonialist, and speaking in behalf of many of his medical colleagues, a professor who is still a very eminent member of the Medical Faculty strongly and dictatorially urged in print upon the patrons that the fate of the University was at stake if they ventured to allow their votes to fall upon me. (Laughter.) But I fondly hope that my connection with the University which you then willed and ordered, has not decreased either its reputation or its status in the world of science. (Applause.) On the day of election one of the patrons eagerly argued in this hall that if I were chosen as Dr. Hamilton's successor the hotel-keepers, merchants, and others in the city, would have good reason to complain, as I could never be expected like him to induce patients to come occasionally from a distance to our city. But I think this prophetic objection has been even more fully gained than the other; for I believe I have had the good fortune to draw towards our own beloved and romantic town more strangers than ever sought it before for mere health's sake—(applause)—and that, too, from most parts of the globe—from America and Australia, from Asia and Africa, and from the various kingdoms of Europe. (Applause.) Your Lordship has alluded, in too flattering terms, to some portions of the work which I have been permitted to do in the course of my professional life. I only wish my deserts were more worthy of your kind eulogy; for sometimes, when I look back and reflect, I feel regret and dismay that my avocations and my idleness have prevented me from doing more for the promotion of a science and art, which, like medicine, calls aloud for so much devotion and study from its followers and votaries. You adverted to the discovery of the anæsthetic effects of chloroform. Perhaps you will allow me to state that there are various manufactories of it in Great Britain, and that a single one of these located in Edinburgh makes as many as 8000 doses a day, or between 2,000,000 and 3,000,000 of doses every year—evidence to what a great extent the practice is now carried of wrapping men, women, and children, in a painless sleep during some of the most trying moments and hours of human existence—and especially when our frail brother-man is laid upon the operating table and subjected to the tortures of the surgeon's knives and scalpels, his saws and his cauteries. (Applause.) Acupuncture is not ten years old, but during that brief period it has spread over the surgical world to a greater extent than its predecessor, the ligature, did in one or two centuries. Besides, it has already led the way to other advances in surgery. In relation to another question to which your Lordship adverted—viz., the proper construction of our hospitals—let me merely remark that when such a simple operation as amputation of the forearm is performed upon a poor man in the country and in his own cottage home, only about one in 180 die; but the statistics of our large and metropolitan hospitals disclose the stern and terrible truth, that if these men had been inmates of their great wards, thirty of them, or

about one in six, would have perished—a fact, among many others, calling earnestly and strongly for some great reform in our large hospitals, if these institutions are to maintain their ancient character as the homes of charity and beneficence. (Applause.) You have spoken in too kindly words to the reputation which I have happened to acquire in consequence of some of these researches and investigations. Of the value or the reverse of such researches, and their probable bearings upon human science and progress, no author is perhaps himself an adequate judge. It has been often, however, adduced as a sage and sound remark, that a man may sometimes see, as in a mirror, a forecast of the relative esteem in which his works and writings will be eventually held by future generations, by looking at the relative estimation in which he and they are held in his own day by foreigners, and by foreign nations and foreign schools, who, unbiassed by personality, reduce all objects at once to their just proportions and true value. If I dare to risk myself to such a test, I should have some reason to hope that what little I have done in my profession may yet perhaps enable me to leave some slight "foot-prints on the sands of time"—(Applause.)—for I have had I believe, more foreign academic honours and distinctions accorded to me than have fallen to the lot of my medical con-temporaries. (Applause.) For my own part, however, I regard it as a far higher and greater gratification that to-day, and at home—not from strangers and foreigners, but from you, my own townsmen, who live in the same community with me, and know me personally, and all my outgoings and incomings—I have received the honour which you have conferred upon me—(Applause)—and I received it in the spirit of your Lordship's interpretation of its object—not as a testimony of esteem offered by you to me as a professor and physician merely—but also as a man. (Applause.) It is specially in this last light that I rejoice in thus standing here before you this day, and accepting from you this casket, which I shall have sincere pride and pleasure in transmitting down to the keeping of my sons. (Applause.) But I have detained you too long. Before concluding allow me only one remark more. The distinction which you have bestowed upon me is, in my eyes, greatly enhanced in value by the fact that, my Lord Provost, it has been passed to me through your hands—(Applause)—the hands of a chief magistrate who will leave so deep an impress of good upon this city and this era. (Applause.) For I know and feel with many of my medical brethren that during your term of magisterial office you have initiated among us a course of sanitary and hygienic improvements that will betimes add mightily to the health and well-being of the inhabitants of Edinburgh. (Applause.) Besides, I feel proud that my burgess ticket bears so distinguished a name as that of William Chambers—a name that in future times will doubtless be held in deep estimation wherever the English language is read and spoken—as that of the man who, first among us here, instituted, founded, and fostered that marvellous system of cheap literature and journalism which seems destined to exercise so powerful and gigantic an influence on the history of human progress; and in the march onward of human education and human civilisation. (Loud applause.)

Sir James Simpson then shook hands with the members of Council, and the proceedings terminated with three cheers for the youngest burgess.

JOSEPH JACKSON LISTER, F.R.S.

THIS much esteemed gentleman has died at an advanced age. In the last generation his name was amongst the foremost. He was the father of the new Surgical Professor at Edinburgh.

EDINBURGH UNIVERSITY GENERAL COUNCIL.

THE ladies have won the day. After full discussion, the Council has agreed to the initiation of separate medical classes for ladies in the University. There was opposition, as we stated last week, led by Rev. Mr. Phin, who was ably supported by Dr. Andrew Wood. Professor Masson, however, proposed a resolution permitting the classes, which was eventually carried.

GLASGOW AND ABERDEEN.

THE contest, as we have stated, will be close. Neither

candidate has responded to the advances of the medical graduates, who are, as we go to press, holding another meeting. They are expected to throw their weight in the scale of the candidate who is prepared to pronounce most decidedly in favour of medical reform.

DR. INGLIS, the new Professor of Midwifery at Aberdeen, opened his course last Wednesday.

THE Edinburgh University Court has approved of the appointment of Dr. Afflech, as assistant to the Professor of Medical Jurisprudence.

DR. DUNLOP, was, last Wednesday, elected to the Chair of Surgery, in Anderson's University, rendered vacant by the removal of Dr. McLeod to the University of Glasgow.

THE General Council of the University of Glasgow met on Wednesday last. A report was received from the Committee of Graduation recommending that more facilities be given, and that the degree of B.A. be restored. The report was approved and transmitted to the University Court.

Notes on Current Topics.

The Medical Council.

THIS body is about to move. The executive committee have held a meeting and resolved to ask Lord de Grey to receive a deputation on the question of amending the Medical Acts. It is impossible to imagine that the Council will so far rise to the occasion as to proclaim their own uselessness, or to admit how little they have done. They will, no doubt, proclaim that they have really but little power, and the President of the Privy Council ought, therefore, to be informed by other means that they have not done what they could. They were asked last Session to pass a resolution recommending the corporations to allow their members to select their representatives. This they did not do, although it is undeniable that the corporations have for the most part respected such recommendations as the Council have made, and the Council, as a rule, delights in recommendations. To shelve so simple a proposal for reform was a betrayal of the Profession, and we fear that nothing but an Act of Parliament will place the Council in the position of a *bona fide* representative body.

The drift of what is coming, of what has roused the Council to action, is seen in the following Parliamentary notices for next Session.

Sir John Gray gives notice of—

"A Bill to amend the Act under which the Medical Council of Education and Registration is now constituted, by altering the mode of appointing the members, and by increasing the powers of the Council, with a view to securing a uniform system of granting licences to practise the medical and surgical profession."

Mr. Graves proposes—

"To call attention to the constitution of the British Medical Council, established by the Medical Act of 1858; and to the necessity of legislation for conferring on the graduates and licentiates of the Universities and medical corporations the power of electing their own representatives on that Council."

English and Irish Poor-law Service.

THE quarterly meeting of the Poor-law Medical Officers Association of England was held last Wednesday evening at the Freemasons' Tavern.

There was a good attendance, and some M.P.'s and other influential gentlemen lent their aid. The President related his investigation into the Irish system, and that was generally considered to be far superior to the English. He thought that continued agitation should be kept up until Government were compelled to move in the matter.

Mortality of the Quarter.

THE Registrar-General's Quarterly Return is just out. The weather of the quarter was warmer and drier than usual. The deaths in London numbered 19,207, as against 19,149 in the corresponding quarter of 1866. Scarlet fever carried off 1,770 persons in the metropolis, and was also proportionately fatal in other places. In 1868, infantile diarrhoea was the prevailing disease. The total mortality of England in the third quarter of the year was 114,654, being 15,848 less than in the same period of 1868. The rate of mortality was 20·77 per 1,000. In 1868 it was 23·89. The average of the season is 20·63. The Registrar-General calculates that thirty large towns, with a population of two and a half millions, have lost annually 32,735 persons more than would have died had their mortality been only that of the healthy districts of England.

Vaccino-phobia.

At a meeting over which Mr. Chambers, M.P., presided, somebody described small-pox as "a blessing." Would he wish a prayer for its diffusion introduced into the services of the Church? Few would heartily join in a petition to the Dispenser of all Good for an attack of confluent small-pox.

The vaccino-phobiacs are disseminating their poisonous tracts with an energy worthy of a good cause. It is well, therefore, for medical men to be alive to what may be said to them by patients. In our columns lately several books on the side of common sense have been mentioned. We would introduce to the reader's notice another—a small one, which we have come across in an unusual way, but which may do good service in its place.

It is an Essay on Vaccination by Mr. J. H. Watson, M.R.C.S., of St. John's Road, Hoxton. It is published by subscription, so that it is not advertised in the usual way. We would, however, advise those who can afford to do so, to send the author five shillings worth of stamps for a copy. The essay is such as will do to lend any patient afflicted with vaccino-phobia, and may be more useful than works of far greater pretence for such a purpose. It may be, too, that such subscriptions may encourage a young author and worthy member of the Profession. The little book contains the opinions of many besides Mr. Watson himself.

The University of Cambridge and the Medical Council.

WE have more than once commended the example of Cambridge in giving all members of her Senate a vote in the election of representatives in the Medical Council. An election, consequent on Dr. Paget's acceptance of the Presidency, was fixed for last evening.

A Syndicate has been appointed to consider certain questions referred to the University by the General Medical Council, and it is said that other licensing bodies will be communicated with. A few slight changes would attract large numbers of students in Medicine to the elder English Universities. We should be glad to see such changes introduced.

University College Hospital.

SOME time since Dr. George Harley, F.R.S., retired from his Professorship of Medical Jurisprudence at University College, partly from failing health. Though we have now to congratulate him on his restoration, he is about to resign the office of Physician to the Hospital, in order to devote all his time and energy to his increasing private practice. In him the College and Hospital lose a man of mark—an earnest student in the best sense of the word. For fifteen years he has laboured with unremitting zeal. During that time he has achieved all the honours coveted by men in such positions, and now has his reward in the esteem of his colleagues and the Profession generally. We rejoice alike in his restored health and the reason assigned for his resignation.

Composition of Portuguese Beef.

THE contractors who supply the military authorities in Dublin with beef and mutton import large numbers of oxen from Portugal. Some doubt having arisen as to the nutritive properties of the beef furnished by the Portuguese cattle, a committee of officers was appointed to investigate the matter. Specimens of Portuguese beef and Irish beef—each of equal weight, and taken from the same parts of the animal—were boiled and roasted under the same conditions. In boiling, the Portuguese lost less weight than the Irish; but by roasting, the reverse results were obtained. Specimens were also submitted (numbered only) to Professor Cameron for analysis. His results may be summarised as follows:—

	No. 1. (Irish.)	No. 2. (Portuguese.)
Water	72·75	74·00
Muscular fibre	15·47	15·29
Gelatinous bodies	2·06	1·98
Albumen (and a little colouring matter)	2·27	2·20
Extractive matter, kreatine, &c.	1·97	1·87
Fat and oil	4·28	3·50
Saline matter	1·20	1·16
	100·00	100·00

These analyses refer to the clear flesh, separated mechanically from the adipose tissue. The fat of the Irish beef was white, that of the Portuguese, yellow. The composition of fresh beef, according to the mean of all Continental analysis, is as follows:—

Water	73·40
Albuminous matters	17·40
Gelatinous matters	3·30
Fat	2·87
Extractive matters, &c.	1·43
Ash	1·60
	100·00

Irish beef would appear to be very rich in solids as compared with the average quality of the flesh of the ox.

Eating Hair.

A WOMAN, aged 30, died last week, in Lincolnshire, who had been under-medical treatment for some time for a supposed tumour in the stomach. On a *post mortem* examination a solid mass weighing nearly 2lbs. was taken from the stomach. It formed a rough mould of that organ and the termination of the œsophagus. It was found to be composed of human hair, and one of her sisters states deceased was in the habit of swallowing her own hair. It is not often such a case is met with, but in veterinary practice is more common. We can recall but one or two instances. A horse dying from such a cause is within our experience, and a goat thus destroying itself has been mentioned to us by a friend.

Proposed Medical Mission for London.

DR. BURNS THOMSON, of the Edinburgh Medical Mission, addressed a number of gentlemen the other night in the Theological College of the English Presbyterian Church, for the purpose of explaining the manner in which medical mission work was carried on in large towns. His address excited a good deal of interest, and it was stated that in addition to the agency of this kind in Edinburgh, medical missions had been organised in Aberdeen and Liverpool, and that by means of them great good had been effected amongst a degraded portion of the population. It was proposed and agreed to that steps should be taken for establishing a medical mission in London, in some densely populated locality, and a committee was appointed to make the necessary arrangements with a view to this.

The Cholera at Peshawur.

THE *Delhi Gazette* of Sept. 23 says:—"We still continue to receive unfavourable accounts of the visitation of cholera at Peshawur, and though the latest details are more encouraging than the former, we yet look forward with anxiety to the result. One correspondent states that there were upwards of fifty attacked among natives and Europeans a day or two before he wrote, and another informs us that of fourteen Europeans attacked only six succumbed. This is so far hopeful, and we anticipate relief from the removal of the troops into camp. We learn further that the Punjab Government has consented to the occupation by the military of Cherat, a hill some two marches distant from cantonments; and also that all the officers on leave from the garrison have been recalled. The disease is said to have visited Attock also. The troops at Abbottabad were removed into camp as a precautionary measure only, and to keep them away from the vicinity of bazaars and other native influences."

Scarlet Fever at the Children's Hospital.

WE regret to hear that scarlet fever has broken out in the Children's Hospital. Notice was at once sent to the parents of patients in a fit condition to remove them; by isolating those attacked with the epidemic and preventing all communication between the attendants in that and other wards, it is hoped the outbreak will be confined to the one ward.

Mr. Peabody.

UNIVERSAL regret is expressed that the health of Mr.

Peabody since his return to England, nearly three weeks ago, should again have failed. As he became worse the Queen telegraphed for information, and, to satisfy the anxieties of the sympathising public, bulletins have been regularly issued, signed by Dr. Gull and Mr. Covey, who are in attendance. The last stated that the improvement previously reported continued. May he be speedily restored is the universal desire.

Representation of the Universities of Glasgow and Aberdeen.

THE *Lancet*, which has always possessed Liberal principles, has made an attempt to prejudice medical graduates in favour of Mr. Gordon, by professing to show that he is more ready than Mr. Smith to undertake any effort to redress professional grievances. Such a statement is as unworthy of a public journal as it is characteristic of the trimming propensities of our contemporary. Mr. Smith in a public address has professed himself ready to play the part of advocate on behalf of the profession, and has appealed to the medical electors to promote their interests by supporting the "party of progress." Mr. Gordon acknowledges there are "matters of legal regulation, in regard to which the members of the medical profession have just cause of complaint," and as to these he would seek redress.

So far, Caesar and Pompey are very much alike. The test question will be whether either will endeavour to make the Medical Council a really representative head of the profession. We would advise the medical graduates not to vote until they have a pledge on that question.

SCARLET fever continues to increase in the metropolis.

DR. RISDON BENNETT has been elected a Governor of St. Thomas's Hospital on his retirement from the staff.

A LONDON meeting to initiate a Syme testimonial is to be held on Wednesday, the 10th, at St. James's Hall.

IN January last there were 45,153 insane paupers in England and Wales.

ON Monday it was reported that the Emperor Napoleon had experienced a return of his rheumatic pains.

A CORRESPONDENT says that bodies for dissection in the Paris schools only cost about five francs each.

DR. ROBERT LEE has placed his anatomical and pathological collection in the Museum of the University of Cambridge. This collection includes those remarkable directions which once gave rise to so much controversy.

No improvement at St. Bartholomew's. The *status quo* is maintained, but the general press has so fully exposed the abuses that prevail that something must be done. There is but one cure, a great enlargement of the staff.

A LIQUID chemical compound for street sprinkling has been tried in Philadelphia. It is said to form a union with the dust, solidifying it, and rendering all pavements,

especially wooden, more durable. It is also claimed that it purifies the air, preventing contagion. The cost is but little, and it need be used only once a day.

A CORONER'S jury last week reproved a medical man for inhumanity in not going when sent for to a case that proved fatal. The jury overlooked the fact that the doctor was ill in bed and could not go. The inhumanity consists in thus slandering a professional man by their stupid verdict.

DR. JOSEPH JONES, Secretary of the South American Historical Society, has prepared an estimate of the losses of the Confederate army during the war, which is as follows: Killed, 53,773; wounded, 194,026; prisoners, 202,283. He thinks that if the deaths among the discharged for wounds and diseases, and among the sick and wounded, and wounded on furlough, be added, the grand total of deaths in the Southern army during the entire war did not fall short of 200,000.

THERE is to be a change made shortly in the medical officer of Chatham Dockyard. Staff-Surgeon John King, in consequence of ill-health, has retired, and has been succeeded by Staff-Surgeon Henry Piers, M.D., at present stationed at Melville Hospital. Dr. Godfrey has succeeded Dr. Piers at Melville Hospital. Until the recent retrenchments were made in the Dockyard there was an assisting-surgeon as well as a staff surgeon; now all the duty is performed by one surgeon.

A PRIVATE letter from the West Indian Squadron by the mail steamer Tasmanian, which arrived at Plymouth on Wednesday night, says:—"You will be glad to learn that the epidemic of yellow fever is decreasing rapidly. The last victims were an assistant surgeon (Army), Clark, and on his death his wife (only nineteen years old) refused to eat or drink, and death followed in a few days. They left a young child to the care of strangers. A sad, romantic story. Afloat all as healthy as possible."

WE understand that the operation of Cæsarian section was performed at Brentford, on Thursday night last, by Dr. Palfrey, upon a lady who was the subject of profound pelvic distortion caused by rapidly increasing mollities ossium. We shall, at no distant date, publish a full report of this most interesting case.

THE Provincial Medical Schools of England have had a large entry, so that there is a considerable increase in the number of medical students over the last few years. More than 1,550 gentlemen are pursuing their studies in the Metropolitan and Provincial Schools together, and as the returns are not yet quite complete, perhaps the number may reach 1,600. Of these between 1,200 and 1,300 are in London.

THE new number of the *Practitioner* contains an article on the action and uses of ipecacuanha, which will probably excite some attention. The author, Dr. Douglas Phillips, has found it one of the most certain of our remedial agents in checking profuse secretions from all mucous

membranes. In diarrhoea, dysentery, and other diseases, besides all cases where expectoration is a prominent symptom, he relies upon it alone. Several cases are published. The *Medical Mirror*, for November contains two cases of esthiomene, by Dr. Waring Curran. Both the writers we have named have paid much attention to practical therapeutics.

WE have already drawn attention to the proposal to establish an Hospital for Incurables, near the city of Oxford. We are glad to find the project is in a fair way to success. Three thousand pounds have already been subscribed, and active committees in Oxford and London, formed under the presidency of the Duke of Northumberland, with the Bishop of Oxford as visitor, and distinguished members of the University Senate and the neighbouring gentry on the Council.

IT is rumoured that Mr. Erichsen will propose that thirty Fellows should sign a requisition for a meeting of the Fellows of the College of Surgeons according to the motion he is to bring forward. This is no great restriction, as thirty would most likely be ready to join in calling a meeting on an important subject, though, considering the trouble of getting the same, twenty would suffice. It is further said that the Council will be allowed a veto on any such meeting. We sincerely hope this obstruction will not be permitted. The Fellows may want to discuss the conduct of the Council.

AT an inquest at Mansfield the other day the Coroner censured a medical man for taking aside a woman to question her respecting the deceased before giving a certificate of death. It may be fairly replied that it was more delicate to speak of an abortion in private, than before the male relatives who accompanied the woman. Unfortunately, it turned out there had been foul play, and the doctor's certificate would have been better withheld, especially as he had only seen the patient once. He seems to have entertained a suspicion for a moment. If so, it would have been better not to speak to anyone who might be involved privately. Otherwise his delicacy is easily understood.

Correspondence.

LARGE FAMILIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It appears to me that J. D. N. has well expressed the opinion of a large section of the community, when he says that it would often be a highly expedient matter if married persons could at will pause before adding too rapidly to the number of their offspring. He well says that there can only be two ways of doing so: 1st, the plan of abstaining altogether from the nuptial couch; and, 2nd, some plan for avoidance of impregnation.

As to the first of these remedies, no doubt it is rather difficult: still there are some persons who are daunted by no slight matters, and who are ready to abstain altogether from what they call "the lusts of the flesh," if only duty call them clearly to do so. I have met with not a few in this country who said that if population must be restrained somehow, they considered that this was the only legitimate method, consistently with their early training, that could be adopted by them. To such persons, of course, the Malthusian of to-day can only say, Follow out the dictates of your conscience: but don't deluge us with children, destined to be miserable and perhaps vicious; and, if

you consider any other method, save abstinence, vicious and degrading, by all means be abstinent, if your partner agree to it.

But does not this seem, after all, to be rather an affair of sentiment than of great utility? It is, certainly, a grave affair to overcrowd the labour market; but it is rather a matter of taste than of supreme importance to others, whether a married couple make use of abstinence or of innocuous artifices. It appears from our experience of French life, that the number of abstainers in married life is but few; and that the number of persons who commit what is called in France "fraudes" is legion among our neighbours on the other side of the Straits of Dover. They seem generally (if we may dare to say so, even in a medical journal, in this land of puritanical observances) to make use of the plan for which a celebrated Scripture character in the Old Testament was suddenly struck dead. I don't remember chapter and verse, although the name is familiar, and has served as a misnomer to a vice common enough in our lunatic asylums. Then, again, the illustrious Raciborski asserted, we all know, that impregnation only takes place for about ten days after menstruation in the human female: and some persons believe that (M. Mayer, in his "Rapports Conjugaux," e.g.) this plan is quite sufficient to restrain any additions to the family. Would that this were true! but we should not like to rest on such a broken reed. The first mentioned of these plans is, I believe, the plan commonly resorted to throughout France, or that country whose population increases more slowly than any European State. None of our slightly violent writers can write more against the supposed evil effects of these practices on the health of the community than has been done by Dr. Mayer, above quoted, or by a recent author in a work entitled, "Des Fraudes dans l'Acte de Generation," published at Paris.

Were it even proved, however, (and it may be), that such "fraudes" were prejudicial to human health, we must remember that overcrowding is productive of early infantile mortality, fever, and chronic poverty; so that, after all, it is probable that the slight injury done by such practices to the health is more than counterbalanced by the severe agonies and human sufferings saved by this form of *prudential restraint*. As to late marriages, they mean misery and prostitution, venereal disease, and masturbation on a large scale. "*Naturam expellas furca tamen usque recurrit.*"

I remain, Sir, your obedient servant,

A. G. I.

London, Oct. 29, 1869.

THE MULTIPLICATION OF MANKIND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Mr. Biddle has brought to the discussion of the question of the rate of increase of the human race in primitive times exactly that kind of argument which sincere devout people, whether Christians, Jews, Mahomedans, or Hindoos, who never have, or never ought to have, been far from their native place, might have been expected to rely upon—namely, "it is written." It is, it seems, found written in the Bible that in the course of 270 years the progeny of one man (Abraham) increased sufficiently to form a population (the Hebrews in Egypt) capable of furnishing 600,000 fighting men, and consequently numbering in all 3,000,000 at the least. Such being written down as the pace at which the Hebrews multiplied in the land of Goshen, it must be admitted, argues Mr. Biddle, that Shem, Ham, and Japhet, with their wives, were quite capable of propagating at a rate which, in the course of the 450 years that intervened, according to him, between the descent of Noah and his family from the Ark and the establishment of the Egyptian kingdom, would suffice to produce the "immense multitudes necessarily supposed in the formation of great monarchies."

But all the transactions connected with the multiplication and preservation of the Hebrews in, and their exit from, Egypt were of a miraculous character—that is, they were, according to Holy Writ, accomplished by the direct agency and superintendence of God. As such, they are consequently inadmissible for the purpose of establishing a natural rate of human propagation. This circumstance, however, points to an easy solution of the supposed difficulty—namely, that the multiplication and preservation of the descendants of Noah may very well have been equally miraculous with those of the descendants of Abraham.

Nevertheless, even this preternatural rate of increase of the human family, which, according to the calculations of Mr. Biddle, may have resulted in a total population, for the entire earth, of some 85,000,000, would be quite insufficient, since Egypt was not the only great ancient monarchy. There is evidence that in Chaldea, Persia, India, and China great empires were also formed as early as the period at which Mr. Stuart Poole placed the establishment of the Pharaonic Kingdom, to say nothing of Europe, America, and ultra-Nilotic Africa, which, for aught that is known to the contrary, were as thickly populated as any part of Asia.

The truth is, as the Duke of Argyll freely admits, with all who have paid any attention to archaeology, that the Biblical chronologies are utterly incompatible with the facts of ethnology. Extant pictures in the rock tombs of ancient Hermopolis (now Beni Hassan), in Egypt, exhibit representations of several negro races possessed of exactly the same racial characteristics which they have at the present day. But these paintings are of the time of King Usurtaxen I., whose date, according to Mr. Stuart Poole, is 2030 B.C., which is only 263 years subsequent to Noah. Can any one venture to pretend to believe that these 263 years were, in the natural course of things, sufficient for the development of the negro from this white man, or *vice versa*, whereas, during the forty centuries which have all but expired since the grottoes of Beni Hassan were painted, the black and other races of North Africa have remained unchanged?

London.

Yours obediently,

F.A.S.L.

Medical News.

AT MAURITIUS IN THE EPIDEMIC.—Dr. Blaxall, surgeon of Her Majesty's ship *Urgent*, has made a report of a visit to the Island of Mauritius towards the end of the epidemic of malarious fever in 1867. In the short period from the 1st of January to the 6th of July the district of Port Louis lost 16,602, out of a population of 80,000, or one soul in every five; the district of Pamplemousses, 4,344 out of 60,000; Rivière du Rempart, 1,656 out of 21,000; Black River, 1,960 out of 19,000; Flacq, 892 out of 46,000; Plaines Wilhems, 1,027 out of 31,000; Moka, 1,030 out of 20,000. The two remaining districts, Grand Port, with its population of 41,000, and Savanne, with 23,000, lost none, except persons who went thither from their own districts while suffering from the fever. The exemption of these two districts is obviously well worthy of consideration. They form the south-eastern part of the island, and are separated from the remainder by high land and an extensive woody district. The railway from Port Louis to Mahebourg, the principal town of Grand Port, makes a gradual ascent to Curepipe, about 1,800 feet above the level of the sea, and then descends towards Mahebourg. Persons sick of the fever were carried there, and communication went on daily, but the disease never spread. Perhaps if the railway had gone through a cutting the poison would have been waited along the level. The fever attacked all classes, but it was principally fatal to the ill-fed and badly housed. Owing to the great numbers ill, medical attendance was deficient, and the people were short of quinine, which was looked upon as the one thing that could save life. So scarce was it that in some instances it was sold for upwards of 8*l.* per ounce. The disease was a genuine malarious fever, extremely virulent, attacking its victims and killing them outright, as if by the potency of the poison. Many fell down insensible, never rallied, and died. Whole families were swept away, and it is reported that many houses were left without a single occupant. The most frequent sight that met the eyes was that of the dead being hurried off for burial. There is no difficulty in declaring the cause of the fever. The mountains of this Island of the Indian Ocean form a beautiful plateau in the middle, sloping down to the sea, but leaving a large tract of marshy land between the hill districts and the water. To work the sugar estates a large number of natives of India have been introduced. When first received they are placed upon estates where they are properly housed, fed, and cared for in every way. After serving their "apprenticeship" the majority remain in the island, and those who make or save money purchase small plots of land and build hovels upon them. A number of these dwellings are congregated together, and are let and sublet till they teem with human beings, without the slightest regard for

cleanliness or attempt at drainage. In the town of Port Louis the noisome foulness of the carts which slowly traverse the streets in that hot climate removing the contents of the tubs of the houses may be more easily imagined than described. There is no drainage; and near the town is a graveyard, the stench from which was very perceptible on board ship, at a distance of half a mile. Dr. Blaxall says that on entering the harbour the general exclamation was, "What is it that stinks so?" With a population huddled together on low land, high mountains at the back and the sea in front, a great deal of the land being marshy, swampy, and covered with vegetation, excessive solar heat came on, causing considerable evaporation, and the gases so evolved could not escape, as the north-west wind prevented their going seaward, and the high mountains their passing landward; for these paludal poisons hug the earth, and are too heavy to rise and mix with the purer atmosphere above. The people also were predisposed to sickness by being in an impoverished and depressed state. The sugar crops fell short, owing to a great drought, which caused a diminution of labour. Provisions, which are all imported, became scarce and dear. The heat was intense, almost unprecedented. The usual hurricanes and lightning did not make their appearance. A north-westerly wind scarcely ever changed to the more salubrious south-eastern. In Port Louis, where there was such a vast number of victims, the poison must have been driven by the wind against the high range of mountains immediately at the back, simply to return again, like the back lash of water, and fall upon the fever-stricken town concentrated and intensified. In April, the month of the greatest mortality, several showers fell upon the parched land, and a burning sun coming out immediately afterwards would cause an immense and rapid evaporation, that would probably be the more potent from this quickness, and therefore more deadly and effective in its operation. In that month 200 were dying daily; the whole population of the island is less than that of Birmingham. Such a malarious poison pent up on those low marshy shores, under excessive heat, and among a people ripe for disease, could not fail to do its work. The authorities adopted the most vigorous measures for vanquishing the enemy that had come upon the place. Their utmost efforts were required to prevent many of the poor sufferers from dying literally of starvation. There had been plenty of work and high wages some time before, but no provision was then made for any hour of need. There was not a benefit society or club of any kind. The duties of the relieving committees were, therefore, extremely onerous. The Government can adopt some measures for the prevention of another such fearful visitation of this beautiful island by enforcing sanitary regulations, by preventing overcrowding of houses, and by some other like precautions; but whether it be practicable to drain the marsh land may be a question of some difficulty.—*Times*.

ST. THOMAS IN THE MOOR.—Professor Sands Cox, the founder of the Queen's College and the Queen's Hospital at Birmingham, recently incorporated by Act of Parliament, has conveyed to trustees a valuable site of ground on the Long-mare property, in the parish of King's Norton, Worcestershire, for the erection of a church to the memory of his late father, Edward Townsend Cox. The late Mr. Cox held the appointment of one of the medical officers of the Birmingham Town Infirmary for more than forty years, and discharged the duties of medical officer to the Public Dispensary and at the Barracks, in the absence of the surgeon of the garrison, for a lengthened period. The inhabitants of Balsall-heath owe to the exertions of that late eminent surgeon the church dedicated to St. Paul in that populous district.

ANOMALOUS ACCOUCHEMENT.

Dr. Wm. J. Burge, M.D., of Atchinson, Kansas, reports the following case to the *Leavenworth Medical Herald*:—

Mrs. C., a well-formed, healthy woman, primipara, æt. 20, called me at 8 A.M., April 5th, 1869. I found her in the first stage of labour, and in excellent condition, but as the pains recurred only about once in ten minutes, I anticipated a tedious case, and left the house, promising to return at noon.

At 12 P.M. I found my patient progressing favourably; presentation natural (vertex); os dilatate; pains more frequent, and no apparent reason for much delay. After watching the case until 4 P.M., and discovering no perceptible advance, I went home to dinner—my patient being but a few steps from

my residence. Returning at 5 P.M., everything seemed encouraging; pains at intervals of two minutes, and some progress. Soon after this time the contractions of the uterus became violent, of short duration, and almost incessant. At 9 P.M. the character of the pains continuing as just stated, I commenced giving chloroform, which was very acceptable to the patient, although not pushed to the point of unconsciousness. All night long this state of things continued. I was astonished at the slow advance of the child, as there seemed to be no material impediment. The general condition of the woman exhibited no indication for interference. At 2 A.M. I ruptured the membranes, and at 4 A.M. the head was born. There were two turns of cord around the neck, and it was with some difficulty that I removed them. At the next contraction, with some assistance in the way of traction, the child was born. It was a fine large boy. I thought he was dead, but in a minute or two he showed signs of life, and soon thoroughly revived. I stopped giving chloroform, though the mother had been conscious all the time. Everybody present (the mother not excepted) was delighted. I gave immediately fluid extract *secale cornutum* ʒj, and waited rather more than half an hour. Then as pain came on, I attempted to deliver the placenta by means of gentle traction on the cord with my left hand, while with my right index finger I tried in vain to reach the distal extremity of the cord. With no warrantable amount of force could I succeed. Resting a few moments longer, and finding my patient losing as I thought too much blood, I determined to extract it. On introducing the hand gradually into the uterus, I grasped about half the diameter of the placenta (centrally), and just above this came upon a bundle of cords which passed up through a firm ring, which was about an inch in diameter and perfectly unyielding. Finding it impossible to extract the whole placenta, I concluded to bring away as much as I could: so following down one by one the cords or bundle of vessels above mentioned, till I reached a point where I could break them, I detached them one by one and extracted the principal bulk of the after-birth. The womb contracted in such a manner that there was no further hæmorrhage. It seems to have been a case of complete "encasement" of the placenta, and I suspect this condition obtained during the greater part of the labour, which, to my mind, explains the character of the pains, and the slow progress of the child. I believe the double turn of the cord around the child's neck drew upon the placenta (which was attached to the fundus) in such a manner as to cause violent irregular contractions of the uterus until the vessels of the placenta at the place of constriction were fairly dissected out, forming a mere bundle of cords. I remained by my patient more than an hour, and finding that she continued comfortable and in good condition, went home and lay down to rest. An hour and a half afterwards I was summoned in haste to see her. I found her pallid, pulseless, with blue lips, restless and breathing with difficulty. I grasped the uterus and found it well contracted. Examined instantly and found no flooding. One of the women remarked that she had examined before I came, and she had not bled any. She was perfectly conscious. I commenced feeding her with whiskey. It was no use, for in ten minutes she was dead. No post-mortem could be obtained. I think she died from mere exhaustion, loss of vital energy produced by the protracted labour. No medicine whatever was administered during the progress of this case except the chloroform and ergot as mentioned.

List of names and qualifications that have been erased from the Medical Register by order of the General Medical Council or of a Branch Council, for the reasons assigned in each case:—

JOHN EDWARD PROTHEROE.—Name erased on the 11th of April, 1859, by order of the Branch Council for England, the entry of it having been fraudulently obtained.

JOHN BURTON.—Name erased from the Medical Register on the 13th of June, 1859, by order of the Branch Council for England, the entry of it having been fraudulently or incorrectly made.

JOHN BROATCH.—Name erased, by order of the Branch Council for Scotland, on the 3rd of October, 1859, the entry of it on the Medical Register having been obtained by a false declaration.

RICHARD ORGAS.—Name erased from the Medical Register on the 19th of June, 1850, by order of the General Council, for infamous conduct in a professional respect.

JOHN KEARNEY.—Name erased, by order of the General Council, on the 1st of July, 1861, for infamous conduct in a professional respect.

DANIEL DE LA CHEROIS GOURLEY.—Name erased, by order of the General Council, on the 1st of July, 1861, in consequence of his having been convicted of a misdemeanour.

Introductory Address

DELIVERED AT THE
OPENING OF THE WINTER SESSION

OF THE
UNIVERSITY OF EDINBURGH,

NOVEMBER 2.

By Principal Sir ALEXANDER GRANT.

GENTLEMEN,—In accordance with the custom of this University, I have the honour to open the Session of 1869-70 by addressing to you a few words. And first permit me, as in duty bound, to offer my humble tribute of respect to the memory of my most distinguished predecessor,

SIR DAVID BREWSTER.

Of all the men who have occupied the honourable position of Principal in the University of Edinburgh, probably none had anything like so wide a contemporary reputation as Sir David Brewster. (Applause.) His was a name of more than European celebrity. Fifty-four years ago he obtained the physical prize from the National Institute of France. Forty years ago he was made corresponding member of the same Institute, and subsequently one of the eight foreign associates of that distinguished body. In 1847 he was made Chevalier of the Prussian Order of Merit, and in 1855 Officer of the Legion of Honour. He was made honorary member of the academies, or scientific societies, of St. Petersburg, Berlin, Vienna, Copenhagen, Stockholm, Brussels, Gottingen, Turin, Modena, Philadelphia, New York, and Washington. He held degrees from the Universities of Oxford, Cambridge, Durham, Edinburgh, and Aberdeen; and was for several years Principal of the United College of St. Salvator and St. Leonard, at St. Andrew's. He was the inventor of the lenticular system of dioptric lights, which has since been adopted in all the lighthouses of Great Britain and her colonies. And, turning science to the purposes of amusement and delight, he also invented the kaleidoscope, and the form of the stereoscope which is now in general use.

For his discoveries in the double refraction and polarization of light, he received the Copley Medal, the Rumford Medal, and the Royal Medal from the Royal Society of London.

Sir David Brewster was born eighty-eight years ago, being son of the Rector of the Jedburgh Grammar School, and he entered this University as a student in the year 1793. When, sixty-six years afterwards, he was elected Principal, he was already the Nestor of science, and a more venerable figure it is not easy to imagine. He was the contemporary of Brougham, the friend and constant companion of Walter Scott, and his youthful prime was coeval with the most brilliant period of society in Edinburgh. All through his long life he united literary exposition with severe discovery, and thus was the author not only of scientific treatises, the names of which fill up a folio page in our library catalogue, but also of many pleasing works for the general reader, among which I may especially mention his "Letters on Natural Magic" and his "Memoirs of Sir Isaac Newton." Nothing was more characteristic of him than his urbane cheerfulness in social intercourse. His pleasant and flowing talk was full of interest and instruction, ever playing with "the fairy tales of science," and making him a centre of attraction to young and old. At the same time few men have ever been more persistently laborious than he. His iron constitution enabled him to continue, even to advanced old age, habits of toil which few, even in youth, could rival. The clearness and vigour of his mind were unabated to the last, and even on his death-bed his scientific researches were continued. In death, as in life, he held up to us the example of a Christian philosopher. In the affairs of this University, and more especially in the question of procuring endowments, he took a warm interest, and he ever protested against what he considered the unwise parsimony of all British Governments in the matter of encouraging and rewarding science. His mortal remains were attended to their resting place by a sorrowing procession of his academical colleagues. His grave is on the banks of the Tweed, under the shadow of the ruins of Melrose Abbey. But in looking at it, and in thinking merely of

his name and his achievements, one may well recall the words of Pericles, *Ἀνδρῶν ἐπιφανῶν πᾶσα γῆ τόφος*. Every lighthouse that burns round the shores of the British Empire is a shining witness to the usefulness of Brewster's life. (Applause.)

The learned Principal here entered at great length upon the provisions of the Universities Act, the recommendations of the Commission, and other cognate subjects. Devoting a large portion of his address to graduation in Arts, he approved the proposal to restore the Bachelor's Degree, and entered fully upon the changes he would recommend for that purpose, and the course of education that should qualify for it.

He then turned to the subject of Universities, respecting which he said:—It is the idea of a University to stand at the head of public instruction in the country in two ways: first, as the repository and source of higher learning and science; secondly, as affording by its examinations and degrees the standard at which all the subordinate educational institutions should aim. In many respects our Universities laudably approach the idea of what they ought to be. They are thoroughly national in character, drawing their students from a wide area of the people, and being restricted to no rank or church. Their close connexion with the burgh and parochial schools of the country render them especially qualified for influencing and directing these schools. Well, it may not be this year, nor it may not be next year, but ere long, inevitably, Parliament will rearrange public instruction in Scotland. Whenever that often-promised day shall come, the Legislature will not have done its work if it does not, in addition to extending and settling the primary schools, give them an organization by means of which they shall be qualified for leading up to the secondary schools, and these to the University. Nor is it with parochial and burgh schools alone that the Government must deal. The endowed hospitals of Scotland possess, owing to the well-intentioned liberality of founders during the last two centuries, funds which are acknowledged to be in many cases not fruitfully applied, and which, by a slight change of direction, might be made productive of great benefit to secondary education. Unfortunately, our University of Edinburgh was not understood by those pious and public-spirited citizens. They little knew the wants and capacities of a metropolitan University, else who can doubt that for the foundations of questionable advantage which have half surrounded this city with a ring of palaces, there would have been substituted Colleges for the residence of University students, fellowships, additional professorships, more adequate university buildings, and all the appurtenances of learning and science in which we are now so lamentably deficient? The hospitals may yet, under the powers now given to trustees, be made an assistance to the Universities. But not only the trustees of hospitals, but also the directors of high schools, and the authorities, whoever they may be, who shall carry out the instructions of Parliament in reference to the burgh schools, and all the graded hierarchy of Scottish education, would, I doubt not, be glad to look for guidance to the University degree standard, if it were well and suitably devised.

The University degree standard should both follow and direct the secondary schools. It cannot be kept above what the pupils of those schools can reach within a moderate period of University study. On the other hand, it indicates to the schools a course and method of preparation. For instance, were a scheme like that which I have been sketching out adopted, I conceive that one of its effects would be to encourage the study of some natural science in every secondary school, and at the same time to limit the study of Greek to a selection among the pupils—to those, in short, whose circumstances or natural aptitude qualified them for studying it thoroughly. And the further result would be, that many pupils would be enabled to enter on the studies belonging to what is called the modern side of high schools, without, at the same time, relinquishing all hope of University distinction. And this, I think,

would be an advantage. The University should be free and unrestricted in her hospitality, and should invite all to come who are desirous of following out any of the branches of liberal knowledge.

I have said enough, Gentlemen, to indicate for your consideration a certain line of University policy. Its leading features would be these:—First, to give the University as much connection as possible with the organization of public instruction in this country; second, to open as much as possible the curriculum of study to the free choice of students, so as to meet the wants and circumstances of all classes; third, by the introduction of public triposes and honours, to stimulate more profound attainments in the different and special branches of knowledge. The object would be, as regards the nation, to perform more efficiently a public function; as regards the University itself, to gain first in extensivity, but ultimately in intensity, and, as I before expressed it, by stooping a little to conquer much. Should any of these views meet your approbation, you have now an autonomous constitution, which gives you every facility for discussing them and taking measures to carry them out. And, at the same time, that constitution is sufficiently provided with checks and counter-checks to obviate the possibility that rash innovation or hasty experiment, which would be unseemly in a body like ourselves, could be ventured on. It is now our privilege to be able to obey the exhortation of the Scripture, "That we make a stand upon the ancient way, and then look about us and discover what is the straight and right way, and so walk in it." (Applause.)

Gentlemen students, your several matriculation tickets declare you to be "cives" of the University—citizens, as St. Paul said, "of no mean city." I have therefore thought it right to discuss in your hearing questions of University politics, on which you may some day be invited, as members of the General Council, to give your opinions and your votes. In the meanwhile, I would ask those of you who belong to the Arts faculty to believe that I have no wish to depreciate in your eyes the worth of the degree which is now offered to you. One of the objections brought against it is that it is too difficult. But if so, your satisfaction will be greater if you are able to attain it. Another objection is that it does not afford a sufficiently final, decisive, and public distinction. But University distinctions are, after all, only means to an end, and the most valuable parts of that end you may, with the blessing of God, obtain without them—namely, a cultivated mind, the possession of liberal and useful knowledge and wisdom, which is above all price. (Applause.)

The learned Principal then proceeded to address some advice to the assembled students.

Students of all faculties (he continued), I welcome you to this assembly for the opening of the Session! Some of you are now entering for the first time on University life. It is a manlier, more important, and greater period of your existence than any that you have hitherto gone through. It is a halcyon interval of calm intellectual development, placed between you and the stormy sea of life which lies beyond. And yet this period must be to you one of sustained activity, not without self-denial, for on what you do now will depend to a great extent what you are and how you prosper hereafter. Some of you are not joining us for the first time, but are returning to this as to a familiar scene, to complete what has been begun in former Sessions. But to all alike the beginning of a new Session must be full of freshness, and especially at this time of the year. The autumn of the year in Great Britain is the spring-time of the intellect. At all events, it is the spring-time for those faculties which are concerned with study and the acquisition of learning. When the later autumn has brought back its cold, our wandering inclinations seem, as it were, to return home. Our force is concentrated and thrown inwards, and desires to find expression in mental toil. The study-chamber, the book by the ingle-side, the midnight lamp—these are the objects which now attract our fancy. (Applause.) We feel as if we had strength to

conquer whole realms in the world of knowledge. We take our past acquisitions merely as a starting-point, and, full of resolution, we design to rise "on stepping-stones of our dead selves to higher things." Such is the attitude of mind in which I doubt not that many of you regard this opening Session. And if it be so, then I need not preach to you zeal, but only prudence and method in your studies. And in this respect I have two general pieces of advice which I should like to lay before you. The first is, that you should beware of wasting your powers and impairing the elasticity of your minds by excessive, desultory, or mechanical reading. The real antidote to this danger is to mix, as much as possible, the active and creative with the passive and receptive moods of the mind. It is not necessary to write in order to be creative, though writing, provided that it be not mere mechanical copying, is a great assistance in this respect; but the mind is active and creative so long as it is thoughtfully exercised. And even in reproduction under new forms there is a kind of creation. Therefore I would say, make a point of reproducing to yourselves, in your own words, the main results of the books you read. Probably no man had ever more bright-minded command of a large field of knowledge than the historian Gibbon; and he tells us that his method of reading, which he recommends to young students, was, "after glancing his eye over the design and order of a new book, to suspend the perusal till he had finished the task of self-examination—till he had resolved, in a solitary walk, all that he knew or believed, or had thought on the subject of the whole book, or on some particular chapter. He was then qualified to discern how much the author added to his stock." This appears to me to be a valuable hint, well worth applying to every branch of study, whether literary or scientific. (Applause.)

The second piece of advice which I should wish to offer applies to literature alone. But not the less does it concern all students of the University, for none of you can dispense with literature. If you be not following it in your class-rooms, you all absolutely require it in your leisure hours for refreshment, for delight, for the enriching and liberalising of your minds. And the less leisure you have to give up to varied literature, the more necessary will it be that you should listen to my maxim, which is contained in three short words, "Read great books." The intellect grows on what it feeds on, especially while a man is "im Werden," as Goethe expressed it—that is, while the mind and character are in process of formation. Ten years hence it will make comparatively little difference to you whether or not you now read all the newspapers, reviews, magazines, exciting novels, and other ephemeral productions of the day, but it will make the greatest difference to you whether or not you have accustomed yourselves to know and love great books. By imbuing your minds with great books now, you will gain a vantage-ground for dealing hereafter with the thoughts of your age. You will gain reverence and gravity, and a certain refined nobility of spirit. . . . And yet great books are not necessarily old books, and certainly they are not of necessity hard or uninteresting. There are great novels, biographies, and travels, as well as great poems, histories, and philosophies. The test of their greatness is their permanence, that they can be re-read from age to age. It has been said that out of the innumerable printed productions of the human race, there are, at least, a hundred great books in different languages—that is to say, the works of a hundred great authors. These hundred masterpieces, if we take that number, contain the highest and happiest efforts of the human mind, under the various phases of the history of civilization. To know these books goes far towards the sum of liberal education. And I think that no better expedient could be adopted by a student during his University career than to draw up for himself, after due inquiry and consultation, a list of the hundred greatest authors that the world has seen, and to propose it to himself as an object, gradually as his leisure may serve during succeeding years, to make himself acquainted and familiar with all of these. . . .

In conclusion, my colleagues of the University of Edinburgh, I must not forget that though this is my first occasion of addressing you, yet I have been a whole year among you, during which time I have received from you the most cordial welcome, the kindest indulgence, and the most generous support. For these I beg you now to accept my grateful thanks.

A year is but a short period in the history of a University, but this past year has been full of academical changes and events. During that space I have witnessed the election of a new Chancellor and of a new Rector. Both these elections connect us with the Supreme Court of Judicature, and give weight and dignity to our counsels. I have seen the election of the first Parliamentary representative of the University, in the person of Dr. Lyon Playfair, who has already, by the exercise of his political abilities in the House of Commons, conferred honour upon us, as he formerly did, as professor of chemistry, by his wide scientific and technological reputation. I have seen two new appointments of members of the University Court, and the election of three curators. I have listened to the inaugural lectures of a new professor of moral philosophy, of a new professor of biblical criticism, and of the first professor in the new chair of engineering. This additional chair is due to the enlightened munificence of our benefactor, Sir David Baxter. (Applause.) From its foundation, if it be connected, as I trust it may, with a well-devised scheme for degrees in engineering, it is not impossible that there may result the development of a great scientific school of the greatest usefulness to the country. During the past year I have seen the appointment of new professors in the chairs of chemistry, of clinical surgery, and of general pathology, in the persons of Dr. Crum Brown, Mr. Lister, and Dr. Sanders, all of them men of high professional and scientific reputation. (Applause.) I have seen measures set on foot—as yet only of a tentative and initiatory character, but still evincing the public spirit, good feeling, and enlightenment of the citizens of Edinburgh—measures for the material enlargement of the University borders, and for providing us with additional academical buildings. Finally, I have seen the University, indirectly, by the zeal and energy of some of its most eminent professors, aiding in the promotion of the higher education of women. (Loud cheers and hisses.) And of late I have seen the beginning of more direct steps to be taken by the University towards the same desirable and proper end. In short, the past year has been, on the whole, one not only of organic efficiency, but also of vital growth, giving good hope for the future; for Universities are not like individual men, who have each only one body allotted to them, so that when that body is worn out their earthly work is over. A University is like a soul, which can always take to itself new bodies—that is to say, new forms and institutions better suited to the times—and thus may be ever beginning afresh, under more favourable circumstances, the struggle for existence.

Report of the Inaugural Address

DELIVERED AT THE

OPENING OF THE WINTER SESSION

OF THE

UNITED COLLEGE, ST. ANDREWS,

NOVEMBER 2nd,

By Principal SHAIRP.

THE learned Principal, who was received with great applause, commenced his inaugural address by a remark on the sadness which changes that are daily taking place around us are calculated to produce. He touchingly alluded to the loss which the United College had sustained about this time last year in the death of the late Principal Forbes. He then proceeded to say that he would not dwell upon his predecessor's merits as an investigator of science, which duty had been done by others more competent than himself, but would speak of

his career chiefly as an illustration of that self-education which every man of ability can carry out for himself. The son of a Scottish Baronet of good family, of Jacobite principles, James David Forbes manifested from his earliest days a strong predilection for the study of physical science, foreshadowing in some degree the reputation he was destined to attain in after years. The principal superintendent of his studies in boyhood was a governess, and as his father wished him to enter the Scottish Bar, his devotion to scientific pursuits was necessarily kept secret. Previous to entering upon his college studies, he began a private meteorological journal, the entries in which manifest those powers of patient observation which characterise the true votary of science. In the year 1825 he entered the University of Edinburgh. At the close of this, his first session, he entered into an anonymous correspondence with Sir David, then Mr. Brewster, at that time editor of the *Edinburgh Philosophical Journal*, under the signature of *Delta*, upon scientific subjects. Such was the modesty of young Forbes, that for a long time Brewster was unable to discover who his young correspondent really was. A year spent in Italy, although it interrupted his college curriculum, was no interruption to his scientific pursuits. The learned Principal alluded in graceful language to the emotions which must have been evoked in the mind of young Forbes, when he visited those localities, so dear to every classical scholar—as he mused by the tomb of Virgil or gazed admiringly at the Bay of Naples. He continued to maintain his correspondence under the mask of anonymity until 1828, when it was dropped. About this time Sir David wrote a letter to young Forbes, remarking that, with the exception of himself and another, he knew no young man who was likely to extend the boundaries of science. It was an almost unnecessary corollary to his previous career that, in the class of Natural Philosophy, under Sir John Leslie, he carried off the highest honours from all competitors, although he had not at that time reached his twentieth year. In deference to the wishes of his father, he attended the usual classes necessary to qualify for passing at the Scottish Bar, obtaining his gown in 1830. It was in the year 1832, when political feeling ran so very high, that he was appointed by the Town Council of Edinburgh, and by a large majority, at the age of twenty-three, to the chair of Natural Philosophy, rendered vacant by the death of his former teacher, Sir John Leslie. It is worthy of note that although his opponent on this occasion was the illustrious Sir David Brewster, yet no interruption to the friendship which existed between these two eminent men resulted from their rivalry on this occasion. For seven-and-twenty years Professor Forbes adorned the chair to which he had been advanced at so early an age, by the admirable character of his teaching, evoking the spirit of science in the minds of those who enjoyed the advantage of his prelections. The Principal alluded very slightly to his published works in the department of physical science, which are so familiar to our readers that it is unnecessary here to specify them. The learned Principal, after referring to the severe physical ailments of Professor Forbes, induced by his exertions in the interests of physical science among the glaciers of the Swiss Alps and elsewhere, went on to speak of his career as Principal in the United College at St. Andrews, to which office he was appointed in 1859, on the removal of Sir David Brewster to the Principalship of the University of Edinburgh. Principal Shairp, speaking of the enthusiasm shown by the deceased Principal, said that his office was no sinecure, and that his colleagues could testify to the untiring interest which he exhibited in everything that could promote the advantage of the University. Amongst other measures for the benefit of the College, he took a most prominent and active part in the establishment of the College Hall, the last act of his public life being the laying of the foundation-stone of the new building in April 1867. The learned Principal con-

cluded a long, interesting, and minute account of the career of his predecessor, by briefly indicating the lessons which such a career is calculated to teach the youthful academic mind. After the names of the successful competitors in the recent bursary examination had been announced, the proceedings terminated with the pronouncing of the benediction in Latin by the Principal. The address was listened to with great attention, and was frequently applauded.

Original Communications.

CASE OF SNAKE-BITE, COMPLICATED WITH A PECULIAR ARTIFICIAL CONSTRICTION OF THE PENIS.*

By MR. JULES LE CARPENTIER,
Assistant-Surgeon, U.S. Army.

PRIVATE W. Robinson, of B Company 3rd U.S. Cavalry, a re-enlisted man, had always been remarked by the singularity of his acts, and had been known in his Company as a snake-charmer, having handled many a time rattlesnakes or others without being injured.

On the morning of the 13th July, 1869, Robinson was detailed on guard with the herd of Fort Cummings, N.M., when, in presence of other herders, he succeeded in catching a rattlesnake, and tried once more to prove his power upon these monsters. He succeeded, and, the performance being over, the snake was killed, when, at the same moment, he took sight of another snake of the same class, and tried to charm this as he had done the other one. But there his power failed, and he was bitten at once into the middle finger of the left hand, and he applied immediately for relief, complaining only of a little smarting, that he compared to the pain following the injury caused by the sting of a bee or a wasp.

A ligature was applied above the wound; the two injuries made by the fangs were enlarged with the bistoury; ammonia and actual cautery applied, and the man ordered to take whiskey in large doses frequently repeated. Admitted into hospital, of course. The constitution of the patient being broken down and poor, I had doubts from the beginning as to his recovery, being inclined to think of a fatal issue.

July 13.—Vomitings soon came on, but were stopped without trouble; swelling of the hand and forearm increased gradually, showing the very particular lividity and yellowish tint following the bites of poisonous snakes.

Treatment.—Blister to the bitten finger; tincture of iodine; roller bandage; whiskey, ℥ij. every half hour, until ebriety; beef-tea; opium, gr. ij. at night.

Pulse very much reduced at first; gained gradually under the influence of stimulants.

14th.—The patient has slept well, and does not complain except of numbness of his arm; swelling has gone up as far as the shoulder-joint; blood, very fluid, is incessantly running from the wounds.

Dressing of carbolic acid and cerate liniment applied to the arm; acetate of lead solution; tinctura ferri chloridi, gtt. xij., four times a day.

15th.—General condition good; swelling somewhat increased, but not so much lividity, with the exception of the yellow hue, which has increased.

16th.—Ditto: pains in the neck on the side of the affected limb.

20th.—Gangrene destroys the extremity of the bitten finger; general condition good.

The man complains of a *trick* played on him, he says, by some unknown party or parties, and upon showing his genitals an iron ring of a very small diameter (6-8ths

* Forwarded by Dr. Moore, "King's Professor of the Practice of Medicine," School of Physic, Ireland.

of an inch) is discovered imbedded in the soft tissues of the penis, constricting it to such a degree as to have produced an enormous enlargement of the parts.

Upon inquiries, it seems probable that the ring had been kept on the parts very long, and as a preservative of chastity; but the swelling having come on under the influence of the snake's venom, and the patient having much difficulty to pass his water, he was obliged to complain. The ring was filed off with some trouble.

July 22nd.—Condition good; swelling rapidly decreasing; no progress of the gangrene.

28th.—Improves very much, and I resolve to disarticulate the bitten finger to the metacarpian.

30th.—Amputation of the finger. Anæsthesia readily obtained, but hardly any appearance of the second stage observed in the administration of anæsthetics.

Two ligatures and sutures, simple dressing, irrigation, anodynes.

August 1st.—The patient has been very well since the operation. I was called early in the morning, the patient having been observed to sink. I found him with stertorous respiration, pulse weak and slow. Partly conscious only.

Brandy and bromide of potassium; electricity.

Died, 11:30 a.m., without a struggle.

Necropsy, one hour after death.—General softening of the tissues, particularly on the affected side. Blood black and very fluid, not coagulable. Ventricles of the brain filled up with a large amount of serosity. Brain somewhat congested.

Lungs healthy, with the exception of a few crude tubercles of recent formation in the left lung.

Heart.—Right ventricle filled up with dark blood, non-coagulated.

Liver healthy; gall-bladder very much distended with bile.

Kidneys healthy.

Intestines presenting a few livid patches on the outside.

Fort Cummings, New Mexico:

August, 1869.

CASES IN GENERAL PRACTICE.

By J. H. WATSON, M.R.C.S.

I.—A BOY, æt. ten, was brought to my surgery one evening last week, who declared he had swallowed, *all at once, six* halfpenny pieces! The fact was corroborated by his mother, and proved, to my satisfaction, the following morning, he having voided them, *all at once*, about ten o'clock, each coin having the usual unmistakable appearance of having been subjected to the action of sulphuretted hydrogen. I, of course, in the first instance, caused him to swallow half an ounce of castor-oil.

It appears the lad was playing "shops" with younger children, and when he swallowed the coins he was lying on his back on the floor, with his feet raised on a stool, and in attempting to change his position the halfpence suddenly and altogether passed into the stomach.

II.—I was called in to see a child (male), æt. two years and a half, a few mornings since, who I found suffused with a scarlet flush; skin, of course, hot and dry. There was considerable dyspnoea—in fact, semi-orthopnoea; great restlessness; and total loss of appetite. Besides this, there was considerable crepitation observed of both lungs.

Now comes—to me and others—a matter of some astonishment: in *twelve hours* all these symptoms had disappeared; the child had become quite pale, quiet, and the difficulty of breathing removed, succeeded by a rather irritable cough.

Now, as scarlatina is prevalent, did my prompt treatment arrest a premeditated attack of this enemy? I say *propiti*, because I ordered, contrary to custom, the medicine to be given *every half hour*, which the mother continued for

twelve hours, thus giving twenty-four doses of a mixture composed of—

Antim. tart.
Vin. ipecac.
Magn. sulph.
Pot. nitr.
Syr. erocis.
Sp. æth.-nit.
Ol. menth. virid.

Hospital Reports.

CLINICAL RECORDS FROM THE DUBLIN HOSPITALS.

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.

Case of Hydrophobia.

A STRONG, healthy man, æt. 35 years, was admitted into the Meath Hospital, under the care of Mr. White, on Wednesday, October 27th, suffering from symptoms which were at once perceived to be those of hydrophobia. He had been bitten by a dog, said to be mad, about four months before; but, although "feeling as if something was hanging over him," had suffered no actual illness from the time of his accident until the Monday before his admission, on the morning of which day he found himself unable to swallow his tea, every effort to do so causing, as he said, "a stoppage of his breath." He vehemently, and with the peculiar horror, denied that the bite of the dog was in any way connected with the cause of his illness.

After his admission on Wednesday morning his inability to swallow either solid or liquid food increased with terrible rapidity; and in the afternoon, when water was given him at his own request, the effort to drink it caused fearfully agonising spasms.

The subcutaneous injection of atropine was determined upon, and 1-30th, 1-20th, and again 1-20th of a grain of the drug was introduced during the day, considerable rest and ease resulting from each dose.

On Thursday morning he was much worse. The characteristic 'horror' of the disease had now become fully developed—he attempted to leave the hospital—and it became necessary to place him in a straight waistcoat and strap him in bed. About noon he became quite delirious, and continued so until about 11 p.m., when he died. The atropine was, on the second day, introduced in three quantities of, respectively, 1-15th, 1-15th, and 1-12th of a grain, and on each occasion with some temporary benefit, less marked, however, than that resulting from the earlier administrations. Nutrient enemata were also thrown into the intestine.

A *post-mortem* examination was made on Friday, and revealed extensive congestion of the lungs, brain, and every part of the mucous surfaces; the larynx and pharynx being congested to the last degree, and the vocal cords, apparently, almost in a state of gangrene.

We believe that Mr. White purposes publishing full particulars of this most interesting case.

CURE OF ACUTE ORCHITIS IN TWENTY-FOUR HOURS.

F. Jordan (*British Med. Journal*) thus describes his treatment of a case of acute orchitis: "A man age thirty had intense pain, intolerable tenderness, and great swelling and induration in both testicles, and could not stand upright. The scrotum was covered with a solution of nitrate of silver (two drachms to the ounce), a stripe of vesication was established over the upper halves of both femoral arteries by means of liniment of iod., and the testicles supported by cotton wool. He was well in twenty-four hours.

Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

MONDAY, NOV. 1, 1869.

Mr. PETER MARSHALL, President.

Mr. JABEZ HOGG brought before the Society a young woman upon whom he had operated for ectropium. The operation was a modification of Driffenbach's. He made a semi-lunar incision through the skin and dense structures below the everted lid, and continued to deepen the cut till it reached the conjunctival sac. He then seized a fold of the uninjured conjunctiva with a pair of toothed forceps, and passed two stitches through it at short intervals. On drawing this down, the lid became immediately inverted; the ends of the silk were then drawn upwards, and secured to the superior orbital ridge with plaister; a firm pad and bandage were applied to keep the parts adjusted. The open wound made by the knife was left to granulate. Adhesions quickly formed between the conjunctiva and the lips of the wound, and in ten days she left the hospital greatly improved, and with the epiphora (which she also suffered from) quite cured.

Dr. JEPHSON read notes of a very interesting case of cancerous deposit in posterior mediastinum, with effusion into the left pleural cavity. An animated discussion followed, in which the President, Drs. Hare, Routh, Symes, Thompson, and Day took part.

Dr. SEMPLE read a paper on the "Prognosis of Heart Disease." The author adverted, in the first place, to the general impression long entertained by the public and Profession as to the necessarily fatal character of heart disease. The invention of the stethoscope and the advances made in pathology rather increased than diminished this impression, for the practice of auscultation revealed the existence of cardiac mischief in many cases where it was quite unexpected not only by the medical men, but by the patients themselves. Dr. Semple questioned the propriety of informing the patients of the existence of heart disease in all cases where some abnormal bruit is detected in the cardiac region, not only on account of its disturbing the mind of the patient, but experience proves that both acute and chronic diseases of the heart are far less fatal than is generally supposed. He took some credit to himself for having been one of the first to point out that diseases of the heart, even of a decidedly marked character, and involving the valves, were not so dangerous to life as was formerly supposed, and that persons may and do live to an advanced age while labouring under such affections. In 1856 he presented a paper to the Medical Society of London on this subject, and he showed, from cases that had come under his own observation, that serious disease of the valves was compatible with longevity, and even with a moderate enjoyment of life. These views had been confirmed by all subsequent experience, and are now generally adopted. In reference to life assurance, the author considered these opinions ought to, and now do, have weight. Dr. Semple recorded a very recent case of a young lady suffering from valvular disease, following repeated attacks of acute rheumatism, and although the heart is permanently altered, the patient is now enjoying good health, has lately married, has had a child, and has taken a voyage to the Antipodes.

A very interesting discussion followed the reading of this paper, in which Drs. Leared, Thompson, Hare, Jephson, and Broadbent joined.

ANTHROPOLOGICAL SOCIETY OF LONDON.

At the evening meeting held on the 2nd inst., Dr. BEIGEL, V.P., in the chair, the following new members were announced:—

Fellows.—Captain G. J. D. Heath; Dr. Samuel E. Maunsell, R.A.; Thomas Milne, Esq., M.D.; E. W. Martin, Esq.; Robert Watt, Esq.; Horace Swete, Esq., M.D.; Lieut. Wm. Francklyne; and Wm. Pepper, Esq.

Hon. Fellow.—M. Le Baron d'Omalius d'Halley.

Corresponding Member.—Professor Dr. August Hirsch.

Mr. PIKE read a paper "On the Methods of Anthropological Research." It was useless to speak of methods of research without some previous definition of the objects of research. It should be remembered that anthropologists wished to render useful in combination a number of studies which

might appear useless in themselves. Anthropology was the most practical and the most comprehensive of all the sciences; its great end was the discovery of the laws of human life, upon which must eventually be founded all education, all government, all colonisation, all social arrangements, all principles of right and wrong—so far as those principles might be independent of religion. In the attempt to discover these laws the same line of march must be followed which had led to success in other branches of inquiry. The three things needful were observation, generalisation, and verification. The real difficulty in anthropology was to know what to observe, and how to verify. He believed that the science could advance only by a double method of observation—the observation of mankind individually and in masses, and that the conclusions suggested by the observation of masses, races, or nations must be verified by the observation of individuals, and *vice versa*. For this reason he thought it was a mistake to speak of ethnology as a science, as it consisted only of a series of disjointed observations without conclusions, and without the means of verifying conclusions if made. Mr. Pike then reviewed at considerable length the ramifications of anthropology into anatomy, physiology, psychology, and the various subdivisions of those studies, suggesting that all kinds of unsuspected correlations were yet to be discovered by a rigorous application of a scientific method. The relations of mind to body, of faculty to faculty, of one part of the body to another, were still removed but little from the realms of mystery from which only anthropology could thoroughly drag them away. Mr. Pike concluded by describing anthropology in one of its aspects as the only kind of philanthropy which could be of service to mankind—philanthropy founded upon science.

Summary of Science.

By C. R. C. TICHBORNE, F.C.S., M.R.I.A., ETC.

[The Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

ACTION OF BOILING FLUIDS ON GLASS.

Emerling says that Bohemian glass stands acids better than those made with soda. The Berlin porcelain ware is only perceptibly acted upon by alkalis. The action of all boiling liquids upon glass vessels is proportionate to the duration of the boiling, and proportionate to the surface exposed. The action decreases with decrease of temperature alkalis; even, in dilute solutions, attach glass very strongly, acids generally act even less than pure water—with the exception of sulphuric acid. Among the salts those act most energetically that form insoluble salts of lime—viz., sulphate and phosphate of soda, carbonate of soda, and oxalate of lime. Such salts as form in water readily soluble salts with lime, for instance, chloride of ammonium act less strongly than pure water, and with a greater degree of concentration of such salts the action decreases.

NEW REACTIONS TO DISTINGUISH BETWEEN PHENOL (CARBOLIC ACID) AND CREOSOTE.

Mr. Crump has communicated the following reaction to the *Chemical News*:—If fragments of caustic potash be added to a solution of phenol in chloroform, the potash becomes covered with a rose-coloured coat, and when potash has been added, equal in quantity to about three times the weight of the phenol, the final result is a brown amorphous mass, soluble in alkaline liquids, and precipitated therefrom by acids. It seems to be a mixture of two substances. The second of these substances when treated with tetrachloride of carbon gives no reaction in the cold, but at 100° C. the liquid assumes the colour of rosolic acid. When creosote from wood-tar is treated with chloroform and caustic potash, a reaction takes place very similar to that with phenol, but the product of the reaction is quite different, forming with sulphuric acid a deep crimson solution, from which a dingy green precipitate is thrown down by dilution. Moreover, the substance produced from phenol in alkaline solutions colours silk or wool brown, while those from creosote have no colouring power at all.

NITROPHENIC ACID AS A DISINFECTANT.

Mr. J. Hirsch, in the *Pharmacist* (published by the Chicago College of Pharmacy), states that nitrophenic acid is a more powerful disinfectant than carbolic acid. The nitrophenic

acid seems not only to coagulate albumin readily, but in a dilution of 1-100,000 it produces a loose cloudy coagulum, which carbolic acid only shows in a solution of ten times greater concentration. The experiments with putrid blood were most successful. Binitrophenic acid and the preparation used was prepared from crude carbolic acid. It possessed the aromatic pleasant odour, reminding one of nitro-benzole, and due probably to the presence of that substance in minute quantity. As the author remarks, this pleasant odour is certainly a valuable property of a disinfectant, and presents advantages over carbolic acid in this respect. Mr. Hirsh says he does not hesitate to assume a like superiority for the other nitro-compounds, e.g., the trinitrophenic acid, or picric acid, the value of which is well known in malarious fevers. The chlorophenic and sulphophenic acid may by analogy be expected to act with more energy than carbolic acid.

SUGGESTIONS IN PHARMACY.

The following suggestions in connection with Pharmacy have appeared in the *French and American Journal of Pharmacy*. They seem to have some considerable value.

TINCT. OPII CAMPHORATA.

Mr. J. Wharton suggests a formula for the preparation by which the process of maceration is avoided. The preparation of this tincture by Mr. Wharton's formula is in regard to time merely a matter of mixing and filtering, it has also the advantage of uniformity in appearance. The author mixes laudanum with the other ingredient in a proportion calculated to agree with the U. S. formula. The oil of aniseeds he rubs up with a little carbonate of magnesia.

FLUID EXTRACTS.

Mr. Campbell proposes a method, the object in view consists in adopting a uniform grade of fineness of powder for all substances. He recommends long maceration and the use of glycerine, and percolates the whole quantity at once, thereby avoiding reservation, and evaporation, he thus simplifies the process very much. The author had been surprised at the results obtained from the use of glycerine as a solvent of the active principle of the drugs. A fluid extract should be a concentrated solution, embodying all the sensible and remedial properties of a drug or drugs, and should represent the drug as it is thrown into the hands of the pharmacist from nature. Therefore no heat is used in making these extracts.

NITROUS ETHER.

Sweet spirits of nitre as generally obtained, is more or less strongly acid, reddening litmus paper, and liberating iodine from iodide of potassium. Mr. Ebert in the same journal recommends the use of animal and vegetable charcoal. Two ounces of purified animal charcoal shaken up with one pint of nitrous ether, and left to stand eight or twelve hours, will be found to be quite free from acid on filtering.

A really good and practical process for sweet spirits of nitre has yet to be discovered, although that in the British Pharmacopœia is, perhaps, the best we possess.

THE MEMORIAL OF THE TEN THOUSAND.

LAST Thursday evening a number of gentlemen interested in the subject of medical reform dined together at the Medical Club. Dr. BELL FLETCHER, of Birmingham, occupied the chair, and introduced the subject of the memorial on medical reform, signed by nearly 10,000 practitioners, that is to be presented to the Home Secretary during the present month.*

* MEMORIAL.—The undersigned members of the Medical Profession respectfully submit to the General Council of Medical Education and Registration of the United Kingdom, the necessity of obtaining an Act of Parliament to amend the Medical Act of 1858, and the Acts subsequently passed with a view to amend it. The Act of 1858 affirms that "it is expedient that persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners." The experience of the past ten years has proved that the Act is practically inoperative as a guide to the public in distinguishing legally qualified members of the medical profession. A large number of men are practising medicine and surgery in different parts of the country, not only without any legal qualification, but without having undergone any regular course of medical education. In some places men are practising under fictitious names, assuming the title of doctor, and obtaining considerable sums of money from weak persons by intimidation and extortion. The Medical Act of 1858 is practically inoperative in restraining these offenders. It is capable of proof that some legally qualified men have lent their names to persons without qualification, to

Such a movement as that originated by the earnest medical reformers of Birmingham deserves the most attentive consideration of both the Profession and the public, and we think the members of the Medical Club have done well to meet and discuss its clauses.

The only regret felt must be that the shortness of the notice given of the meeting prevented many from being present. It is to be hoped that this is but the commencement of a series of meetings of the kind; for the Medical Club, numbering gentlemen of all shades of opinion as its members, is admirably adapted for the friendly discussion of everything affecting the Profession.

Having read the memorial, Dr. BELL FLETCHER said:—Gentlemen,—I do not doubt that we all look forward to the approaching Parliamentary Session as one likely to exert a very decided influence on our Profession. For the first time in our history the Government and the Parliament will have, in the memorial entrusted to me for presentation, a clear statement of the views of a very large proportion of the qualified practitioners in England, Scotland, and Ireland. The memorial is certainly not an exhaustive statement of our wants, but it is a clear and moderate expression of general principles, which, once conceded by the Legislature, will in the course of a few years enable us to work out the great object of consolidating the Medical Profession in the British Empire as *one* body of men competently educated in the science and practice of medicine, as *one* science, *one* art. When we are united on the common basis of education, and with one tie of professional brotherhood, we shall have no difficulty in making good our position amongst other professions and great bodies of men, to none of which have we ever yielded for unselfish devotion to the great cause of social well-being and advancement. If the memorial be little more than a declaration of principles, I hope the corporations will not imagine that the great body of memorialists, nearly 10,000 in number, have not a very clear opinion on the altered relations in which the corporations and the Profession must henceforward stand to each other. Speaking personally, and for those who have directly acted with me in this matter, we have no desire to attack the medical corporations, we would willingly only remember the bright pages of their histories; but we sincerely hope they will fathom the vast moral power of the memorial, and resolve to act with, not against, the 10,000 men who, from every corner of the three kingdoms, have come forward to affirm that we want professional solidarity, as against collegiate divisions, and we crave the influence and power in the State which can only be inferred

enable them to practise medicine and surgery without incurring liability to prosecution. Such a proceeding is regarded as a fraud on the public and the profession; and it is suggested that in any future Bill greater powers be given to the General Medical Council to remove from the Register, and deprive of their professional rights qualified men who shall aid and abet illegal practitioners. The present state of the law touching certificates of death, greatly favours the successful practice of secret poisoning and infanticide. It is suggested that the certificate of a legally qualified member of the medical Profession in the absence of a coroner's order, shall be indispensable as a preliminary to every burial. The Medical Act of 1858 purports to constitute the General Medical Council for the purpose of regulating medical education and registration throughout the United Kingdom: but composed as the Council is mainly, of the members of the medical corporations who grant licenses to practise, the control of the system of medical education has proved to be very imperfect. The undersigned are of opinion that the system of medical education should be revised, so as to ensure the possession of a thoroughly scientific and practical acquaintance with medicine and surgery on the part of persons applying for the legal qualification. To this end it is held to be necessary to substitute for the present system of examination, and for the many forms of licence to practise now granted, one high and uniform standard of examination, and one legal qualification. The practical part of the course of professional study stands in special need of improvement, and the undersigned would gladly see the regulations made stringent, to ensure the attendance of students on a thorough course of practical study in hospitals; but in the event of any student engaging in private practice on his own responsibility before he is legally qualified, it is suggested that he forfeit the year or years as a student, during which he has so practised. It is respectfully, but very earnestly, submitted that the influence and power for good of the General Medical Council would be greatly extended with the profession and the public if provision were made in a new Act of Parliament for the representation on the Council of the general body of practitioners of medicine and surgery, who are now for the most part deprived of any professional franchise. In any future Act of Parliament it is suggested that provision be made for instituting prosecutions under it by a public professor, or other public functionary, on behalf of the General Medical Council, instead of leaving the voluntary enforcement of the law to individuals. The undersigned desire to obtain no privileges for the profession without giving the public commensurate advantages, and they submit that an Act of Parliament so framed as to raise the standard of professional efficiency, to protect life and prevent the obtaining of money under false pretences, is an Act as much needed in the general interest of the community, as for the welfare and honour of the medical profession.

by knowledge, and by a professional organization at once broad and enlightened, wise and unselfish, safe and progressive. Speaking in this social home of a large number of eminent London men, I venture to throw out as a hint that a mistake is often made in underrating the character and intelligence, the social power and substantial trustworthiness of provincial men. I do say that one great evil of the system which has hitherto prevailed in the medical corporations has been the virtual disfranchisement of all non-London or non-collegiate men—a practice at once narrow and illiberal, neither defensible on grounds of equity nor sound policy. As independent thinkers, and plucky and determined writers, the provincial men claim consideration; and I can pledge myself that those who have worked with me in this matter, and the many thousands of prominent men who have responded to our call, will be found good soldiers in the contest, from which, I trust, we shall none of us retreat until we have achieved "Professional Unity."

Dr. LORY MARSH explained that the object of the meeting was to elicit the opinions of those present on any of the points brought forward by the able and disinterested Chairman, who had come from Birmingham on purpose to preside. He might say that if one person was more responsible than another for such a meeting, it was Dr. Prosser James, as that gentleman had first suggested that such reunions might be both agreeable and useful. He therefore asked him to join in the discussion.

Dr. PROSSER JAMES acknowledged that he had made the suggestion, and in consequence of that had felt bound to be present to support the Chairman as far as he could. A memorial signed by so large a number needed no speech in support of it. He might, however, venture to differ from the Chairman as to one observation. Speaking for a large number he could say they did not at all underrate their provincial brethren. For much of the real respectability that characterised the profession, for genuine earnestness in any good cause once begun, frequently for the initiation of one, it was necessary to go to the provinces. For proof of this he need only instance the men of Birmingham, and conspicuous amongst them the worthy and indefatigable Chairman himself. The memorial opened up a number of questions on which opinions would be sure to differ, and on which for the present he would prefer to be a listener.

Dr. SEATON had many years ago directed his attention to medical reform, and he was of opinion now, as he had been then, that the Profession should be divided into two classes; the general and consultant practitioner. He urged that it would be well for the former to be distinguished as *members*, the latter as *fellows*, of the body medical; that it should be incumbent on all to spend several years in the former rank before being promoted to the latter. He would have but one examination, that for membership. The fellowship should be attained by registering and paying a fee, after a certain number of years, and then the consulting fee should be imperative.

Dr. CHAPMAN thought the less control the State had over the Profession the better, especially as regarded the education of its members. If the Profession sought to obtain State protection, the public had a right to require that none but thoroughly educated men should be able to obtain a diploma to practise. Sound and efficient medical teaching was the chief thing required to ensure good practitioners, and as to how and where this could best be obtained might safely be left to the great body of the Profession to determine. All the public had to consider was, that the examinations should be of such a searching character as to ensure none but competent men being admitted to practise.

Dr. O'CONNOR strongly supported the view that members and licentiates of the corporations should elect the representatives in the Medical Council, and he hoped Sir J. Gray, M.P. for Kilkenny, who had for many years occupied himself with medical reform, and had now a motion on the books of the House of Commons, would favour the meeting with his views.

Sir JOHN GRAY said he was more anxious to hear the views of others than to put forward his own. He was seeking information, and, while deeming it right to protect the people from ignorant unqualified men, he would certainly protect the well-educated, qualified practitioner. He would do this in the interests of Her Majesty's subjects. Soldiers were costly to the country, each man cost £100 sterling, and extra care was, therefore, taken that only skilled men should practise upon those men. Was it not possible that something of the same kind might be done for the civil population, some extra test of clinical knowledge imposed upon the 10,000

memorialists desired, "one high and uniform standard of examination, and one legal qualification to practise?" He thought this might perhaps be accomplished without overturning the existing institutions, which would still have the training and testing of men up to the last step. He would like there to be a rivalry as to which body would turn out the best men, rather than a competition downwards of qualifications to practise. The corporations had done much good, there was still good in them. Why, then, destroy them? He would rather see them rivalling each other in the manner at which he had hinted. He was glad he had come to the meeting, for he wished to learn all he could. Though he had long since left the Profession for another sphere, he had their interests at heart, and would be glad to promote them by every means in his power. Sir John resumed his seat amidst great applause.

Several others joined in the discussion that followed, which was brought to a conclusion by a vote of thanks to the Chairman, and to Dr. Lory Marsh, both of which propositions were carried by acclamation. It only remains to add that in returning thanks, Dr. Marsh remarked that there were numerous questions of great interest to medical men as such, which would come before Parliament in the ensuing Session. As examples, he named vaccination, contagious diseases, and other propositions relating to public health. He thought that such a friendly discussion as had taken place this evening likely to be productive of good. The Club numbered many of their army and navy brethren in its list of members, and they, he knew, would be glad to join in such discussions. It was, therefore, easy to see that frequent reunions of this kind might prove beneficial.

This suggestion was very warmly received, so that if other such reunions be held, they are sure to be successful.

SCOTLAND.

THE suggestion thrown out by Sir Alexander Grant, in his address at the opening of the University of Edinburgh, that the number of curators, or patrons of the University appointments, "should be augmented by the addition of two additional curators, not to be chosen by either of the two present electing bodies," must commend itself to all who are familiar with the constitution and working of the Curatorial Court. Consisting of seven members, three appointed by the Crown and four by the Town Council of Edinburgh, the "Board presents the appearance of a house divided against itself," with, however, the comfortable assurance to one party, that in the domestic broil, if they can only preserve unity among themselves, victory on their side is certain. In reality, the representatives from the Town Council, by a majority of one over the other members of the Board, have, by a little combination, the gift of the University livings in their own hands; and if we take into consideration the various elements adduced by Sir Alexander Grant, as tending to interfere with the right administration of this privilege, the necessity of neutralizing this power becomes apparent. The same mischievous element, or incompatibility, which deprived the Town Council of the patronage of the University, exists in the Court of Curators. It is, indeed, true, that as yet the manner in which the patronage of our medical chairs has been exercised by the Board has been perfectly satisfactory, and the Profession is fully alive also to the inestimable benefits which have accrued to the medical faculty of the University by the judicious selection of such men as Professors Spence, Turner, Crum Brown, and Sanders, to fill their respective chairs. But this circumstance does not in the slightest degree affect the general question; it is but the accident of an accident, the result of a combination of circumstances which may never occur again, and a basis, therefore, upon which no solid argument can be raised. Such an argument,

indeed, might, with a far greater show of reason, have been used as a plea for retaining the patronage in the hands of the Town Council. They could point to a long series of preeminently successful appointments;—they could plead that the largeness of the constituency in itself helped to secure to the candidates an impartial consideration of their claims, from the probability of its including within its number a fair proportion of enlightened men, whose advice would be sought in private (unfettered as they were by differences in rank or social position), and whose influence would be felt by the result of the competition. Finally, the Town Council might have alleged, that as the appointments were made in public, every member felt himself to be at the bar of public opinion,—each individually amenable to public criticism. By the present constitution of the Court of Curators, the majority in most cases are prevented by circumstances over which *they* certainly have no control, from seeking in private the advice of their more experienced colleagues, and too often, when called upon to exercise their curatorial rights, they present the melancholy spectacle of victims to party feeling or private friendship. A case in point will illustrate our meaning:—At an election to a vacant chair, three out of the four representatives of the Town Council are understood to have supported one of the unsuccessful candidates on grounds exceedingly creditable to them and to the object of their interest as private gentlemen, but absurdly preposterous as bearing upon the qualification of the candidate for the chair to which he aspired. By these remarks, we mean nothing disrespectful to the Town Council of Edinburgh, who are the accredited guardians of the city; but we maintain, that in proportion as they are rightly qualified to discharge their municipal duties, will be their anxiety to be relieved of a responsibility which they will feel themselves unable conscientiously to discharge.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.

THE winter session of the Royal Colleges of Physicians and Surgeons was opened on the 2nd inst., with an address by Dr. Argyll Robertson. Dr. Moir, President of the Royal College of Physicians, presided; and among others present were—Drs. John Smith, Pattison, Robert Paterson, Cumming, R. Malcolm, Charles Bell, J. D. Gillespie, President of the Royal College of Surgeons; Omond, Inglis, Handyside, Stevenson Macadam, Annandale, Littlejohn, M. Duncan, P. H. Watson, G. W. Balfour, Arthur Gamgee, &c. Dr. Robertson's address embraced the importance of the studies pursued by medical students, the best methods of mastering the subjects required for the qualification to practise, and the subsidiary methods of gaining information. Dr. Robertson, who dwelt upon the education necessary to a higher professional standing, and expressed his views on various points in connection with medical education, thought in these modern days, when the facts of science were so multiplied, and the generalizations so little able to keep pace with their increase, an additional year should be accorded to study, if the student was to excel. That additional year might be best employed by the study of special subjects, either at home or on the Continent. The advantage of study abroad could scarcely be overstated, and he expressed his desire for the formation of some travelling fellowships in connection with the schools. He observed that in Russia and Austria the State was alive to the advantage to be derived from foreign education, and had instituted a system whereby the most deserving students were sent at the expense of Government to other countries.

EDINBURGH ROYAL INFIRMARY.

AT a meeting of the managers, held on Monday, the 1st November, Dr. Claud Muirhead and Dr. Thomas R. Fraser were appointed assistant-physicians to the Royal Infirmary.

THE interim interdict raised by two of the Governors of George Watson's Hospital, against the Company and Governors selling the hospital and grounds to the Royal Infirmary of Edinburgh, has been refused.

THE following mark of respect was paid to Professor Syme, by Sir Alexander Grant in his opening address, and was received by the audience with the most prolonged and enthusiastic applause:—The second of our body, who, owing to impaired health has retired, is the illustrious Professor Syme—whose achievements in the chair of clinical surgery during the last thirty-six years have been among the chief glories of the University, and have carried his name and ours far beyond the limits of this land. The announcement of Professor Syme's resignation has elicited from his numerous and widely-scattered pupils a note of gratitude and admiring respect, which has vibrated into the far East, and now returns swelled by the concurrent voices of the most eminent members of the surgical profession. But though he retires from his active duties as a teacher among us, there seems to be no reason for considering Professor Syme's career to be concluded. Even though he should lay aside his instruments, he may yet continue, by his knowledge, his experience, and his wisdom, to benefit and assist mankind. "Non enim virique, aut velocitatibus, aut celeritate corporum, res magnæ geruntur, sed consilio, auctoritate, sententiâ; quibus non modo non orbari, sed etiam augeri, senectus solent."

THE new Professor of Surgery at Glasgow University (Dr. Macleod) opened class last week.

HEMORRHAGIC MALARIA.

Dr. L. Michel (*N. O. Journal of Medicine*), in an elaborate article, describes a disease peculiar to the Southern States, and which was first described in 1867. It is a disease due to malaria, and is ushered in by a chill of the congestion type followed by high fever, parched mouth, extreme thirst, suffused eyes, restlessness and anxiety, sighing respiration, quick, bounding pulse. During the febrile manifestation nausea and vomiting are extreme. The patient vomits a dark grumous bile. After the nausea has continued five or six or more hours jaundice and bloody urine show themselves. The suffused eyes now become instantaneously yellow, and the red skin changes to a bronzed yellow. With the hæmaturia we have pain in the back, well defined in the region of the kidneys. The tongue varies in appearance from a pale milky colour to a straw colour, and skin dark brown. After a time a remission occurs, in which there is a decided abatement in all the symptoms, except the nausea and vomiting. During the remission, the skin is frequently less yellow, and the urine becomes clear and limpid, only to reassume its bloody colour upon the invasion of the chill. The skin frequently becomes permanently dark bronzed, and the face, chest, and abdomen studded with profuse hæmorrhagica and vibices, and, should a blister be applied, the cuticle will be filled with bloody serum. The bowels are usually constipated, through sometimes there are copious dejections of dark, tarry, feculent matter. The mind is usually clear. It mostly runs its course in from four to twelve days. Autopsies reveal extreme rigor mortis. Muscles very red. A yellow colour pervades the brain, chest, and abdominal organs. Stomach filled with dark grumous bile. The spleen much enlarged, and hard and solid. Kidneys enlarged, and presenting the appearance of passing through severe inflammatory action. Treatment best adapted for this disease is, first of all, to give large doses of mercurials, followed by oil, and after the bowels are moved to give large doses of quinine, with capsicum, until the quinine has produced a decided impression. For the hæmaturia, astringents with opium may be given.

REGISTERED FOR TRANSMISSION ABROAD.

THE MEDICAL PRESS AND CIRCULAR is published simultaneously in London, Edinburgh, and Dublin, every Wednesday morning. Price 5d. Stamped 6d.

By Post to Annual Subscribers, £1 2 6

„ If paid in advance 1 1 8

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, NOVEMBER 10, 1869.

THE CONTEST FOR THE GLASGOW AND ABERDEEN UNIVERSITIES.

OUR medical contemporaries are pursuing a strange course in reference to the coming election for the seat vacated by Mr. Moncrieff. We have already remarked how the *Lancet* has left the party to which for many years it was pledged to support Mr. Gordon. Last week it returns to the subject, and, without assigning a single reason, expresses a “trust that Mr. Gordon will receive the unanimous support of the medical graduates.” Why? It was repeated over and over again that neither candidate possessed any special knowledge of, or interest in, the Medical Profession; and now, after being asked week after week to wait to see if a medical candidate could be found, our elderly contemporary pronounces dogmatically in favour of one lawyer as against another, and chooses the opposite political side to that which it has always professed. Shame of the elder Wakley, whence this betrayal of the principles on which you founded your Journal?

It is commonly said that some people care only to be on the winning side, and that a kind of suspicion that Mr. Gordon will head the poll explains this strange tergiversation. Would it not have been better to make some special utterances on medical reform the test of support in a medical paper?

Another paper goes further in the same direction. The *Medical Times*, strongly Tory as it has of late years become, more naturally gives its feeble aid also to Mr. Gordon. In doing so, however, it is either very ignorant or does not care for truth when it speaks of “Mr. Smith’s studied pro-estations of ignorance of the subjects which are of the greatest interest to the medical graduates.” This statement, be it observed, is circulated four days after Mr. Smith has forwarded to every medical graduate a letter addressed to Dr. Andrew Clark on this very sub-

ject, in which he distinctly pronounces for a representation of the Profession in the Medical Council, and for remuneration to medical men for public services. By all means let Mr. Gordon’s friends push him all they can, but, in the name of common honesty, let not the professional press be the means of suppressing the truth.

The Journal of the Association has at least been guiltless of such unjust conduct, inasmuch as it has printed Mr. Smith’s letter to Dr. Clark, dated November 1, and also a letter from Mr. Gordon to his London agent, dated November 3, and which seems to have been written in consequence of the appearance of Mr. Smith’s manifesto. This is a fair and gentlemanly mode of conducting the contest, and we think those who urged Mr. Smith first of all to adopt this course have benefited their Profession, inasmuch as they have compelled each of the candidates to take some notice of medical questions.

We do not intend here to offer such advice as our contemporaries have indulged in. Our readers are quite able to judge for themselves. Had there been a medical candidate, the question would have been very different. The Profession is not adequately represented in the House of Commons. None but a medical man is likely thoroughly to appreciate, or even understand, many important questions. It would, we think, be a great benefit to the public to have a large number of medical men in the House; and assuredly a constituency so largely made up of graduates in medicine would be a fitting one to be thus represented. We are aware that a number of the electors on this occasion have agreed to sink party and make medical politics the one question to decide their votes. In doing this they are doing good service, by forcing upon the candidates these vital questions. The contest will be a close one, and a few votes will turn the scale, and for this reason they do well to be firm. The statements of both candidates are before the electors, and will be attentively studied. We have carefully perused both, and, though neither perfectly satisfies us, we confess that we are gratified that so much has been extracted from each. It is, perhaps, as much as could have been expected at first from two lawyers. Possibly something still more precise may yet be obtained. Mr. Gordon has great advantage in the contest from his former official experience and his last year’s contest, as well as from his popularity and energy. On the other hand, Mr. Smith’s great distinction as a University man, and his brilliant career in science, unquestionably gives him the prestige in such a constituency which was so well put forth by Sir Wm. Thompson in his favour. Then for us there is this, that he has openly professed that, if successful, he would look upon himself as the counsel of the Profession in the House. We should therefore only have to agree upon a programme and he would undertake it as his brief, and do his best to win our cause. This would assuredly be the best use to which the Profession could put a barrister it had sent to the House.

“SYPHILOGRAPHY FOR LADIES.”

UNDER the above captivating title, we have a leader in one of our contemporaries directed against the views of a writer of an article upon Prostitution in the July number of the *Westminster Review*. The author of the article in the *British Medical Journal* is evidently a man of the most profound knowledge of the subject he speaks upon. His observations upon syphilis and venereal diseases bespeak

the "master," the acute observer of disease, and form a great contrast to the shaky views held as to the gravity of such diseases by some illustrious, though less accurate clinical observers, such as Mr. Simon, and other persons who have recently interested themselves in questions relating to prostitution. We have learnt much from the article; it has deeply interested us; and the more so that, we hasten to add, we entirely disagree with the conclusions of the writer of it.

In fact, the article was written a week too soon. Had the author of the article but waited until the fate of the lady students at Edinburgh was decided, and had had time to read the speeches of Dr. Hughes Bennett, Dr. Alexander Wood, and Professor Masson, he would at least have had some other opponents to attack, in addition to the learned writer in the *Westminster Review*; and we believe his article would have been less open than it is at present to hostile criticism. For what, after all, is the marrow of this article? Is it not that the author of it does not like women to be taught anything about syphilis, because, in some cases, "ignorance is bliss," and that he greatly prefers the ideal of an innocent woman, unsuspecting that there are such horrors as prostitution and syphilis around her to a *femme savante* of the type of one of the heroines of George Sand, or of Balzac? Like Dr. Andrew Wood the other day, at Edinburgh, he does not like the idea of a lady coming out of a dissecting room. Well! but, after all, do not nurses do all sorts of disagreeable things, and are we to despise them because they do so? Is our ideal of a lady to be based on the Chinese one, of a being too sensitive to be annoyed by contact with the real sorrows of human life, and only fit for performing on the piano, looking beautiful, and being always a graceful and an amiable member of a small circle of admiring and loving friends? If this be the ideal of the writer of the article we speak of, will he not kindly allow other men to have a different ideal of woman's character?

For, if he will admit of difference of opinion on this question, we shall at once confess, that our experience of life has been, that the most estimable and agreeable (to us) of the sex have been those who have had a desire to undertake to combat with the difficulties and miseries of human life, and have not been too particular about soiling their hands, or afraid of looking at "unclean things." The word "unclean" used by Dr. Andrew Wood and others, indeed, is one of the most misleading of all expressions. Pork is "unclean" to some Jews. The touch of a pariah is "unclean" to a Brahmin. Sentimentality all of this. Utility is quite left out of sight by us in such cases. In fact, the arguments used by the writer in the article in question are all sentimental, not utilitarian. Does not the writer of the article see at once, and none better than he, that the idea of instructing women in medicine at all is quite incompatible with keeping them in the dark about syphilis? Go to any out-patient department in London, and what do we find? Why, perhaps, that every third or fourth case among the surgical patients, at least, is venereal in its character. Visit the Ophthalmic Hospital at Moorfields, and observe how many of the diseases of the eye are syphilitic. Then occupy yourself with skin diseases or diseases of children. Syphilis again and again meets you at every turn. In fact, scrofula, consumption, syphilis, and cancer, are the leading diseases of our race; and you cannot teach medicine at all without showing your pupils cases of all of these plagues.

But we dare say our author will say, "Ladies should not enter the Medical Profession at all; I don't approve of their doing so." Such was the opinion also of the illustrious Mr. Syme. Well, these gentlemen may be right; but let us hear what is said by some other able medical men on the contrary side. Dr. Hughes Bennett is reported, in the *Scotsman* of October 30, to have recently said that "he used not to be able to understand how *lovely woman* could hang over a putrid corpse and dissect the tissues of that body; but it had recently come under his notice that some ladies in Paris had been complimented by the Professors on the splendour of their dissections. So that,

what was the use after this of talking of the impropriety of women dissecting? The medical faculty of Paris was, he might say, if not the first, unquestionably one of the first faculties of medicine in the world. The study of medicine, like the study of other things, was not a matter of sex: it was a matter of mind and ability." These are the arguments we should like to see attacked by our learned *confrère* of the *British Medical Journal*. Or, will he be kind enough to inform us whether he thinks there is anything degrading in the practice of the medical art which should prevent women from entering the Profession? Surely not! That lady who was Professor of Anatomy in Padua was not degraded thereby; nor were Mesdames Lachapelle or Boivin degraded by their knowledge of the noblest of all the sciences, the one which teaches us to live a long and healthy life.

We are never sure, however, that any person, even those holding identical opinions with ourselves on most other social topics, will agree with us about the question of the "rights of women." Experience has taught us not to rely on any such agreement. But we do know that some of the most practical members of the Profession in London are quite of the opposite opinion to that of the author of the article in question, as to the point whether women should learn anything about medicine, or, consequently, about one of its component parts, syphilis. It is a hopeful sign of the times, however, when such stirring questions are brought before the notice of the learned Profession of Medicine. We seem to have got into the age of revolutions. Every ancient custom is being questioned, and, if found to be absurd, is in danger of perishing; all new doctrines are likely to have a fair hearing and a chance of being practically followed out if found to be true. The admission of women behind the scenes in medicine and in other professions is loudly demanded by some, on the grounds of justice and of the highest utilitarianism. It is deemed by not a few that Nature should be known as widely as possible to as many citizens of both sexes, in order that, conjointly, they may endeavour to shield our race from as many calamities as they can. And were we to point to one calamity greater than another, and one wherein the assistance of educated women could be more useful than in another, we should surely name those mortal contagions which assail the very fountain-head of human happiness, the health of the infant, and which poison the domestic peace of so many a couple. If we are to have medical women, then, let us not hide any part of human suffering from them, and thus we may, perhaps, find that the *Westminster Review's* article was not so far wrong after all.

THE Council of the Royal College of Surgeons of Ireland met, we understand, last week to take into consideration the resolutions adopted at the last General Meeting of the College:—

"Proposed by Dr. Darby, seconded by Dr. Martin, and resolved—That the Council be requested to consider the question of the propriety of seeking for a new Charter, and also the subject of remunerating Members of Council for attendance upon the several examinations, and to report at an early date to a meeting of the Fellows specially summoned for the purpose."

The subjects referred to in this resolution had been under discussion in the Council last year, and it had been then decided that it was not expedient that a new Charter should be sought for. The matter was anxiously discussed for the second time last week, and a Committee was appointed to draw up a Report for presentation to the College. The feeling of the Council was all but unanimous against the proposition. It was felt that, although there were points in respect of which the existing Charter required emendation, they were not of such vital interest as

to justify the College in abrogating its prerogative. To obtain a new Charter it would be necessary, as the first step, to surrender that which it now possesses, and to take chance for the provisions which might be fixed by the Government for its future incorporation. Bearing in mind the disturbed state of the public mind on questions of education and the administration of Colleges, it was considered, even by those who would otherwise have most ardently supported the movement, that there could be no less appropriate time than the present for plunging the College into voluntary disestablishment. There is a power given in the Charter for its amendment on the approval of the Secretary of State; but the exercise of this privilege has been found to be practically prohibited by the expense which it entails.

In respect of the payment of Councillors for attendance at the examinations, it was decided also that the payment should continue.

We understand that a notice of motion has been submitted for future discussion, to the effect that the Fellowship Examination shall be so far modified as to admit Licentiates of long standing, whose professional character may be approved on the writing of a thesis.

Notes on Current Topics.

General Medical Council.

DR. HUMPHRY, of Downing College, has been elected representative of the University of Cambridge in the General Medical Council, vice Dr. Paget, of Caius, elected president thereof. Mr. C. Lestourgeon, of Trinity, was also nominated. Dr. Humphry polled 68 votes; Mr. Lestourgeon, 15.

The Success of the Compulsory Vaccination Act.

DR. ROSS, the Medical Officer of Health for St. Giles's, has recently inquired into the operation of the Compulsory Vaccination Act in that populous district; and in a report to the Board of Works, he states that "during the year 1867, the year preceding the operation of the new Act, the mortality from small-pox was 31. On the first of January, 1868, the Act came into force, and during that year the mortality sank to 6; whilst during the past nine months of the year 1869, there has not been registered a single death from this disease. "Stronger proof," Dr. Ross adds, "could scarcely be afforded of the beneficial operation of any legislative measure for the arrest of a frightful disease."

British Corn Flour.

MESSRS. COLMAN, of Norwich, have recently introduced to the public a new farinaceous food, prepared from rice, and termed "British Corn Flour."

We have procured specimens of the article in question, and submitted them to a careful chemical and microscopical examination. We find that it consists solely of the farina of rice, from which every particle of cellulose or woody fibre has been removed. This article has evidently been prepared from an exceedingly fine variety of rice, from which a farina has been produced, free from the slightest trace of irritant husk, that is at once nutritive and agreeable

in the extreme; hence the farina is relatively, as compared with the whole grain, richer in the carbohydrates and poorer in albuminoid substances. The amylaceous granules of rice are naturally very small, and they probably yield more readily to the action of the digestive fluids than do any of the starches derived from other plants. Beaumont found that boiled rice was digested in an hour, while arrowroot—a food remarkable for its easy digestibility—required one hour and a half to effect its digestion. We find that in gelatinizing power $7\frac{1}{2}$ parts of British Corn Flour is equal to 9 parts of arrowroot and 14 parts of wheaten starch. The opinion has long been current among physiologists that isinglass and other forms of gelatine are wholly unnutritious. If such be the case the sooner that article is replaced the better.

The British Corn Flour appears to us to be an exceedingly bland, easily digestible, and nutritious food, specially adapted for children and invalids. We understand that it has been used with good results in most of the Dublin hospitals, and is now being tried at some of the principal London hospitals. When it was the fashion to estimate the value of a food by the amount of nitrogen which it contained, rice was regarded as the least nutritious of the cereal grains. Recent investigations show, however, that the energy of the body is chiefly maintained by the carbohydrates, of which rice contains a larger proportion than is found in any other grain. Dr. Chambers recommends such a diet as that furnished by British Corn Flour as the most suitable during "acute catarrhal bilious attacks, at the commencement of treatment, or even chronic gastric cases, and whenever a dusky complexion, hypochondriasis, &c., show that arrested moulting has caused a collection in the body of effete tissues."

In conclusion, we may state of British Corn Flour that in every case where an amylaceous diet is indicated this farina is, in every respect, superior to arrowroot, tapioca, and the other food starches. It is better flavoured, more digestible, blander, and more nutritious. As a food for children, the British Corn Flour has many and obvious properties to recommend it.

Never say Die!

Nihil sub sole novi is a fallacious proverb! Yet we wonder how the editors of the *Annale de la Médecine et de la Chirurgie Etrangère*, the Florence paper, *L'Italie*, and our own *Pall Mall Gazette* and *Public Opinion* can reconcile their consciences to the publication of the following:—

EXTRAORDINARY FEAT IN SURGERY.—A Florence newspaper, *L'Italie*, extracts from the *Annale de la Médecine et de la Chirurgie Etrangère* the following extraordinary history: On the 18th April, 1868, in the prison of Villarica, province of Minas Geracs, in Brazil, two men, named Aveiro and Carines, were executed at the same time. Dr. Lorenzo Y Carmo, of Rio Janeiro, obtained permission to profit by this event, in order to experiment on the power of electricity. Dr. Carmo's design was, if possible, to unite the head to the neck after decapitation. The heads of the two criminals fell within a few minutes of each other into the same basket, first that of Carines, then that of Aveiro. Immediately after the second execution, a compression was effected on the carotid arteries of one of the heads, so as to stop the hemorrhage. The body was then placed on a bed, and the head was stuck as exactly as possible on the section, and kept in that position. The cells of a powerful electric pile were applied to the base of the neck and on the breast. Under this influence the respiratory movements were at once perceptible, and the head was fastened to the body by stitches and by a special apparatus. The physio-

logist wished to ascertain for how long a time this appearance of life could be artificially maintained. His astonishment was great when he saw, at the end of two hours, not only did respiration still continue under the influence of the electric current, but that circulation had even resumed a certain regularity. The pulse beat feebly but sensibly. The experiment was continued without intermission for sixty-two hours. A little later, signs of life manifested themselves spontaneously in the head and limbs, till then deprived of motion. At this moment the director of the prison, arriving for the first time in the experiment-room, observed that by a singular mistake the head of Carines had been applied to the body of Aveiro. The experiment was continued notwithstanding. Three days later the respiratory movements produced themselves, and electricity was suppressed. Dr. Carmo continued to assist the process of cicatrization, which progressed under the most favourable conditions. By means of an œsophagean probe, liquid nourishment was introduced into the stomach. At the end of about three months the cicatrization was complete, and motion, though still difficult, became more and more extended. At length, at the end of seven months and a half, Aveiro-Carines was able to rise and walk, *feeling only* a slight stiffness in the neck and a feebleness in the limbs.—*Pall Mall Gazette*.

The story flavours of Yankeeism; but it is incompletely narrated. We should have had a glowing description of the plan of union of spinal cord, and artificial pneumogastric nerves, to assist the "œsophagean probe." The *Pall Mall*, after the sensational, scientific way of saying things peculiar to it and its foster-brother, the *Lancet*, which have become so intimately associated in ideas of late, should have added a little of its own by way of variety, descriptive of the individual's feelings on awaking and discovering his head on another man's shoulders; all this would have gone further to support Cicero's logic, "that nothing is so unaccountable or improbable, so revolting or devoid of ornament, as not to appear bright and truthful by a gorgeousness in description." The story is extensively copied into the provincial Press, so that the name earned by our cotemporary in Ireland, of the *Pall Mall Bully*, is certain, if things continue in the same strain, of being converted in England into the *Pall Mall Gull*. The great Dr. Lorenzo Carmo, we must not forget, whose imaginative powers are a Godsend for the sensational papers of England, and we hope, for his and their sake, he may go on *ad infinitum* "cicatrizing" decapitated criminals. There are many broad shoulders we know, which would be nothing the worse if they possessed their neighbour's head; and as money can purchase anything, we cannot predict what, in this sensational age, may next transpire.

International Standard Measures.

THE metrical system and the standard measures of France have occupied the attention of the Academy of Sciences of Paris more than once of late. M. Chevreul, the eminent chemist, took an opportunity to protest scientifically against the adoption, for the purposes of a standard measure of length, of a measurement of a portion of a meridian of the earth, which had not at the time, and has not yet, been positively determined, but for practical reasons arrived, at the conclusion that the standard *mètre* of the year VIII preserved in the archives of France, should be maintained, and proposed that an international commission should undertake the task of multiplying copies of such *mètre* and other standard measures, calling to its aid for such purpose all the scientific means in existence. A note was read before the Academy, showing that the Academy of St. Petersburg, adopting the same ideas as M. Chevreul,

had expressed the desire that its members should, in future, use none other than the French metrical system in their publications; that it had constantly recommended its adoption by the various branches of the Russian administration, the universities, and scientific corporations; and stating that next year the meteorological observations in Russia will be published in the metrical system. At a subsequent meeting of the Academy, it was announced that the Berlin Academy of Sciences had adopted the decision of the St. Petersburg Academy respecting the metrical system and excepted the existing *mètre* and kilogramme as absolute standards of measure, and joined in the recommendation of an international commission for the production of prototypes. The assent of the Royal Society of Great Britain to these propositions is hoped for as all that is needed for the adoption of a general international metrical system.

Health of Dublin.

IN the Dublin Registration District the births registered during the week ending October 23rd, amounted to 159. The average number in the corresponding week of the years 1864 to '68 inclusive, was 149. The deaths registered during the week were 126. The average number in the corresponding week of the previous five years was 154. Fourteen deaths from scarlatina were registered during the week, being 1 in excess of the number registered in the previous week; and being 8 more than the average number for the corresponding week of the previous five years. Measles proved fatal in 10 instances. Fever was the cause of 7 deaths, viz.:—1 from typhus: 5 from enteric or typhoid; and 1 from simple continued fever. The deaths of 5 children were ascribed to diarrhœa. Bronchitis proved fatal in 6 instances, and pneumonia or inflammation of the lungs in 4. Twelve children died from convulsions. Phthisis or pulmonary consumption caused 13 deaths. One death resulted from nephria or Bright's disease, and 3 from heart disease. The deaths of 3 persons who were drowned were registered. One of these deaths occurred at the Custom-house quay, Dublin; and the other two at Kingstown. The death of a watchmaker was registered whose age is stated to have been 101 years.

The Digestive Powers of Pancreatine.

IN the Academy of Sciences of Paris M. Chauvin and M. Morat have recently read a paper "On the Pancreatic Juice," and the conclusions at which they have arrived are—first, that the general results of their experiments on artificial digestion with this fluid agree with those made by older experimenters, from Eberle to Claude Bernard. Secondly, that in such experiments with artificial digestion, the action of the pancreatic juice is not checked by the presence of gastric juice, nor by hydrochloric acid considerably diluted with water. Thirdly, that at ordinary temperatures, and in inert vessels, the juice does not act so energetically as when maintained at the temperature of the body, and under the influence of the movements of the digestive fluid. Fourthly, in the digestion that ordinarily takes place in the stomach—and this is a capital point—the pancreatic juice preserves its energies intact, notwithstanding the presence of the gastric juice, and may initiate in the interior of the stomach a complete digestion of the three species of alimentary substances. And, lastly, they

state that in a clinical point of view they have obtained remarkable results with the aid of pancreatic juice and extract.

The Profession as a Trade.

At a recent meeting of the Mansfield Board of Guardians, Dr. J. Senior Turner, of Alfreton, the medical officer of the fifth district of the Mansfield Union, a most respectable and successful practitioner, was given two months' notice by the Board before his district was taken from him and conveyed over to a Mr. Diver, from whom the Clerk read a letter wherein this Mr. Diver, asked for the appointment "because he had taken a house at South Normanton with the intention of residing there."

Dr. Turner informed the Board, as we gather from the report of the meeting in the *Midland Gazette*, that although non-resident in the district, he believed the poor could not be better attended than they were by him; but the Chairman replied that they were obliged to appoint a medical practitioner, if duly qualified, who resided in the district; *that the law left them no alternative*. It comes to this, that Mr. Diver, who had just arrived from Scotland armed with a Scotch diploma, would successfully supplant the present medical officer in two months. We question that the Chairman was correct in his observation that the "law left them no alternative," other than to displace an old, well-tryed, and faithful officer, and appoint a young newly qualified man in his place. The most important feature in the case is this: Mr. Diver tells the Board he has taken a house at Normanton, and asks for the appointment because Dr. Turner does not reside in the district, and this week this Mr. Diver, with the alphabet after his name, writes to the editor of the *Midland Gazette* the following spicy production, which reflects little credit on his schoolmaster and the profession to which he takes care to inform the public he belongs, *sic* :—

To the Editor of the Midland Gazette.

SIR,—In your impression of the 9th inst., you state that I have taken a house at South Normanton, which has led many of my friends to believe that I am giving up my present practice, and is likely to do me a serious injury; therefore you will oblige me to state that I have not taken a house at South Normanton, nor anywhere else, except in this town, where my practice will be carried on as usual.

Should I be elected to the No. 5 District, I have promised the Guardians to have a surgery in the district, and visit it daily.

Trusting that you will give this a conspicuous place in your valuable paper, I am, sir,

Yours obediently,

W. H. DIVER, L.R.C.P., M.R.C.S.E., L.M.
Sutton-in-Ashfield, Oct. 21, 1869.

This Mr. Diver is very kind offering to release Dr. Senior Turner of his appointment, but we hope the Mansfield Board of Guardians will not only reinstate Dr. Turner to his legitimate right at the end of two months, but that they will require of this Mr. Diver an explanation of his letter, and, if he be unable to give one, to pass upon him a vote of censure that other Boards may be prepared to deal with him. Our language cannot be too strong in our condemnation of this professional trading, and it will be our duty time after time to expose these occurrences, which we hope, for the sake of the character of the profession and all parties concerned, will be few and far between. With regard to the serious injury this Mr. Diver fears his practice will sustain, we learn from a competent local authority

that it means "the puff direct," and that there are few medical gentlemen in the locality in which he resides likely to trouble themselves about him or his affairs, one way or the other. But when we find men deviating from the path of rectitude, it is a duty we owe the Profession to keep them right in principle and in practice, whilst we feel called upon to support, at such a time, gentlemen in Dr. Turner's position, however unenviable it may be to him to class both together.

Dr. Richardson's Lectures.

On Tuesday, Nov. 2nd, Dr. Richardson delivered the second of his present course of lectures. The lecturer showed a rabbit in a state of profound sleep from 15 grains of chloral injected into the rectum; the sleep would probably last about 14 hours.

Passing to the special subject of the discourse—artificial respiration—a very interesting experiment was shown of a rabbit, narcotized almost to death by methylic ether, in a glass jar, and laid apparently lifeless on the table. To restore animation, Dr. Richardson inflated the lungs with a small india-rubber bellows, suspending the process the instant he saw the first sign of returning motion, and thus the animal was brought back again to life. In another experiment of the same nature the narcotizing process had gone too far, all action of the heart had entirely ceased, and consequently the inflation of the lungs with air proved abortive. A case was related of a child on the verge of suffocation from croup, and where tracheotomy seemed decidedly indicated, being happily restored to life and health by the careful inflation of the lungs by Dr. Richardson, with the india-rubber bellows.

It was gratifying to observe that the audience at this lecture was so large as completely to fill the room, showing that the very moderate fee which, at the suggestion of his friends, Dr. Richardson has fixed for the course has rather had the effect of increasing the already numerous attendance at these popular lectures.

Natural History Society of Ireland.

WE learn with much regret that a schism, which threatens the Society almost with extinction, has arisen in the Natural History Society of Ireland. At a recent meeting of the Society, a motion was made and supported by a certain party, which was felt to amount to a charge of neglect of duty on the part of the honorary secretaries. Both of these gentlemen thereupon resigned their offices, and they were followed in their withdrawal by several of the most valuable members of the Council and of the Society. At the last general meeting the letters of resignation were read, and after a marked expression of regret on the part of the Society, that the adoption of such a course by the secretaries had seemed to be called for, a motion was unanimously adopted that their resignations be not accepted, and they were, on a ballot, re-elected.

The Society has been for many years almost the only scientific body which has been in a prosperous condition in Ireland. It is still financially good, and it will be a subject of much regret if an ill-advised and undeserved attack on its officers shall prove to be seriously injurious to its efficiency.

Dr. Rattray on the Diet of Seamen.

ALTHOUGH we are past the days when scurvy was so common that a large portion of the crews of both our Royal Navy and of the Mercantile Marine were disabled from service by its ravages, there is much yet to be accomplished for our sailor population before we can hope that they will be in a condition which the sanitary observer can look upon with anything like satisfaction. Worst of all, amid instances of overcrowding and bad ventilation, are the examples related to us of the overcrowding on board many of our most splendid looking vessels. Oh! for a Miss Nightingale who shall embark on board some of those ships, and write us a volume such as that she has gifted the nation with upon hospitals!

The diet of seafaring people is much better than it used to be, of course; but, even in diet, much improvement might be made. In the first place, it seems that too much use is made of salt provisions, and there is far too little variety in the diet list. It is doubtful whether the best of all anti-scorbutics can completely counterbalance the continued use of salted pork or beef. Dr. Rattray would omit almost entirely the use of salt meat from the diet list of the Navy. The pound of salt meat he proposes to replace by three-quarters of a pound of preserved meat, or half a pound in the tropics, and he proposes to replace the daily ration of rum in temperate climates by coffee; and we congratulate Dr. Rattray on this admirable change. He next proposes to alternate the pea soup and flour pudding of every day with barley broth and rice, sweetened by treacle. The frequent issue of soft bread, at least in harbour, is recommended, and a better kind of cook is suggested. Why can't they have women cooks in some of our sea-going vessels? An English man cook is usually such a poor fellow compared with a woman. Dr. Rattray suggests that at sea a half ration of chocolate issued to each man at their morning and night watches would be useful. All these changes in diet, he urges, could be carried out easily enough. Perhaps it would not be a good thing always to feed the crew on preserved meat, since it appears that this food is rather insipid. A little salt meat might occasionally be used for a change. The preserved meat, however, is greatly relished by the sailors. We thoroughly agree with the views of Dr. Rattray; and believe that if his suggestions were carried out, the life of a sailor would be a far more healthy one than it has hitherto been,—so far, at least, as diet goes, which is not so important, however, as ventilation.

Extension of the Contagious Diseases Act.

WE have before us—1. "Bishop Alford's protest against the Act for Licensing Prostitution, called the Contagious Diseases Act:"

2. "Observations on the Attempt which has recently been made to introduce into Great Britain the iniquitous Continental System of Licensed Prostitution. Journal Office, Northampton:"

3. "Report on the Contagious Diseases Act, by John Simon, Medical Officer of the Privy Council," &c.:

4. "Contagious Diseases Act Meeting, at the Royal Hotel, Bristol." Newspaper Report.

Nottingham seems to be taking a foremost part in its opposition to the Contagious Diseases Act extension. Dr. C. B. Taylor, F.R.C.S., expressed his conviction in the

meeting at Bristol, that the Bill would fail in accomplishing its purpose, and, besides, that it was fraught with much danger to the interests of society. The fact that the weaker sex alone is subjected to a brutalizing examination must of itself render the Act futile in good results, as far as the public health is concerned. Dr. Taylor adds that true primary syphilis, the only disease which affects the constitution, cannot be detected in the female, and thus cannot be checked by legislation. He pointed to one fact, which is certainly a great blot in the system, viz., that there was actually no definition of prostitution, so that positively the whole of the women in the country were placed by the Act at the mercy of a policeman's suspicions. Under the 17th Section, practised police spies could bully, cajole, and terrify comparatively innocent, aye! entirely innocent, girls into enrolling themselves in the ranks of registered prostitutes. It was in evidence that already in England, respectable married women, and at least one virgin of the tender age of 14 years, had been grossly violated. He pointed out the power of denunciation which by the Act was placed in the hands of brothel-keepers, procuresses, and others; and said that in none of the places had denunciation of disease been what fairly could have been expected.

The only point in Dr. Taylor's arguments with which we are slightly at variance with him is with regard to the question of the gravity of the diseases gonorrhœa and syphilis, and the power of checking contagion by sequestering the sufferers from these complaints. Gonorrhœa in the male is a very dangerous complaint; and if women had hospitals where they could enter when suffering from acute vaginitis or uterine catarrh caused by gonorrhœa, doubtless fewer men would suffer from stricture of the urethra and all its horrors. Then, too, if women with indurated sores or mucous tubercles on the vulva, could remain in hospital until well, which they would, we believe, be only too glad to do in most cases, there would not be so much of the fearful malady syphilis about. Dr. Taylor, however, we are sure, would have no objection to the extension of hospital accommodation for women suffering from such diseases, so that we only differ very slightly from his views.

The views of our theological brethren are usually scarcely scientific enough for us medical men. They declaim too much about sin, and speak too little about human suffering and disease. In fact, we would usually care but little to have the clergy of to-day on our side in any public question, except in so far as their influence might be useful to assist in carrying the point. It was an evil day for theologians when they gave up studying medicine. The monks of the middle ages studied both the cure of souls and bodies, and hence could talk rationally on social questions. Hence, although we may welcome the assistance of the clergy in warring against the provisions of the Contagious Diseases Act, we cannot stomach the reasons they assign for their objections to it. Most of them seem to think that the Deity sends gonorrhœa and syphilis to keep men and women in the path of duty and marriage—an argument which we can only class as inept and silly, and only fit to be treated with contempt.

THE Medical Club has elected Dr. Livingstone an honorary member, and sent out an invitation to him to occupy the Club house, on his return to this country.

St. Bartholomew's.

In the place usually allotted to announcements of Cabinet Council and other official kind of notices, last Friday's *Times* contained the following announcement:—

"The Treasurer of St. Bartholomew's Hospital requests that the public and the Governors will suspend their judgment upon the recent charges made against the management of the hospital. He proposes to call a general meeting of the Governors, at which he will enter fully into the nature of these charges, to which he is convinced he can give a completely satisfactory reply."

We hardly think it worth while to inquire why the leading journal has assigned such importance to an individual's advertisement. Still, if the Treasurer of the Royal Hospital has anything to say we shall be glad to hear it. All we say is, whatever defence is put forward should not be delayed.

The *Times* last week gave a comparison between the London Hospital and St. Bartholomew's, showing the superiority of the London. The *Pall Mall Gazette* thereupon stated that the statistics were still more to the disadvantage of St. Bartholomew's. The *City Press*, on the contrary, disputed the accuracy of the deductions drawn by the *Times*. We have not space to enter fully on the matter now, but shall return to it.

New Chemical Nomenclature.

At a congress of Italian naturalists, which has recently taken place in Catania, Professor Zurno, of Naples, proposed a reform in the chemical nomenclature of organic bodies, and a committee of Italian chemists has been appointed to draw up a new system of nomenclature for presentation at the next Congress, in 1870.

The Inauguration of Dupuytren's Statue.

It was hardly to be expected that after the lapse of thirty-five years from his death, and at a distance of one hundred and five leagues from Paris, the assembly for the inauguration of Dupuytren's statue would be sparsely attended. The number of those who were present was small, but the character of those who represented the Institute and the Academy was such as to cause us to forget that no delegate was present from the Faculty of Medicine, on which Dupuytren shed so brilliant a lustre. The number of professors from the Medical School, at Limoges, however, amply compensated for the loss.

The ceremony commenced on the 17th of October; it was presided over by Professor Conveillhier, and was held on a great platform erected in front of the statue.

The statue represents Dupuytren as clothed in his professional robes, and has all the character of a man of genius; but the narrowness and irregularity of the site where it is placed spoils the perspective, and robs the work of its proportions.

Six eulogia were pronounced, the first by M. Bardinet, director of the School of Limoges, and the second by Larrey, on the part of the Institute.

At the conclusion of the ceremony the persons present visited the house and chamber where Dupuytren was born, and the day was closed by a banquet.

On Hospital Sunday, at Birmingham, the amount collected was £3,700. This at the Queen's Hospital has it.

SCARLET fever has not decreased in London. Last week's return gives 229 more deaths.

A TRIPLE birth, in Cornwall, was recorded by the newspapers last week.

THE Parisian *Petit Journal* records an act of signal devotion on the part of a medical man. At the Cochin hospital lately, a workman was seized with diphtheria, and asphyxia was impending. Laryngotomy was performed, but the sound could not remove the membranes, which obstructed respiration, and the patient was at the last extremity. The resident surgeon, M. Bully, without hesitation, drew out the sound, applied his lips to the wound, sucked vigorously, and then expelled a mouthful of sanguinolent matter which had obstructed respiration. The patient recovered.

THE surgeoncy of Sir Patrick Dun's Hospital, Dublin, vacant by the resignation of Dr. McDowel, Professor of Anatomy and Chirurgery in the University of Dublin, has been conferred on Dr. Little, son of Dr. Little, of Sligo, and a demonstrator in the School of Physic. We are informed that the term of office is limited for the present to two years and a half, and that permanent arrangements will then be made.

THE nomination of candidates for the representation of Glasgow and Aberdeen took place on Tuesday, 2nd November. The candidates proposed were Mr. Smith, of Jordanhill, and Mr. Gordon, Q.C. The show of hands was in favour of Mr. Gordon. A poll was demanded by Mr. Smith's proposer, which will commence on Monday, the 15th, and will continue for five days. It was objected that a show of hands was illegal, but the objection was overruled.

The new illustrated journal of science—*Nature*—has appeared, and promises to be most successful. It opens with Goethe's rhapsody on nature, translated, with remarks, by Professor Huxley. Other articles are by Sir John Lubbock, Mr. Norman Lockyer, Professor Williamson, and other well-known names. The notice of the late Professor Graham, by Williamson, will be read everywhere with interest. Altogether, *Nature* seems quite "a hit."

THE Session of the Society of Arts will commence on Wednesday, the 17th November, when the opening address will be delivered by Lord Henry G. Lennox, and the Prince Consort's Prize will be presented.

The first course of Cantor lectures will be "On the Spectroscope and its Applications," by John Norman Lockyer, Esq., F.R.S., and will consist of three lectures, to be delivered on Monday evenings, the 6th, 13th, and 20th December. Other courses will also be given during the Session, one, by A. W. Williamson, Esq., F.R.S., Professor of Chemistry in University College, "On Fermentation, especially in connection with M. Pasteur's Researches," having been already arranged. These lectures are open to members, each of whom has the privilege of introducing two friends to each lecture.

Correspondence.

LARGE FAMILIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I think a few words from me at this stage of the discussion may not be amiss. When I introduced the subject in your columns—on the 6th October—and indicated the direction which I thought the discussion might usefully take, it was my intention to retire from the controversy, and watch the result, believing that ample matter for a very interesting and useful correspondence had been furnished under the four heads which I suggested.

The subject was taken up by "J. D. M.," who dismissed my propositions with the remark that "the mere question involved" (in such a comprehensive programme!) "is not one that can occasion much discussion," meaning, I presume, that the questions raised—for there were several, not one only—were settled, and required no argument to prove them correct; but are they settled, and if so, how, and by whom? I must confess that if I had thought them settled, in the sense of being generally accepted, I should not have troubled you with any remarks upon the subject. If "J. D. M." means, as I suppose he does, that few persons would be found to dispute the soundness of my views in theory, how is it that the practice of the community at large is so opposed to their ideas of right? But I differ from your correspondent on that point; I do not think that the public at all recognise the connection between "large families" and the prevalence of vice, pauperism, disease, and premature death, which affect in some way or other, every class, from high to low. Let this question be fairly discussed first, and it will then be time enough to consider the means of controlling the number of births. "J. D. M." has taken upon himself to decide that there are only two plans available, in order to accomplish this end, and "A. G. L.," in your Journal of the 3rd inst., endorses that view,—viz., 1. The seclusion of the wife from the husband. 2. The adoption of artificial means of preventing pregnancy.

"J. D. M." asks whether *this* is the subject intended to be put forward for debate? As far as I am concerned, I answer emphatically IT IS NOT.

I do not think the time has arrived for me to explain my views further than to say that they are based on natural—that is, on physiological laws, and can be carried out without doing violence to morality, sentiment, good taste, or right feeling, and with a decided gain in all directions, especially as regards health, which is an important consideration. I say this much just now, because I think the turn given to the discussion by the two last correspondents is calculated to bring the subject into disfavour with the public and the press; already, very naturally, prejudiced against the idea included in one of the suggestions, and not likely to take very kindly to the other.

I am, Sir, yours faithfully,

November 4th.

PRUDENTIA.

NAVAL ASSISTANT SURGEONS AND THEIR PRIVILEGES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you kindly give space in your valuable journal to a few remarks showing the prospects of naval assistant surgeons? By the Navy List, June 30th, 1869, I see that four assistant surgeons have been promoted during the six months, and only seven during 1868. Now, there are 236 on the list, so that, giving an average of eight promotions, six deaths, and resignations yearly, the men now entering will have at least to wait sixteen years for a rise.

We who joined in 1859 and 1860, and who hope to be at the top of the list in about 1873, will have two men who joined in 1867, or seven years after we did, placed over us as surgeons, according to Circular, May 7th, 1867 (page 324, Navy List), which states that the candidate who passes the best examination of his year will be promoted in five years, the second best after six years, and so on.

So that the assistant surgeons who entered the service in 1866 (the order is not retrospective) will have twenty-four men promoted before them in this manner, of which twenty-four one will have entered ten years after them, two nine years, three eight years, &c.,—not a pleasant thing to look forward to.

Then the great boon lately granted of choice of cabins is nullified by the Dockyard authorities fitting and allotting the cabins for the officers. For instance, I joined a ship, and found she carried a Lieutenant, a navigating sub-Lieutenant, an Assistant Paymaster Engineer, and myself. I came after the Lieutenant in rank, but had the worst cabin. On applying to the Captain, I was told that the cabins were told off in the Dockyard, and fitted so for the officers named, and that he could make no change.

I think it but right that our young surgeons should know what they have to expect in the service.

On entry now, the newly caught assistants are sent to one of the homeships for a few months, to give them time to write to their late fellow-students, and to tell them how jolly the Navy is! how they go on shore without danger or difficulty, and that they have not been the least seasick, particularly if their ship is the old Asia lying at the top of Portsmouth Harbour. But soon a change comes over the spirit of the dream. A big letter on H.M.S. service arrives, and they find they are appointed to H.M.S. Growler or Boxer, going to the Coast of China. To prove this, see Navy List, where out of the fellows who joined in 1867, nine are on the coast of Africa, eight in China, and two in the West Indies.

Then all good appointments are filled by surgeons borne in lieu of assistant surgeons,—an injustice, I think, to men who have been four or five years abroad in the worst climates in the world.

Take Punch's advice to people about to marry, all ye surgeons who think of joining the Navy,—and don't.

I am, &c.,

A. B.

PROPHYLAXIS OF ASIATIC CHOLERA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The accounts which daily come to hand touching the ravages of Asiatic cholera are simply heartrending. I counted upwards of twenty distinct localities in India where this fell disease was reaping an ample crop of victims. If I be satisfied of anything, it is that we have ample means of everywhere checking this hitherto relentless scourge. First, we have at our disposal the ordinary sanitary precautions and appliances as to meat drink clothing exercise and absolute cleanliness on which I need not here further enlarge, next we have it equally within our power to bury every species of animal excretion, feculent and urinous, at once deep or deeply enough in the soil, thirdly and lastly we are to have recourse to dilute sulphuric acid as a prophylactic of the highest possible value. Administer daily to every one, in case of the imminence or actuality of cholera, and without waiting for the disease to break out, half a drachm of the dilute acid, night and morning or morning only, in a little plain or aromatic water. This alone, in the great majority of instances, will I believe keep the disease at bay but, if coupled with sanitary precautions, generally, and the immediate burial of excretions, will, further, I believe render us its complete masters. Keeping off the first causes of Asiatic cholera, whatever they may be, I am of opinion that it is exclusively propagated by infection at first hand or, at second hand, through the medium of the excretions. If I be right in these views, surely to God, the precautions here insisted upon, are worthy of the best attention of practitioners at home and abroad, but especially so in the localities where cholera is at home and which it seems never entirely to abandon.

I am, Sir,

Belfast, Oct. 29, 1869.

HENRY MACCORMAC, M.D.

SCIATICA TREATED BY ACUPUNCTURE.

A gentleman had long suffered from unilateral sciatica, which had proved rebellious to ordinary remedies. Having determined on employing acupuncture, twelve fine needles were selected, which were inserted in the direction of the nerve along the ischio-trochanteric fossa. After stretching the skin tense with the left hand, the needle was seized by the head, and, holding it at an angle of 45°, was passed through the skin in a boring manner about half an inch. All the needles were successively passed and left in place about half an hour, when they were extracted. The patient then rose, and walked with ease and without pain. The cure was radical.—Dr. T. J. Stevens in the *Boston Med. and Surg. Journal*.

MURIATE OF AMMONIA AS AN EMMENAGOGUE.

Dr. Cholmeley (*Practitioner*) is fully satisfied that muriate of ammonia, in a very large number of cases of absent or suppressed menstruation, acts in a very direct and powerful manner in establishing or retaining the flux. He gives the remedy in doses of 10 to 20 grains.

ERGOTINE IN DIARRHŒA AND DYSENTERY.

Dr. Gros, of Germany (*Half Yearly Comp. Med. Science*), recommends *ergotine* in diarrhœa and dysentery. He treated 14 cases of dysentery with it, and had but one death, this being caused by dietetic irregularity on the part of the patient; 25 of the cases were of a mild type. He gives 6 grains in mucilaginous emulsion; and frequently also gives clysters of 12 grains in starch.

In acute diarrhœa the enemata alone are used where it is not desirable to check the discharges too suddenly. Its effect in the chronic-diarrhœa of adults and children is favourable; children take the remedy best in the form of dragées.

The clysters are particularly useful as hæmastatics in the bloody dejections of dysentery.

In one case two doses and two clysters were administered—the latter two days subsequent to the former; cure followed within six days; but there was a slow convalescence, owing to unpropitious circumstances.

FUNCTIONAL VALVULAR DISORDERS OF HEART.

J. M. Da Costa, M.D., Phys. to Penn. Hospital (*Am. Jour. Med. Sciences*), in an interesting paper, styled "Functional Valvular Disorders of Heart," asks if cases of functional valvular disorder ever pass into organic valvular disease? He states that this is a very difficult matter to settle, but believes that it is so. Cases have been seen, few it is true, that had the inconstant murmurs, the examination of which has occupied so large a share of this inquiry, and in which, when encountered after the lapse of time, obvious valvular disease existed. But in every one the enlargement of the heart, which at first was slight, had become a marked feature. Hence, a case might begin with functional valvular disorder attending functional affection of the organ; hypertrophy may follow the functional affection, and, if this becomes marked, valvular diseases may ensue. Such cases have happened, which came under his own observation. Such he believes to be a possible result, and while it is not susceptible of proof—for it may be suggested that the signs of valvular affection were, from the outset, due to a slight but increasing organic lesion—repeated examination of the question, and a careful weighing of the facts, have caused his belief to become a firm conviction. In conclusion, he states, if this sequence be true, how important a lesson it inculcates as to the importance of not neglecting functional affections of the heart; how it teaches us to treat that which if we make light of may pass from a curable into an incurable malady; how markedly it points to the means which will give the agitated organ rest, as alike of value in the present, and as preventive of mischief in the future.

BROMIDE OF POTASSIUM IN TYPHUS FEVER.

Isaac G. Porter, M.D., of New London, Conn. (*Am. Jour. Med. Science*), advocates bromide of potassium in combination with sulphate of morphia in solution in the perilous stage of typhus or typhoid fever. That stage so well described by Graves, when in the latter part of the disease, "subsultus, long-wakefulness, muttering, raving, delirium, cold perspiration, and involuntary discharges," show exhaustion of the powers of life and approaching dissolution. The condition is atonic, and forbids everything which is in its nature depressant or destructive to the tissues; and yet in such cases it is that, in the absence of a better remedy, the eminent Graves recommends the use of antim. et potass. tart. in large doses, with opium.

Few practitioners have the temerity to recommend the use of antimony at a juncture in disease so critical and dangerous as the one referred to. In such cases musk was formerly resorted to, and more recently, camphor and chloroform, taken internally, have been used; but there is reason to believe that the bromide of potassium, in combination, is more safe, effective, and salutary. He says in combination, for it doubtless acts partly by its own powers and partly by modifying the action of opiates and antispasmodics, the different articles aiding each other in the production of the good result.

He cites cases showing that the effect of the remedy was obvious and triumphant. The bromide of potassium was given in \mathcal{D} j. doses, combined with sulph. morph. gr. $\frac{1}{2}$, in solution, on three different occasions, in each case at intervals of three hours.

Medical News.

"BOSCH."—The public was somewhat alarmed at the revelations made a few days since in the Thames Police-court, when it transpired that a Dutch butter factory exists in Glaucaus-street, Bromley, where "Real Dorset" is said to be made from suet. Messrs. Haas and Co.'s have contradicted the fact in a letter to the daily papers, stating, in effect, that theirs is a suet refinery, and not a butter factory. Whether the unfortunate factory upon which the odium has accidentally fallen deserves it or not we do not care to say—we are content to accept Messrs. Haas and Co.'s explanation. This, however, does not dispel the wretched fact that in London there are several manufacturers of what is dignified with the name of butter by the public, but which is known in the trade as "bosch." We regret that this is the case, but it is of no use blinking the fact. It is perhaps the work of that inexorable master—the law of supply and demand. There is a large section of the public who will have butter at a less price than any dairyman or woman could produce it for, so the manufacturer of bosch steps in and fills the gap.—*The Grocer*

NOTICES TO CORRESPONDENTS.

AN OLD SUBSCRIBER.—The side position is most common. A many-tailed bandage which can be gradually tightened by assistants prevents syncope. The skin may be divided by a bistoury before plunging in the trocar.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I see by a letter from Dr. W. W. Leeper, of Loughgall, in your issue of the 29th of September, that he also has been successful in the treatment of diphtheria by the use of carbolic acid. I attended two children, brother and sister, more than a year ago, suffering from the same disease, and used the same carbolic acid lotion (one to twenty), with the same result. I forget the internal treatment, but believe it was potass. chlor., and as much nourishment as their poor parents could afford to give them.

Yours truly,

ALLEN E. DOUGLAS, M.D.

Warrenpoint, Oct. 18, 1869.

"OXYGEN FOR INHALATION."

SIR,—In the present week's issue of the MEDICAL PRESS AND CIRCULAR, I observe a short note from Dr. Luther, requesting some information regarding oxygen inhalation. He will, I believe, find all the information which he can require in my work "On the Action, Use, and Value of Oxygen," published at Churchill and Sons, Barth and Co., 21 Duke street, Bloomsbury, supply the most reliable, but the most expensive apparatus with condensed gas. By writing to that firm, he could learn their terms.

As I suggested in my work, however, Dr. Luther might easily extemporise an apparatus, if the cost of Barth and Co.'s method be a serious drawback.

I am, Sir, yours faithfully,

61 Harley street, W.

Introductory Lecture

TO THE COURSE ON

GENERAL PATHOLOGY.

By WILLIAM R. SANDERS, B.L., M.D.,

Professor of General Pathology in the University of Edinburgh.

GENTLEMEN,—Before proceeding to the special subject of this lecture, it is proper that I should, in accordance with established custom, refer to the career of my immediate predecessor. After holding the chair of general pathology for twenty-seven years, Professor Henderson has retired in consequence of ill health. You are all aware that Dr. Henderson held peculiar views in medicine. It is not my intention particularly to refer to these. My purpose is to render justice to Dr. Henderson's scientific labours, which are in some danger of being overlooked or forgotten. After graduating in medicine in this University in 1831, Dr. Henderson entered on the practice of his profession, and was at an unusually early period appointed physician to the Fever Hospital, and afterwards to the Royal Infirmary. In this position he soon distinguished himself as an original observer of disease. In 1835 to 1837 the results of his clinical study appeared in certain remarkable contributions on the subject of disease of the heart and larger blood-vessels. In these papers he recorded the earliest notice of the murmur of efflux in a case of sacculated aortic aneurism, and he was the first to point out, as a distinctive sign of aortic regurgitation, that the radial pulse followed that of the heart by a longer interval than usual. These points of diagnosis indicate acute powers of investigating disease. By far the more important original observations which he made, however, had reference to the discrimination of the typhus and relapsing fevers in the epidemic of 1843. Dr. Henderson was the first who adduced evidence to prove that the one of these fevers never communicated the other; and that an attack of the one afforded no immunity from an attack of the other. The conclusion therefore was that these two fevers,

usually confounded, were distinct, and were due to different poisons. The importance of recognising separate types of fever, in a sanitary as well as a medical point of view, is immense; and Dr. Henderson's fame will rest chiefly on these researches. A later memoir by Dr. Henderson, in conjunction with the late Professor John Reid, of St. Andrews, on the typhus and typhoid fevers, displays similar qualities of accurate observation. Advancing with the science of the day, Dr. Henderson, as early as 1841, employed the microscope for pathological research on the anatomy of the lung in pneumonia, on molluscum contagiosum, &c. Without further detailing his papers, I may refer, finally, to his clinical lectures in 1842—44, which prove that at that period he had acquired a position of eminence as a clinical teacher. Indeed, I have frequently heard it stated by those who had been his contemporaries or his students, that while a hospital physician his powers of diagnosis were held in the highest estimation. In 1842 Dr. Henderson was appointed to the chair of general pathology in this University. Shortly afterwards a memorable change occurred in his medical opinions, which resulted in his adoption of the tenets and practice of homœopathy. In consequence of this, his connection with the Royal Infirmary as clinical physician was dissolved in 1844; but he retained his chair in the University. After this period he still continued diligently to increase his stores of medical erudition, which were very extensive; but I am not aware that he made any important contribution to medical discovery. We cannot but regard that change of views as peculiarly unfortunate which interrupted a scientific career so full of promise.

Pathology is—or professes to be—the science of disease. It investigates the causes, the nature, and the laws, of morbid action. But, it may be asked, is a science of disease really possible? In view of the notorious discrepancies of medical opinion, can we pretend to have attained the certainty of scientific truth? Does pathology rest in any fixed basis, or are we deluding ourselves with mere formulas accepted to-day, rejected to-morrow? In reply to the objections, I think it may be maintained that although only in modern, or indeed in recent, times has it any pretensions to be called an exact science, yet at all

periods of its history, medicine has been cultivated to some extent scientifically, and has afforded the materials, which have gradually accumulated, for a true pathology. The certainty or uncertainty of pathological doctrines, the progress or retardation of the science, have depended entirely on the methods by which it has been cultivated, the means of investigation at its command, and on the aid which the accessory sciences of anatomy, physiology, and chemistry have been able to afford it. The utter failure of speculative pathology, and the success of the methods of observation and induction, are nowhere more conspicuous than in the history of medicine. Alluding to the steps by which pathology had progressed as a science, to the degree of certainty it had attained, and its place and value in medical science and practice, the lecturer stated that the earliest study of disease was necessarily by means of the symptoms, and the earliest pathology rested, therefore, on that foundation only; but it was quite clear that scientific certainty could not be arrived at from the study of symptoms alone. The observation of symptoms required immense skill, and even to the most expert they were often unsatisfactory or fallacious. It was certain that had symptoms been the only source of knowledge, many diseases must have remained undiscovered, and the intimate nature of all of them unknown. Even now it was by trusting to symptoms alone that persons were so apt to be deceived both as to the nature of disease and the influence of remedies. The only key to the interpretation of symptoms, and the only method by which pathology could be advanced, obviously consisted in a knowledge of the structure and functions of the body. A natural repugnance and prejudice, however, long retarded the progress of these sciences; but gradually, after their cultivation in the sixteenth and seventeenth centuries, facts of morbid or pathological anatomy began to accumulate—at first somewhat out of curiosity, but gradually assuming importance. The first great work in which morbid anatomy was made the foundation of certainty in medicine appeared only a century ago. In his old age, Morgagni published the experience of his own lifetime, and that of his immediate predecessors, in a series of cases, in which the symptoms during life were carefully recorded with reference to the anatomical changes observed by dissection. The treatise on the "Seats and Causes of Disease as investigated by Anatomy" marked the date of commencement of the modern science of pathology. The modern science of pathology is chiefly based, therefore, upon morbid anatomy. Noticing the various stages of the progress of the science, and mentioning that the first occupant of the chair of general pathology, Dr. John Thomson, taught the subject of morbid anatomy as part of his course, and employed Carswell to make that splendid collection of pathological drawings, part of which is now in possession of the University, the lecturer proceeded to refer to the position and influence of morbid anatomy on pathology, and stated that it had given certainty to pathology and medicine, and promoted their progress, first, by contributing to render more certain the diagnosis in the detection and discrimination of diseases previously known; second, by serving to distinguish diseases previously confounded together—for example, typhus and typhoid fevers; third, by the discovery of new diseases; and lastly, by establishing the anatomical history of diseased structures throughout their whole progress, from their original elements to their termination in organisation or destruction. In conjunction with morbid anatomy, chemistry had rendered distinguished services to pathology, especially in the investigation of the fluids—the blood and excretions; whilst physiology also, and the department of experimental and comparative pathology, had greatly increased our knowledge of the science. "I have thus endeavoured to show how, apart from any great speculations, or wide generalisations, pathology has progressed by extending the field and improving the methods of observation. We have now nearly as complete a scientific knowledge of

diseased as we have of natural processes; both are alike founded on the study of structure and of function; both are subject to the same general laws of organisation—physiology and pathology; healthy anatomy and morbid anatomy are all branches of one common science of life. From a consideration and comparison of the pathology of special diseases, may be deduced certain general principles which constitute general pathology. In this relation, however, it must be again noted, as appears from the whole history of pathology, that the science possesses few great generalisations. In the department of morbid anatomy or histology, we have indeed certain theories of organisation—the cell theory with its various modifications—these are certain laws of action of morbid poisons, of periodicity, of self-limitation or disease, &c. But on the whole, the principles of pathology are of limited application; in this respect resembling those of the allied science of physiology. These principles, however, are of great importance, from their immediate bearing upon practice, and from the certainty they give to medicine. Indeed, one of the greatest of advantages derived from pathology is the recognition that disease, in place of being obscure and variable as to be incapable of scientific treatment, is in reality subject to the same definite laws as the healthy body. Hitherto I have said little of that department of pathology which treats of the causes of disease—viz., etiology—for it is quite obvious that the causation of diseases could not be fully ascertained till they were accurately observed and discriminated from each other. So long, for example, as typhus and enteric fevers were undistinguished, there was little chance of arriving at any accurate data as to their causation. In recent years, owing to the great progress of medical science, the department of etiology has begun to assume a great, indeed a national importance. I need only refer to the large amount of accurate investigation which is now brought to bear in tracing to their origin the outbreaks of epidemics of fever, cholera, &c. Under the able direction of Mr. Simon, scientific medical men are continually engaged in these and similar inquiries; and the annual reports of the medical officer of the Privy Council are a rich mine of etiological information. The Epidemiological and other societies also furnish valuable contributions. The influence of climate is also now scientifically investigated; and you are all familiar with the important discussions in regard to ventilation and the germ theory of the diffusion of disease, &c. There is, in fact, no branch of pathology of more extensive importance than etiology; and the necessity will soon be admitted of having in all districts, which at present we find only in large towns, officers of health, or practitioners of "State medicine," who shall furnish accurate information of the existence of epidemics or of extensive sickness among the people, so that preventive or protective measures may at once be put in force. We have now to meet the great practical question, Of what use is pathology for the treatment of disease—i.e., for therapeutics? For although it might be shown to be of great importance to know with scientific accuracy the nature of disease, even independently of treatment, yet unquestionably the true aim of the physician is the cure of disease. In this respect the uses of pathology have ever been—1st, to show that many diseases are self-limited, and of themselves tend to cure if not interfered with; 2d, by establishing the natural course of disease as a standard to show the inefficiency of many reputed modes of treatment, and thus prevent useless and injurious medication; 3d, to analyse morbid phenomena so as to present to the therapist the indications for treatment. Therapeutics has hitherto been mostly cultivated as an art—i.e., empirically—doubtless with many useful results, as even in our own day the recent discoveries of useful medicines prove; but the effects of medicines are now being investigated on scientific principles in accordance with the minute anatomical and physiological analysis of the present day. Medicines are found to act specially on certain textures, or certain elements of textures; while, on the

other hand, pathology teaches that diseased processes are also limited in their action to certain textures and elements of textures. There is, therefore, every reason to believe that pathology and therapeutics will be brought more closely into conjunction; and that we shall obtain a scientific system of therapeutics more certain and more powerful than has hitherto been possible. Such a result would be indeed the triumph of the medical art. Having now sketched the outlines of the science of pathology, what parts of it ought more specially to receive our attention? I have no hesitation in answering that morbid anatomy is the department which ought to be made the foundation of the teaching from this chair. And it is my intention to carry out that view. It will be possible to illustrate the lectures with the large and valuable collection of drawings by Carswell to which I before alluded; there are also the ample resources of the University Museum; and, finally, arrangements are in progress by which fresh specimens of diseased structure will be demonstrated before you. With these and the other opportunities which our medical school presents, there is no reason to doubt that the subject of morbid anatomy will receive the careful study which we have already seen its importance requires. If I can succeed in explaining clearly to you the anatomy and physiology of disease, in relation to symptoms and causes, then you will be specially prepared to profit by your courses of practice of medicine and clinical medicine. For pathology studies diseases analytically, or, where synthetically, in the synthesis of anatomical or physiological connection; but practical and clinical medicine view disease in a different aspect—viz., in the complex combination of symptoms which nature presents, a complexity which renders the accurate observation of individual cases of serious disease a study of great and peculiar difficulty. Under these circumstances you will find an accurate acquaintance with pathology yield you invaluable assistance, giving a precision and certainty to your knowledge of disease which would otherwise be unattainable.

UNIVERSITY OF EDINBURGH.

PROFESSOR LISTER'S OPENING LECTURE.

ON Monday, 8th Nov., Mr. Lister, the recently-appointed Professor of Clinical Surgery at the University, delivered his opening lecture in the Chemistry Class-room. There was a large attendance of students. Professor Lister was accompanied to the rostrum by Principal Sir A. Grant, Bart., Professors Christison, Bennett, Balfour, Crum Brown, Wilson, and Muirhead, ex-Professor Syme, Dr. Morehead, Deputy-Inspector of Hospitals, Dr. Bryce, and other gentlemen. Ex-Professor Syme, on entering the room, met with a most enthusiastic reception.

Professor LISTER, in the outset of his discourse, said that while on the one hand he could not but feel proud to have the honour of occupying a Chair which, without disparagement to others, must be allowed to have been during the last thirty-six years one of the most influential, if not in itself the most important, in connection with their Medical School—(applause)—on the other hand the exultation he felt was dashed by the thought that the circumstance which had led to his promotion was the retirement of him to whom the lustre of the Edinburgh Chair of Clinical Surgery had been from first to last entirely due. (Applause.) It was well known that that gentleman had made the place, not the place him; and although in his presence he must not say all that he otherwise would, he could not refrain from expressing his conviction that, whether regarded as a scientific and practical surgeon or as an editor of those principles which he had done more than all other men in this century to establish, Mr. Syme had been without a rival in the world. (Applause.) Hence in addition to the grief which he felt in common with them all in the cause of their late Professor's resigna-

tion of the Chair he had so long adorned, he was oppressed with a humbling sense of his own insufficiency—he was weakness compared with his predecessor's strength of mind and purpose—he was utter inability to fill his predecessor's place. But leaving these personal considerations, let them turn to the subject that lay before them. Clinical surgery was, strictly speaking, surgery at the bedside—surgery illustrated by cases in hospital, as distinguished from surgery taught systematically in the class before him. The importance of bedside study could not be over-estimated; it was the very keystone, without which all the educational structure, being merely preparatory, would be absolutely useless. It was to surgery what dissection was to anatomy—it conferred a familiar acquaintance with the nature of disease, and the instinctive knowledge of the proper treatment, without which a man, however accomplished, would be utterly unfit to practise the profession. But how, it might be asked, could a course of lectures be delivered on that principle? Would it be possible to take a class of the size of his present audience to an hospital ward and profitably teach them there? To do this would certainly be impossible. Remarks made at the bedside were doubtless highly valuable to those who heard them. It was impossible to take a large class to the bedside; but it was possible, in most instances, to bring the patient before the class collected in the operating theatre, where they could all see the salient features of the case, and hear not only the remarks of the teacher, but the patient's own account of his symptoms, and the treatment then and there put in practice; or, if it was thought desirable to defer the operation till another day, they were prepared to watch the steps with interest and profit, after having heard the principles of the procedure fully discussed. Such a course of instruction was thoroughly clinical, and, if rightly conducted, possessed a vividness of interest and permanence of impression peculiar to itself. Having witnessed the advantages of the system when in Edinburgh, he had followed it out in Glasgow, and would continue to pursue it here. But invaluable as such lectures might be made, students were not to suppose that attendance on them would do all that was necessary. They must not only see diseases and their treatment by others, but by acting as dressers and house-surgeons in hospitals, they must obtain personal experience in the management of cases; and no man should assume the responsibilities of practice without having availed himself largely of the opportunities presented in Edinburgh Infirmary or some similar institution. The learned Professor devoted the remainder of his hour to an exposition of the germ theory of putrefaction, as the basis of the antiseptic system of treatment.

Original Communications.

ERGOT OF RYE AS A THERAPEUTIC AGENT.

By J. WARING CURRAN, L.K. and Q.C.P.I., &c.

ALTHOUGH the chief uses of ergot of rye are, for the most part, confined to those affections of the uterus over which it seems to exercise a specific action, I have been induced to give extensive trial of the drug in other complaints; and as I have found most satisfactory results from its administration, the following paper has been written in the hope that ergot of rye may be more frequently exhibited as a medicine, and that the practitioner may be reminded, in it he has a most potent therapeutic agent of reliable efficacy in other diseases apart from those affecting the uterus.

In Parturition.—The physiological action of ergot of rye upon the parturient uterus in exciting contractions of the unstriated muscular fibre is familiar to all, and the constant pains which it induces so characteristically differing from genuine labour pains. This action is entirely produced through the ganglionic nervous system by

affecting the muscular coats of the blood-vessels, and thus diminishing their calibre. We are told by Dr. Brown-Séquard, as the result of a series of experiments made by himself, that the blood-vessels of the pia-mater of a dog under its influence become smaller, and that the reflex action of the spinal cord was diminished to a great extent.

In three-fourths of the labours attended by myself, I have exhibited ergot with most salutary results. I have never observed any ill effects from it, when judiciously given, to either mother or child. I never attempt it unless the os is dilated and dilatable; and primipara cases, if the pelvic development be natural, and the os be not rigid, never prevent my giving it. The cases we read of, and lecturers have told us about its destructive effects upon the mother, and its poisonous properties to the child, experience teaches me, must have been cases where ergot was improperly given.

I have used extensively the liquid extract prepared by the action of ether and spirit upon powdered ergot, and the tincture too; but on neither have I the least reliance. Some time ago I was sent to assist a medical gentleman; upon my arrival I found the child's head in the vagina, and complete inertia; the gentleman in attendance told me he had given the liquid extract in large and repeated doses without any appreciable therapeutic action. I immediately prepared a fresh infusion—the preparation I invariably employ—added to it some borax; in twenty minutes its action commenced, and within an hour the child was born. I do not say that in such a case the short forceps would not have done equally well; but people, as a rule, have, in private practice, so great a hatred to instrumental deliveries, and are so apt to attribute every little trivial subsequent complaint to their use, that I have not used the forceps as frequently as formerly.

When studying midwifery, some years ago, at the Rotundo Lying-in Hospital, Dublin, I painfully noticed—and the observation has made no little impression upon me—that the students and embryonic midwives were compelled to allow poor women to continue in labour, hour after hour, until nearly exhausted, because the rules of the institution forbade their interference, unless an over-fed and morose female superintendent was awaked and consulted. The educated student, revolting at such consultations, allowed the case to linger in preference. As I now reflect, I have not a particle of hesitation in saying that many of those confinements might have been safely and expeditiously concluded hours previously, had the best informed and senior student been permitted to prescribe a dose of ergot. To keep a woman five minutes in labour longer than she might be is an unnecessary and a great cruelty. The freshly prepared infusion with borax will demonstrate its action in twenty to twenty-five minutes, or earlier if the anterior os be gently irritated with the forefinger. So far as ergot is related to the accoucheur, I should feel disappointed arriving at the bedside of a parturient woman without it. I write not inconsiderately making this remark, for I thoroughly deprecate the exhibition of any drug given indiscriminately and recklessly, and can thoroughly comprehend the issue of a case of distorted pelvis, or rigid os (when antimomial wine is requisite) where any could be found foolish and inexperienced enough to prescribe ergot.

Flooding after Labour I have never failed arresting by a full dose of infusion of ergot, at the same time lowering the patient's head, elevating the pelvis, and firmly applying the padded binder. I have observed in the practice of others that plugging the vagina had in several instances to be superseded by a full dose of ergot of rye, and that with the desired effect.

Mænorragia is a term now so inaptly applied to the varied forms of uterine hæmorrhage, requiring different treatment, that I purpose devoting a paper to this subject alone, and to the effect which heat along the dorso-lumbar region produces by inducing hyperæmia of the vaso-

motor nerve centres related to the uterus, and through the increased currents along the nerves, causing contraction of the uterine vessels, and thus arresting mænorragia; but here I must confine myself to those varieties of uterine hæmorrhage best cured by the ergot of rye. What I am pleased to call the *strumous abortive predisposition*, met with in patients of a scrofulous habit, who have become very frequently impregnated, who suffer from constitutional debility, from leucorrhœa when the mænorragia has exhausted itself, or when arrested by treatment, demands the exhibition of ergot when the hæmorrhage is present, which it rarely fails to command. Mænorragia from obstructive cardiac disease at either the mitral or aortic orifices, congesting the pelvic viscera, that associated with a diseased portal system, that consequent upon a scorbutic state of the system, and genuine mænorragia—*i.e.*, an increase of the catamenia continuing for an unnaturally lengthened period and returning before the time calculated upon, without organic lesion, are the forms or varieties of mænorragia to be benefited, to be checked and cured by the freshly prepared infusion of ergot and borax. Mænorragias dependent upon ulceration of the os uteri, due to the existence of polypoid growths, or owing to the presence of malignant excrescences, or the effect of retroflexion of the uterus, do not come among the category of cases to be affected beneficially and permanently by ergot of rye, although I have used the drug for the purpose of pressing down the growth of a polypus to be snared, a malignant or an ulcerated surface to be cauterised.

Amenorrhœa occurring in the plethoric is best treated for a few days with strong salines, aloetic purgatives, or medicines which act upon and increase the circulation of the large intestines, and then closely followed by two-ounce doses twice a day of the infusion of ergot, prepared according to the British Pharmacopœia. Amenorrhœa in those who have only *changed* a few times, and in those of tender years, and amenorrhœa of chloritic women, should have citrate of iron, spirits of ammonia, and tincture of nux vomica administered for three weeks in full doses, and the fourth week be ordered hip-baths, and from one ounce to an ounce and a half doses of the infusion of ergot thrice daily.

In these cases, as in the parturient, vomiting is sometimes induced, being the direct effect of the drug upon the muscular coat of the stomach. Accordingly, to prevent this, I direct the albumen of an egg or some gruel to be partaken of before the medicine, and this with good results invariably.

Hæmoptysis I have frequently arrested for a time with ergot, with good effect in the commencement of phthisis; but I should not be disposed to prescribe it lest vomiting should be set up in the hæmoptysis which sometimes accompanies the advanced stages of pulmonary consumption.

Hæmaturia.—I have found great benefits from the tonic effects of ergot upon the blood-vessels, in causing a diminution of their calibre, and arresting hæmorrhage from the kidney. I can safely say that its effects are superior to either turpentine or the vegetable acids in this complaint, and that the same observation applies to the tonic effect it produces on the muscular fibre of the bladder in those cases of general atony which come under our notice, and for which so little permanent good can be done.

Constipation of the Paralytic is strikingly remedied, when the most powerful cathartics fail, by occasional doses of ergot, which sensibly diminish the amount of blood present in the spinal cord and its membranes, give tone to the muscular fibre of the bowels, and thus propel the fecal matter to the rectum.

Fatty Degeneration of the Heart.—I have had and still have two patients suffering from this complaint, who are very materially assisted by occasional doses of ergot. I can only compare its tonic virtues to that of carbonate of ammonia, but as experience is limited I cannot write emphatically.

As an *Injection in Gleet* I believe I have been the first to use the infusion of ergot in this complaint, and I have not yet failed. I employ the Pharmacopœia infusion, and direct its being injected three and four times in the day. I observe the tonic power it imparts to the urethra.

When the injection is thrown along the urethra, I direct the meatus urinarius to be firmly pressed against the nozzle of the syringe, so that the ergot may lie for five minutes in the urethra; for experiment has taught microscopically that the first effect of ergot locally applied to a raw surface, is, 1stly, to increase the circulation; 2ndly, to suspend the circulation; 3rdly, the circulation recovers itself, is still disturbed, and irregular, or spasmodic, showing that the contraction and relaxation of the muscular coats of the arteries are subservient to the will of the ergot, hence, undue contraction producing gangrene. These series of phenomena upon the blood-vessels of the urethra, at all events set up healthy action and cure a foul disease.

I hope this paper may have the effect of bringing more prominently forward one of our most valuable drugs, that in the diseases I mention the practitioner in extensive practice may be induced to test its value and give us the result of his experience, for it is only by combining results that accuracy is established. To the point: an accomplished surgeon, at my suggestion, has employed infusion of ergot as an injection in a case of chronic catarrh of the bladder. The reports of the case are valuable, but they are not corroborated by other cases, hence my delicacy in alluding to what another will publish; for in other similar cases its tonic virtues may not prove as effectual.

P.S.—The inconvenience and trouble of preparing a fresh infusion of ergot on every occasion—the tincture and extract of the Pharmacopœia being unreliable—combined with the fact that the patient knows the nature of the loathsome dose about being administered, has induced my consulting Mr. Edward Long, of the eminent firm of Hamilton, Long, and Co., of Dublin, regarding the great want of a new and reliable preparation. I am happy to state that in a few weeks a great desideratum will be accomplished, and that the Profession will have an opportunity of testing the power of a new preparation, which will have the advantages of being *sweet, concentrated, and permanent*; the ergot, being first exhausted with glycerine, which is strained off, the residuum is digested in spirit, and then evaporated to the consistence of syrup. The two solutions are joined, so that we get all that is soluble in water—infusion, and all that is soluble in spirit—extract, tincture, &c.; but a more full and practical description of the method of this new preparation of ergot I retain for a future contribution, when the utility and therapeutic power of the preparation is established.

Hospital Reports.

ROYAL FREE HOSPITAL.

In a recent visit to the Royal Free Hospital, we found that Mr. J. Hill had two cases of stricture under his care, on which he had employed the forcible dilatation plan of Mr. Holt with perfect success. Mr. Hill expressed his very high opinion of this operation, and mentioned that he had already operated successfully by its means on nearly thirty cases of severe stricture. The details of the cases he will probably publish shortly. Of course, he added, there are cases not suited for the operation; and occasionally, though very rarely, some untoward accidents may arise in careless hands; but the operation must be looked upon as one of the greatest improvements in modern surgery.

We observed in one of the wards a case of stricture, accompanied by fistula, and destruction of a portion of the urethra, just anterior to the scrotum. The patient, a man

about thirty, was in a deplorable condition on entering the hospital. No catheter could be passed, and, shortly after he came in, there was some infiltration of urine or abscess upwards, and, consequent upon this, a slight faecal fistula in the lower part of the abdomen, which lasted some time. By patient attention Mr. Hill first contrived to introduce a catheter into the bladder, and subsequently, by means of a plastic operation, he attempted to unite the divided portions of the urethra. The appearance of the patient was greatly ameliorated, and Mr. Hill is in hopes to effect a comparative cure in this most complicated case.

The venereal wards in the upper storey of this hospital have been for some time untenanted, owing to loss of funds occasioned by the outcry raised against the hospital in one of the Medical Journals. It is hoped, however, soon to open them again to those unfortunate patients who stand so much in need of shelter and medical care, both on their own account and quite as much in the interests of public hygiene.

A young man, a smith, was brought into hospital by a policeman for the following accident:—A large bar of iron had suddenly fallen upon his right leg below the knee, crushing the bone and soft parts so suddenly as to render it imperative to perform amputation above the knee. This operation was performed by Mr. Hill by means of a flap, containing only integument off the front of the thigh. The man made an excellent recovery, and the stump was entirely free from all conical appearance. We saw the patient the day after the operation. He was quite calm, and employed in reading the newspaper. Such hopefulness gave him, of course, an admirable chance of escaping from some of the sequelæ of such severe operations as amputations of the thigh in hospitals have been found to be.

UNIVERSITY COLLEGE HOSPITAL.

THE patient operated on by Mr. Erichsen for aneurism in the thigh about Poupart's ligament, by tying the artery in the pelvis, is doing well, and has a good appetite, and appears in a fair way towards recovery. On Wednesday Mr. Erichsen operated on the man with popliteal aneurism, whose case had resisted all attempts to cure it by means of compression on the artery in its course along the thigh for three or four weeks past. The operator made the usual incision along the front of the thigh, and, carefully separating the artery from its surroundings, he tied the artery without in any way injuring the vein. It is somewhat remarkable that two cases of such a rare disease as aneurism should have thus come under Mr. Erichsen's care at once.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.

ON Tuesday, the 9th inst., we saw the following cases in the ophthalmoscopic room. The first case was under the care of Mr. Couper. A man, about forty years of age, complained of having, about a week before the visit, suddenly lost vision in the left eye to a great extent. In the ophthalmoscopic examination a muddiness was observed in the vitreous, owing, Mr. Couper thought, to the bursting of some small vessel of the retina into the vitreous.

The second case was one of great dimness of vision in a shoemaker about the age of fifty. In this case ophthalmoscopic examination of both eyes presented an appearance as if there were a whiteness and want of vascularity of the retina: atrophy. The man said he was a very hard smoker, and had smoked from morning to night for years, as much, perhaps, as an ounce a day. Such cases are, of course, the more important that they point to the possibility of slightly diminishing the number of cases of amaurosis, by abandoning the habit of tobacco-smoking to a great extent. But a German gentleman of great oculistic experience informed us that in Germany such cases of tobacco amaurosis were far from being so common as he found them in London.

ROYAL VICTORIA HOSPITAL, NETLEY.

Abscess of the Liver; Discharging outwardly.

THE following case is the fourth of abscess of the liver, under Professor Maclean. We have already published the three former ones of this series:—

Sergeant Buchanan, aged thirty-seven; Department of Public Works, Bengal; seventeen years' service, of which ten were spent in India. With the exception of a few attacks of ague this man's health was good; his occupation involved great exposure to the sun. On the 7th of November, 1868, he had a heavy day's work, and was exposed all day to a hot sun; he was much exhausted, and slept in a thorough draught of air during a cold night; awoke next morning with a sharp pain in the right side, with fever, and was confined to bed for six weeks. Finally an abscess of the liver pointed in the mesial line, two inches below the ensiform cartilage, and discharged a large quantity of purulent matter of a dark red colour. As the discharge continued for a long time in India, injections of nitrate of silver, and afterwards of tincture of iodine, were used; and as his health was much impaired, he was sent home. On arrival at Netley on the 17th December, the liver was found to extend downwards $2\frac{1}{2}$ inches below the false ribs, the opening was discharging freely, and continued to do so for four months after admission, notwithstanding the use of the antiseptic dressing and great attention to his general health. The discharge has now almost ceased, and in a few days the patient will be discharged.

The site of this abscess was favourable, it is in the position that gives the largest number of recoveries, when the abscess is discharged through the abdominal parietes.

As Dr. Maclean has elsewhere remarked, in the few cases of hepatic abscess that have discharged externally presenting themselves at Netley, the majority have the cicatrix where it was in this case—that is, in the epigastric region.

◆

SPECIAL REPORT
ON
STUDENTS' TEXT BOOKS.

(Prepared expressly for the MEDICAL PRESS AND CIRCULAR,
by Professors in Schools of Medicine.)

No. VI.

BEFORE the student can put in practice all he learns as to the treatment of diseases he must make himself intimately acquainted with the remedies he may have to employ. *Materia Medica*, therefore, occupies a very important place in the curriculum, and to the study of it he must bring his knowledge of botany, chemistry, and some other subjects which have already been considered. Of course, he need not want for text-books, as they abound on every subject,—and *Materia Medica* and *Therapeutics* go, as it were, hand in hand in this matter. Churchill has two Manuals on these subjects. The *Materia Medica* originally projected by Royle is very good, and the names of the medicines in several languages render it useful to a large number. The “*Manual of Therapeutics*” in the same series is by Dr. Waring, whose labours on the Indian Pharmacopœia we have already commended. Both these works maintain their reputation as good condensed books. A little while ago we reviewed a new work on “*Therapeutics*” by Dr. Sydney Ringer, published by Mr. Lewis, of Gower-street. The success of the book, we believe, is amply justifying our favourable notice. We have always felt, however, that on so large a subject the student really requires something more than the most excellent of Manuals. In the work of his life his principal care will be

to select remedies and watch their influence, and he will, therefore, gladly avail himself of many monographs as well as of much larger books than on most subjects. The late Dr. Pereira's work was an invaluable encyclopædia for both student and practitioner, containing the fruit of a laborious life. It is rich in information, and unapproached by anything else in the language. Its only fault was, it was too bulky. If we had not effected so many changes by the new Pharmacopœia it would yet be a library in itself of all required in *Materia Medica*. Those who do not mind the trouble involved in referring to the changes thus brought about will still find it a mine well worth digging, and though out of print we believe a second-hand copy is often to be met with at Mr. Lewis's. The abridgment of this book we do not recommend. If a new work were to be projected we should like to see Pereira with only such changes as time has made indispensable.

The want of a work above the ordinary hand-book, but less bulky than the encyclopædic Pereira, was supplied by the late Dr. Neligan's “*Medicines, their Uses and Mode of Administration*,” and a very popular work it was, worthy in every way of the repute of its amiable and accomplished author. It exactly filled the position we have marked out as desirable. For this reason we congratulate Messrs. Fannin and Co. upon having brought out successive editions of the work under the care of one who had the advantage of working jointly with the author before his lamented decease.

We have before us, and have lately been re-examining, the seventh edition of “*Neligan's Medicines*,” edited by Professor Rawdon Macnamara. It is thoroughly brought down by the learned editor to the present day. It includes a complete conspectus of the new British Pharmacopœia, with which every paragraph has been brought into accord, and may be regarded as the joint result of the long labours of both Neligan and Macnamara. In a single, large, thick volume, there is brought together far more information than could be expected in a mere hand-book, and as the perusal of such works is, after all, much more agreeable than that of the most condensed Manuals, we can heartily commend it to the notice of all who would like to have the best book on the subject. Its price being a little higher than most Manuals is more than compensated by the fact that it will really replace two, one on “*Materia Medica*,” and the other on “*Therapeutics*.” Though fully adapted to the new Pharmacopœia, it is not confined to it, three or four hundred other medicines being included—and yet the B. P. are readily distinguished. The work is arranged in a series of twenty chapters, on the classes of agents—antacids, astringents, tonics, &c.—each class having a chapter. The twenty-first chapter is devoted to waters, and includes a very brief notice of the principal mineral waters and their composition. Of course, this will not suffice to enable the reader to choose a mineral course in a difficult case, but it will serve well to refer to as to the composition of those waters mostly prescribed. Chapter 22 is devoted to supplementary agents, of which fifty-five are described. Chapter 23, on the administration of medicines, is brief, to the point, and contains excellent advice as to the writing of scientifically constructed prescriptions. Would that many would thoroughly master the principles here taught! A very pithy reply is offered to those who, disgusted with the long formulæ for heterogeneous medleys, have gone to the other extreme, and refused to combine any two remedies.

Simplicity is certainly to be commended, but the work before us shows that this is not altogether incompatible with taking advantage of more than a single drug at a time. A poscological table follows, and very complete it is. We were pleased to find four columns in place of the ordinary two. One of the additional columns gives the dose for a child one year old, the other the best form of administration.

After this we have a series of formulæ. These are followed by a classification of the chief plants used in medicine. The volume concludes with a most copious index, by means of which ready reference is offered to any subject treated of. We have said enough to show that the student who buys Macnamara's *Neligan* will possess ample materials for reading up *Materia Medica* and *Therapeutics* for his examination, while the practitioner who makes the same purchase will obtain a most reliable guide in the selection of remedies and the modes of administering them under the varying circumstances of every day practice.

We now propose to close our Special Reports on Students' Text Books by remarking very briefly on one or two that were not included in the proper place in consequence of the gentlemen to whom they were entrusted being unable to finish them in time, and one or two others that have reached us since the articles on the subjects to which they relate were issued.

"Exercises in Practical Chemistry," by A. G. V. Harcourt and H. G. Madan (Oxford: Clarendon Press; London: Macmillan). This is an invaluable work for those who are beginning to learn practically the beautiful science of chemistry. It may be regarded as a companion volume to Roscoe's "Lessons," which we have already noticed. If chemistry were practically taught in our schools this would be the text-book. It is admirably adapted for those who begin chemistry before their strictly professional studies. It is not specially adapted for medical work, but may advantageously precede physiological chemistry.

"A Guide to the Examination of the Urine," by J. W. Legg, M.D. (London: H. K. Lewis). This is a concise guide to the clinical clerk, and may even be carried to the bedside to refer to. With one or two exceptions it seems to be as well done as could be expected. We hope the author may have an opportunity for revising it by the speedy call for a new edition.

"Abstracts of Surgical Principles," by Thomas Annandale, F.R.S., and F.R.C.S. (MacLachlan and Stewart). If a great book is a great evil a little one is no little good. There is no more useful product of teaching than an exact and carefully arranged abstract that seems but the syllabus of a course of lectures. Such is Mr. Annandale's, which comes before us in four distinct parts. These abstracts were, in fact, originally printed for the students of Mr. Annandale's Class of Systematic Surgery, and they are so well done that we are very glad they are now within the reach of all. Part I. is a small 8vo pamphlet of 37 pages, and includes inflammation, suppuration, abscess, sinus and fistula, mortification, ulceration, and ulcers. Part II. is an uniform pamphlet of 66 pages, devoted to tumours. Part III. is 36 pages on dislocation; and Part IV. contains 57 pages on fractures. These abstracts are of the highest value for the first year's lectures—far better than the most careful notes that could be taken by a student. In the second

year we would advise a student to have them bound, with ruled paper interleaved, and by additions of notes make his own text-book.

"Phthisis and the Stethoscope," by R. P. Cotton, M.D. (Churchill). This little work has reached a fourth edition, and, though not a complete guide to auscultation, is a very efficient one so far as it professes to go—that is to say, in relation to the dire disease to which it is mostly confined. The student who desires to master auscultation should diligently work in the wards. "The Physical Diagnosis of Diseases of the Heart and Lungs," by Dr. Herbert Davies, the senior physician to the London Hospital, should be thoroughly mastered. Dr. Cockle's translation of Weber is an excellent handbook of auscultation, and now published at a reduced price by Lewis.

"The Diseases of Children," by Fleetwood Churchill, M.D. (Fannin), is uniform with the author's other Manuals already reviewed in this series, and it would be difficult to point out any other work more adapted to the student and young practitioner, although the subject is a favourite one. That Dr. Fleetwood Churchill's name is a sufficient guarantee for the contents of such a book is well illustrated by the fact that his "Diseases of Children" originated in a request from America to write one. Maunsell and Evanson's work has been a standard one for a whole generation, and therefore needs no word from us.

Some time ago we had the opportunity of reviewing Dr. Graily Hewitt's admirable treatise on "Diseases of Women," so that we need not now repeat our commendation of that truly valuable book. We desire, however, to draw attention to a series of outlines for pictorial diagnosis of these diseases, which the learned Professor of University College had lithographed for the purpose of clinical instruction, and which are published by Mr. Lewis. They are sure to be useful, though we think the author would have done well to give a page or two of letterpress to explain their use. Full explanations might easily be given, and we hope that Dr. Hewitt will thus make them useful to others than his own students.

Dr. Fenwick, of the London Hospital, has just brought out "The Student's Guide to Medical Diagnosis" (Churchill's). It appears to us to supply a real want, and the execution of the design is as well nigh perfect as could be believed. Instead of a bulky, heavy volume, Dr. Fenwick has given the student one that he may always carry with him in a side pocket. It is illustrated with a good number of woodcuts, and supplied with a diagram and carbon paper for recording cases pictorially.

There will soon be a new edition, for such a compendious guide cannot fail to please students. We only beg the author not to increase the size, a temptation into which so many fall. If he must add more, let him confine himself to engravings. Perhaps, however, he might give two pages on skin diseases, of which the diagnosis often puzzles students.

Our last remark brings us to the one subject that remains. The most complete treatise on Diseases of the Skin is the large volume of Erasmus Wilson, with which there is nothing that can compare. The same may be said of the plates, but such luxuries are not for all students.

The best Manual that has come under our notice for these Reports is that of Dr. Neligan, edited by Dr. Belcher, and which will be found fully equal to all the requirements of students and young practitioners. It is a work that has stood its ground, that was worthy the reputation

of its author, and the high position of which has been maintained by its learned editor.

In closing these Reports the Editors of the *MEDICAL PRESS AND CIRCULAR* would express a hope that they may be found useful. Much care has been bestowed upon them, and, once more, the teachers in our Hospitals and Schools who have so kindly helped in the work are warmly thanked for their assistance.

EXTERN MATERNITIES AND LYING-IN HOSPITALS.

A REPLY TO CRITICISMS ON A COMMUNICATION TO THE DUBLIN OBSTETRICAL SOCIETY.

By *EVORY KENNEDY, M.D., F.K.Q.C.P.*

(Concluded from page 366.)

ANOTHER charge, or rather an insinuated imputation, was made even more absurd in its nature, in a few excited words, that said but little but implied a great deal, by Dr. Sinclair, on the third night's discussion.

This gentleman introduced the name of the Prime Minister, with a suggestive insinuation that he was going to deal destructively with the hospitals of this city. No doubt, Sir, in admitting that Mr. Gladstone's acquirements are as varied, and his information as extensive as conceivable, yet I may affirm, without assuming any knowledge of State secrets, or committing myself in their divulgence, that he knows just about as much of this discussion or its objects as of that important question that engrossed the attention of the three tailors of Tooley street. Sir, I believe in my heart Mr. Gladstone's aspirations, wishes, and intentions are, as all may know who will be at the pains to inquire, to benefit the poor of this country in every manner that his enlarged mind, great experience, and devotion to sanitary improvements so peculiarly befitted him to do. Sanitarians, at least, must agree that fortunately for Ireland, the power, the knowledge, and the will to exercise them in the right manner are combined in one man, at this moment, and that man is one who has taken the improvement of the sick and impotent in this country seriously to heart. Fortunately for us, as Irishmen and physicians, the practically benevolent pursuits to which Mr. Gladstone and his family have always been devoted have well prepared him to deal with the improvement of the medical charities of this country.

And, still more fortunate for us in Ireland, the manner in which his efforts have been so ably seconded by the partner of his cares (a title nobly earned by her whose exertions to benefit the London charities have rendered the name of Gladstone, as that of Nightingale, a household word with the benevolent). Sir, the medical men and citizens of Dublin have a right to know the fact, as this name has been so invidiously, and, I may add, so injudiciously, introduced into a purely scientific discussion: that the same anxiety to improve and extend our Dublin charities that has so well succeeded in London, prevails in that benevolent, large-hearted mind, and, unless frustrated in its exertions to accomplish its object, I doubt not the same success will attend them.

If, after the experiences, the facts, and the reasonings, and the reliable statistics that have been produced, there be still amongst my hearers and readers more than one man who denies that our large lying-in hospitals cannot, and ought not, to be improved in their rates of mortality, and that, even upon the showing of those gentlemen who have taken an ad-

verse line in the discussion, I should like to see him and hear him say so boldly. If there be not, then there is at least one point upon which every man in this Society, and, I might add, every man who knows anything of the subject, out of it, must agree—that is, that a necessity exists for lessening the death-rates in lying-in hospitals. The means of doing that is entirely another question, and one upon which there may be as many different opinions as there are individuals present. Taking it for granted, then, that a necessity exists for an improvement, it may be further affirmed that every one of the recusants who carried, as one of them pugnaciously remarked, "war to the knife" against my inquiry—the hospital physicians and their congeners who admitted so many of my propositions, and confirmed the real basis of my arguments—and the general listeners, including the sons of Korah, who have exhibited such patience and zeal in sitting out the nine nights' discussion, I say, it may be affirmed that each one of my hearers and readers who has arrived at the above conclusion, and who, as far as in him lies, does not endeavour to correct it, is assisting in sustaining that death-rate. Do not deceive yourselves, gentlemen. He is not merely in the position of an accessory after the fact; he is from this day out an accessory before the fact. And what is the fact? It is the taking away of life—precious life, a gift that none of us can restore.

The law recognizes two descriptions of responsibility: that by commission and that by omission; and culpability attaches as well to the first as to the last. I now say, and say with deliberation, that every one of us—who possesses the power, by act, word, or deed, of preventing the unnecessary loss of life, and who exercises his influence against that prevention, or omits to exercise for it, is morally in one or other of these positions.

Following, Sir, the example of my commentators, I might have been perfectly justified, in a discussion of this nature, in turning to account the artifices of oratory. Like them, I might have attempted bathos and perhaps accomplished travesty.

I might have appealed to them to use their own language, not mine, not to give over "these poor women to die in the proportion of 3 to 1 that ought to die in their hospitals." I might have besought them as parents, as husbands, to throw their shield over those doomed to become motherless and bereaved.

I might have attempted to arouse their feelings by depicting the mother led in tears from her humble but happy home to the hospital to endure the pangs of labour, cheered with the confident hope of a speedy release in health and strength—a hope, alas! how bitterly to be disappointed!!!

I might harass them by attempting to depict that death-bed scene, and its consequences, with which, alas! I am but too familiar.

The strong, hopeful woman; but yesterday, grasped by the unrelenting hand of death, in a silent, lonely, strange chamber, separated from her friends, and tended by the hand of the hireling stranger, unsoothed, unsoled by those tender attentions of her family, that deprive even death itself of half its terrors.

I might have changed the scene, and depicted the shrouded victim stretched on the table of the ghastly charnel-house, until her husband and surviving relatives attend to convey the remains of her they loved, and parted with so hopefully a few hours before, to her last resting place.

But who could attempt to calculate or depict the consequences of this bereavement to that sorrowing family? A father obliged to neglect his motherless family in the discharge of his daily duty. The children deprived of their guide—now Arabs on the street, swelling the huge catalogue of crime. The males, perhaps, ending as felons—the females, as worse.

But, Sir, neither my inclinations nor my respect for my

audience approve of such a course, in a strictly practical inquiry, "*non tali auxilio nec defensoribus istis tempus eget.*" Nay, I might have appealed to the gentlemen who oppose this attempt at lessening the mortality by an improved arrangement of our lying-in institutions, and begged them not to rest satisfied that 1 death in 45 deliveries proves to us that matters are "tending to render the hospital as healthy as one could almost desire."

I will, however, appeal to them in the language of the Patriarch pleading for the cities of the plain, and say:—Peradventure we might find a way of saving 20 more women in every thousand. Shall we not do it? Or even if, peradventure, we might save 10 more in every thousand—let us do it. Or to the recusants who object to the expense or inconvenience, with a comparatively small improvement, resulting to the hospitals, such as the modified improvements in St. Petersburg, Vienna, and Paris, we might add—Peradventure we might even find a way of saving 5 lives out of every thousand—let us do it.

It is doubtful whether those gentlemen, my critics, whom I have not specially answered may not be more dissatisfied with my breach than my observance of this mark of respect. Should such be the case, I can only apologise to them in the words of Napoleon I. in bidding farewell to his army on leaving France for Elba:—"Soldiers, would that I could embrace you all! As this is impossible, I salute your generals."

Sir, it remains for me now merely to express my apologies for the imperfect manner in which I have executed this great, this painful duty, and to thank you for the patience with which you have borne with me.

Nine nights have been devoted to this important investigation; the amount of mortality in our great hospitals has been brought to light, and the means of preventing this have been elucidated. It rests with us now to apply our knowledge—and that without delay—for, in the words of the American poet—

"Man-like it is to fall into sin,
Fiend-like it is to dwell therein."

ASSOCIATION OF MEDICAL OFFICERS.

PREVENTION OF SCARLET FEVER.

THE continued prevalence of scarlet fever in London has been often alluded to by ourselves, our contemporaries, and the Registrar-General. The last-named recently said in his Report—"The Medical Officers of Health will no doubt endeavour to suggest some practical means of preventing its further extension."

In consequence of this the Association has forwarded the following Memorandum to the Registrar-General. The great importance of the subject to the public health is a sufficient reason for giving it a place in our columns:—

"It is quite possible to check scarlet fever, if adequate means be taken to destroy the emanations of the sick, so that they shall not infect the healthy. For this purpose the sick must be separated, either by putting them into rooms apart, or by sending them out to a sick house, or, which is better, by removing the healthy to another house. The infecting matter of the disease resides in the excretions of the mouth, throat, and lungs, of the bowels and kidneys, of the skin, and of the suppurating surfaces common towards the close of the disease. Disinfection should be applied assiduously to the mouth, nose, and throat, as each case may require, by gargling, swabbing, or syringing with a teaspoonful of Condy's Fluid to a pint of water; the excreta of the bowels and kidneys should be well dosed with strong carbohc acid before they leave the bedside; the air of the sick room should be occasionally freshened by dispersing Condy's Fluid (diluted as above) by means of a vaporizer, and the doorway should be hung with a sheet well sprinkled with carbohc acid, so that there may be no mixing of tainted air with that of the body of the house. It can do no harm to oil the skin during the height of the fever, but

what is of real consequence is the persevering use of warm soapy baths so soon as the patient can take them, and through the convalescence till the skin has done peeling and the throat and nose are healed. All handkerchiefs, towels, and linen before leaving the room should be steeped in boiling water, containing a teaspoonful of chloride of soda or of Condy's liquid to a pint; and when the disease is over, the bedding and clothing of the patient and his attendants, all floors, walls, and ceilings, and the surface of all furniture on which infectious matter may have settled, should be scraped or cleaned with a disinfectant and fumigated. Moreover, disinfecting fluids (as carbohc acid) should be poured freely after the slops from the sick room into the closets, sinks, drains, and sewers, and into every place around the house where decaying organic matter can be harboured.

"The persons attending on the sick should wear glazed or smooth dresses by preference; they should often wash their hands, especially before eating, and should mix as little as possible with the family.

"For fumigating infected rooms and their contents nothing is better than sulphur. A quarter of a pound of brimstone, broken into small pieces, should be put into an iron dish (or the lid of an iron saucepan turned upside down), supported by a pair of tongs over a bucket of water. The chimney and other openings are then closed with paper pasted on, and a shovelful of live coals is put upon the brimstone. The door is then quickly shut, the crevices covered with paper and paste, and the room kept close for five or six hours. After this a thorough cleansing should be effected; everything washable should be washed, and all other things be cleansed by proper means.

"Fumigation of clothes, &c., may be easily carried out on a small scale by burning a sufficient quantity of brimstone matches.

"Provided there be no unsuspected drain, sewer, gully, water-closet, pipe, or cistern, or other source whence the inmates receive fresh infection, scarlet fever can be and is daily arrested in private houses by the above means carried out in detail: but only by persons having space, wealth, intelligence, and the wish to save life. It is far otherwise in the crowded houses of the poor, where the healthy are mixed with the sick and even with the dead.

"Public hygienic measures are then necessary, and the following are the measures which the Medical Officers of Health recommend:—

"MEASURES OF PUBLIC HYGIENE AND THE PRESENT IMPEDIMENTS TO THEIR ADOPTION.

"1. Information should be diffused through every family by printed bills as to the contagiousness of scarlet fever and the mode of preventing it. Expense has hitherto prevented the adoption of this measure.

"2. Every case of scarlet fever, and especially every first case, should be immediately reported to the sanitary authority. At present this is not done. There is no provision by which cases of infectious disease, even in Poor Law and public practice, shall be made known to the Medical Officers of Health. In some districts, by an act of courtesy, information is forwarded at more or less prolonged intervals, and so, usually, at a late period of the illness. It is only when death occurs that the health officers with certainty hear of the occurrence, and by that time (often a week or ten days after death) the contagion may have spread more or less extensively. They never hear officially of private cases; it is held to be the interest of all parties to conceal their occurrence. Without early and ample information it is impossible to put in force the provisions of the Sanitary Act directing the disinfection of houses, &c., and forbidding the exposure of diseased persons and articles.

"3. Every case so reported should be immediately visited by the Medical Officer of Health or his skilled assistant, who should see that all proper precautions are in preparation. But even with full and early information, adequate precautions could only be superintended by the devotion of all the time of the Health Officer to public work, for which the sanitary authorities have made no provision, and by the aid of a staff of assistants such as was given to few of them even during the cholera epidemic.

"4. The streets and courts and the yards of infected houses should be watered with a disinfectant solution, such as of carbohc acid. Such a proposal could not be made to a metropolitan vestry with any chance of compliance. The expense

and the dread of panic would be obstacles. This proceeding has hitherto, therefore, been limited to severely infected streets and courts.

"5. Public day and Sunday schools in an infected district should be authoritatively closed. The out-patient rooms of hospitals and dispensaries are even more dangerous than schools. It should be a punishable offence to send a child to any day-school, public or private, from a house or family in which fever exists. There is, however, no power or authority for this.

"6. Sufficient hospital accommodation should be provided for the poor, with arrangements at each hospital for the disinfection of the person and clothing of the patient on his discharge. No sufficient hospital accommodation as yet exists.

"7. Where it appears to the Medical Officer of Health necessary that the sick person should be removed he should enforce the removal, certainly in any case where the sick is under no medical care, or is being treated at the public expense. Very limited powers of this kind are at present conferred by the 26th section of the Sanitary Act, 1866, and these are only applicable after considerable dangerous delay. This section is practically useless.

"8. An appropriate carriage should be provided in every district for the conveyance of the sick to the hospital. At present public cabs are still largely used because few local authorities in London have provided appropriate carriages, as they are empowered to do by the 24th section of the Sanitary Act, and sometimes because the sick refuse to use them.

"9. The Sanitary Act (sections 24 and 38), as it relates to the use and disinfection of public carriages for the conveyance of persons with infectious diseases, should be enforced; this is not done.

"10. There should be in every district one or more proper mortuary houses for the reception of the dead of any class of society, and removal thereto should be capable of being enforced where necessary. There are many of the districts of the metropolis in which the local sanitary authorities have not yet provided the mortuary house, which they are empowered to provide by the 27th section of the Sanitary Act; even when it has been provided the limitations imposed by that section render the statute practically valueless. In all cases a packet of Macdougall's or of Calvert's disinfecting powder should be strewn over the body before the coffin lid is screwed down, which should be done as quickly as possible.

"11. The sanitary authorities should provide such a staff of assistants or labourers and such appliances as may be necessary to carry out the disinfection of houses, clothing, bedding, &c., where people are too poor or ignorant to be trusted with the work, and also proper means of destroying certain things by fire. The 23d section of the Sanitary Act, empowering local authorities to provide means of disinfection, has, it is believed, up to the present moment been entirely ignored in the metropolis, not even a 'proper place' having been provided where disinfection may be carried out. Houses are often now very inefficiently disinfected for the lack of a proper staff of persons to carry out the work.

"12. There should be arrangements by which articles of clothing, bedding, &c., destroyed by order of the Medical Officers of Health may either be replaced or paid for. At times when the Diseases Prevention Act is not in operation by order of the Privy Council no such arrangements can be made.

"13. During the disinfection of a house or apartment, or when the sick person cannot be moved, it is necessary to remove the healthy; for this there should be one or more houses of refuge provided, in which poor families may be temporarily lodged, and with means of disinfecting the persons and clothing of those removed. A house of refuge is a thing at the present time utterly unknown to the sanitary arrangements of the metropolis.

"14. The Diseases Prevention Act should be put into operation by order of the Privy Council on any severe outbreak of scarlet fever in London, or at times when from seasons or cyclical period it is probable that the disease will spread extensively. Practically, this otherwise invaluable Act is a dead letter, except on certain occasions when an unusual disease prevails in this country, such as an epidemic of cholera.

"15. The services of public nurses to superintend the administration of nourishment and medicine and the disinfection of discharges would be invaluable. One bad case of scarlet fever furnishes quite occupation enough for one woman.

"16. The Medical Officers of Health desire to put in force the

lodging-house clauses of the Sanitary Act, 1866, sec. 35, which, by restricting the number of inmates, and by enforcing periodic cleansing of the homes of the poor, might in some degree limit zymotic diseases."

MEDICAL REFORM.

DANGERS AHEAD!

WE have taken pains to keep our readers *au courant* with the march of ideas on all the branches of Medical Reform. We have foreshadowed one Bill that is likely to be brought in. We have from time to time urged everyone to employ his influence in compelling attention to the subject. Only last week we gave as complete a report as we could obtain of the debate at the Medical Club, on the memorial of the ten thousand. Still it is no time to cease our efforts. There are other vague notions abroad; strange proposals are likely to be made, and, as we have said, our Medical Reformers may have as much to do in defending as in attacking institutions.

It is no secret that there is a class of men who are so enamoured of iconoclastic notions that they would gladly sacrifice any institution for the sake of producing a *tabula rasa*. To them perfection is a blank, and all their efforts are directed towards abolishing something. There are few such in our Profession. Greatly as we pride ourselves on recent advances, there is veneration for the past amongst us, and as a body we do not desire to overturn anything that serves a good purpose. Still a few have been smitten with this destructive impulse, and some one or two seem to have found a vehicle for the expression of their opinions in the *Medical Mirror*. That monthly sheet, which has lately passed into new hands, appears to have abandoned the spirited programme of its former conductor, to place itself unreservedly at the disposition of those who would carry free trade in physic to such an extent that the whole community would be left to the tender mercies of quackery,

and the Profession as a body thrown more open than it is in America, whence the wails of our educated brethren reach us across the broad Atlantic, and should warn us of what would be the consequence of such extreme notions.

Happily, we need not fear the adoption of any such ideas, and may therefore pass on to consider the opposite danger. It is whispered that an attempt may be made at reform which would hand over the Profession, bound hand and foot, to a Government Committee. Hints have been dropped in various quarters that the Medical Council, not being a representative body, and not agreeing to become so, might give place to a small body of five or six persons, nominated by the Privy Council, responsible only to that department, and endowed with authority over the whole Profession, and all that relates to it. With a Liberal Ministry we may be sure such an unmitigated scheme of centralization will not be entertained without hesitation, even though proposed by persons of influence. The Profession would regard anyone who sanctioned such a surrender of its rights as an odious traitor. To barter away the liberty of 20,000 professional men, who only ask to be allowed to regulate their own affairs, would disgrace the purest despotism. How, then, can it find favour in a free country, with a free press? Nothing but the most criminal treachery could propose to set up a worse oligarchy than the many with which we have been afflicted, and the depths of professional apathy might well be stirred by the bare mention of such a scheme.

What the Profession has asked is such a reform of the Council as would make it a representative body. Why should anyone be offended at so just a demand? We have asked for bread, a stone will not satisfy us; we cry for fish, offer us not a serpent.

SCARLET FEVER.

THE continued prevalence of scarlet fever in the Metropolis and many other places has, at length, caused the Medical Department of the Privy Council to issue a paper entitled, "Precautions against Scarlatina." From its tenour it would be difficult to say whether it is intended for the guidance of the sanitary authorities, or for the instruction of the public. If the former be its object, it will prove of comparatively little use, because it is hardly more than an echo of Dr. Budd's precautionary directions against scarlet fever which were published early in the present year, and consequently have been long familiar to sanitary officers. If the latter be its purpose, it will be found to be too vague, and to leave too much discretion in the choice of the measures to be adopted. For instance, there is not much use in cautioning the public against drinking impure water; what was required under this head was, information relative to the means of recognizing foul water, which frequently does not betray its dangerous condition to the eye nor to the nose. Again, the recommendation that "in the room and on the person of the patient every practicable disinfection should be effected without delay," is much too general. Precise directions ought to have been given for disinfecting the sick room and the person of the patient. This was the more necessary because there are many poor persons who will not be willing to conform to the advice tendered them in the official "precautions," and refuse to have their sick transferred to hospitals, even if there were sufficient hospital accommodation for all, and will prefer at all risks to have them tended, even when a separate room is out of the question. And, if some of the writers on hospitalism are worthy of credence, who can blame them?

In like manner, whether they be addressed to the sani-

tary authorities or to the general public, the official directions might have been expected to say something definite as to their respective efficacy of the "two great classes of chemical disinfectants," by which is no doubt meant those that act by oxidation, and those of the anti-septic kind. Disinfectants are now universally admitted to be so essentially necessary for successfully combating infection as to have rendered it incumbent on the Government Department, which presides over sanitary matters, to institute such comparative practical trials as would suffice to decide the question. It is acknowledged in the "Precautions" under consideration, that "these two systems do not combine well with one another," which is equivalent to saying that they are diametrically opposed.

We could have wished, moreover, to see some other substance than chlorine named as the representative of the oxidizing class of disinfectants. Ozone would appear to us better to represent the latter. Being oxygen itself in the active state, it is a direct oxidizer, whereas chlorine acts only as an indirect oxidizing agent. In quantity sufficient to procure aerial disinfection, ozone can be employed in inhabited rooms, whereas chlorine cannot. We have no hesitation in saying that the State Sanitary Department is much to blame for allowing the advantages derivable from ozone to remain up to the present time unascertained. With the means at their disposal they might long ago have set this question at rest. More than ten years back, the late Professor George Wilson, of Edinburgh, made the following remarks in reference to this subject:—"No one who has experimented on ozone will deny its potency. I refer to it here, because there are so many reasons for believing it to be the great natural disinfectant that I cannot avoid looking hopefully to it as destined to prove our disinfectant *par excellence*." If this view of Wilson's be correct, we are allowing to remain overlooked and neglected the very agent which is calculated to subdue infectious and contagious influences.

RELAPSING FEVER AND VAGRANCY.

In the Memorandum on the Re-appearance of Relapsing Fever in London, issued on Nov. 11th, by the Medical Officer of Her Majesty's Privy Council, is contained a brief account of the rise and progress of this disease, from July 4th, 1868, when the first well-marked case was admitted into the London Fever Hospital, under the care of Dr. Murchison.

From inquiries made by Dr. Murchison concerning the disease abroad, it appeared that relapsing fever, along with typhus, had been epidemically prevalent in the Province of East Russia, lying on the north of Poland, since the end of 1867; and, further, that relapsing fever had prevailed extensively in Berlin during 1868; and at St. Petersburg the disease was epidemic as early as 1865.

It was in May of the present year that the disease became fully pronounced in London; in October 123 fresh cases were received at the London Fever Hospital, and on the 10th instant we learn that there were in the wards of that institution no fewer than 138 cases, so that the wards were overflowing.

People are beginning now to know the disease whose outbreak has been thus sketched by the name of "Famine Fever," and while those who are well off and well fed may comfort themselves that a disease having for its cause starvation and bad living, may not just yet venture to intrude into their comfortable homes, they must yet remember that a famine fever is not a disease to be cured merely by physic, physicians, and hospitals. Very necessary will it be this winter that all reasonable relief should be afforded to assist the starving poor, and so enable them to withstand the inroads of famine fever, and to enable those attacked to make a good convalescence; for thus, not only will the present epidemic be mitigated, but the calamity to be apprehended in the form of an outbreak of true typhus, so often consequent on relapsing fever, may be averted.

Tramps and vagrants herding together in the casual wards of the workhouses seem to be the chief media for the diffusion of the relapsing fever among the community, and the dimensions to which vagrancy has now attained are truly astounding. In 1863 the number of vagrants relieved in the casual wards of the Mile-End Union was not 3,000; for the last three years the annual number has exceeded 18,000.

Though it is very certain there will always be idle people who will not work, and who prefer the life of a vagrant to any other; yet among such a number as 18,000 as compared with 3,000, there must be a very great proportion who are brought into this evil plight by the present depression of trade, want of work, and expense of living.

What exact proportion in 18,000 vagrants those who are such from necessity and misfortune bear to those who are such from choice, it would be interesting to discover. We believe that a large number might be classed as persons whose first misfortune was that of not knowing when they were well off; that is to say, people who, while living in comfort, though not, perhaps, in abundance, in the country, have sought to better themselves by coming to London, or to some other large overcrowded city. Young men with no encumbrance may do well enough coming to one of the great towns; but the case is likely to be very different with the man who brings his wife and half a dozen small children, with no definite prospects or plans, into one of the great towns.

Thus it is that overcrowding and overstocking the labour market with a supply greatly in excess of the demand brings poverty and destitution; epidemic and endemic disease soon seize the opportunity and establish their reign; poor rates rise, and all classes complain loudly enough.

The remedial measures must be for the parish authorities to use every legitimate means to discourage idleness and stimulate to self-reliance. Lazy vagabonds from the country, who are known and treated as such there, must find that in London their characters are discerned and dealt with; and if they can work and won't work they must be made to work. Emigration to the colonies should moreover be encouraged in every possible way; the earth is big enough for all, if folk will but avail themselves of its resources.

Lastly, with respect to the rise of epidemics, be they famine fever, or any other form of wide-spreading malady, we need only say, let such be met with the energy, decision, and promptitude with which the Privy Council and their Health Officer appear to be encountering the present outbreak of relapsing fever. We know that Heaven helps those who will help themselves.

SCOTLAND.

FEMALE MEDICAL STUDENTS.

FIVE ladies have availed themselves of the right accorded to them by the General Council of the University of Edinburgh, and have matriculated as students in the Faculty of Medicine. An innovation so novel, so contrary to what are conceived to be British tastes and prejudices, as the admission of ladies to the privileges which our Universities confer, must necessarily interfere, more or less, with its immediate success. The organization of a new system is always a work of time and patience; but its supporters have usually the elements of success in their own hands, if they advance with a caution proportionate to the extent and nature of the difficulties they are seeking to overcome. The female students of Edinburgh have good reason to triumph in their success and in the successful exertions of their friends on their behalf; but in this there is a danger

which is already beginning to appear;—of their aspiring, with unwise haste to privileges which the Council are not yet prepared to concede to them. It has been said that the University might have “gone a step further and carried the admission of women to the ordinary courses of lectures, instead of permitting the very needless and unmeaning compromise which requires special courses to be delivered to the women separately.” Considering the various interests which are involved in this question of extended privilege, it is greatly to be feared, that if the matter is pressed by our ingenuous female students, and their unpardonably impulsive male friends, their cause may be damaged to a much more serious extent than is their position at present by the University regulations. There are other interests, besides those of its female students, which the University has to consider; and the first of these are the interests, feelings, and prejudices of the Professors, and these deserve the most respectful consideration. They have been recognized by the Senatus and University Court in adopting the third resolution recommended by the Faculty of Medicine:—“That the Medical Faculty be allowed to have classes for ladies, but that no Professor shall be compelled to give such course of lectures.” The occupants of the Medical Chairs were elected to discharge duties the nature of which they perfectly understood when appointed. It is in their option, with consent of the University Court, to add to these duties, but it would be clearly unfair in the Court to compel them to do so. Again, there are many more with minds so constituted who would feel it impossible to discourse to *ladies* upon certain topics embraced in a medical course, who have no difficulty in doing so to a class of men. In attempting to answer this objection, it is absurd to employ the argument that the treatment of *every* scientific subject must be delicate, for the most modest might occupy a seat in any of our medical class-rooms, without having a blush called up by any want of delicacy on the part of the lecturer in the treatment of his subject. It is a feeling which it is impossible for the possessor of it ruthlessly to overcome, for it is one which education has only strengthened, and which is fostered by the constitution of society. In a mixed class of males and females these feelings would be outraged beyond endurance; in a purely female class the difficulty might be got rid of, by avoiding or merely glancing at those subjects which are felt to be painful. But the person for whom this alternative might be suggested is of all others the man most likely to reject it: he would refuse to epitomise the subject which he professes, which is perfect only in so far as it is complete, and he would feel as if guilty of an act unbecoming in an honourable gentleman if he pocketed even a minimum fee for work so imperfectly done.

Of the prejudices entertained by individual Professors, we shall only remark that we believe them to be respectable and worthy of respect. But there is another class of men who have prejudices also; and it is a matter of very little importance of what nature they are, whether they are worthy or unworthy, respectable or otherwise, for the prejudices of students always make themselves felt, and in a way not usually pleasant. Students, to say the least, are somewhat peculiar, medical students proverbially so; and although it is a habit with some who fail to convince by force of reasoning, to endeavour by a process of stamping out to annihilate the prejudices of their weaker brethren, we fear the experiment in the present case would be some-

what dangerous, at all events it will require a considerably greater amount of force than is possessed by the five pairs of feet of the combined female students, to stamp out the prejudices of five hundred medical students of the opposite sex.

Other reasons for caution in pressing for greater advantages for the female student might be adduced, but it would be tedious to do so; and we would conclude, therefore, with suggesting two words as being admirably fitted to serve as a motto for the ladies' gentlemen friends—*'festina lente.'*

ROYAL MEDICAL SOCIETY OF EDINBURGH.

THE hundred and thirty-second session of this society was opened on Friday evening, November 5th, with an address by Dr. Alexander Wood. There was a large attendance of members. A society so flourishing, and, in some respects so unique, is worthy of a passing notice. Founded in the year 1737 by six students attending the University, for the purpose of discussing subjects of professional interest, it has acquired at this date an influence and a prestige hardly surpassed by any other in the Kingdom. Numbering among its members some of the most distinguished living graduates of the University of Edinburgh,—Christison, Stokes, Ferguson, Carpenter, Sharpey, Morehead, Simpson, Bennett, Murchison, &c., &c., it has become classic from the lustre which surrounds the memories of such men as Oliver Goldsmith, Akenside, Gregorys, Monros, Bright, Allison, Goodsir, and a host of other revered names, all members of the society. It is now, as it was at its foundation, a Students' Society, and in this it possesses singular advantages. With a library of 16,000 volumes, constantly receiving fresh addition, a reading-room and museum, where private studies may be pursued, and descriptive information brought to the test of practical observation, it affords to the student, by the weekly debates which occupy its attention, an opportunity of cultivating those talents for public address, which is so desirable, but which, apart from a society of this kind, it is impossible for the student of medicine to acquire; and, above all, it gives a stimulus to the acquisition of knowledge, beyond the beaten track of class-room reading, which will prevent, more than anything else, the student degenerating into the routine practitioner.

PROPOSED NEW EDINBURGH INFIRMARY ON THE GROUNDS OF GEORGE WATSON'S HOSPITAL.

A PUBLIC meeting is to be held on Friday, the 19th inst., for the purpose of eliciting from the subscribers to the new building their views regarding the propriety of the managers of the Infirmary applying to Parliament for power to carry out the following resolutions:—1. That the new Infirmary shall afford accommodation for surgical as well as medical patients; and, 2, that the new Infirmary shall be built on the grounds of George Watson's Hospital. From what has been already ascertained of the views of the subscribers, it is almost certain that the meeting will be nearly unanimous in favour of the application.

MR. SYME.

THE meeting held on Wednesday last for the purpose of organising a testimonial to Mr. Syme, was a spontaneous tribute of respect to that great man, which it is as impossible as it would be unbecoming to attempt to characterize. In retiring from the more active duties of his professional life, Mr. Syme enjoys the rare privilege of knowing that his intense earnestness in the work of his life is acknowledged as being a triumphant success by those who are best able to appreciate its usefulness, and that in generations to come, his name must continue, as now, a familiar sound, so long as the University he adorned exists.

GREENOCK.

OUTBREAK OF SMALL-POX.—We are given to understand that small-pox has become very prevalent in the lower districts, and we have heard of a case where no less than seven patients were removed from one house by the local authority and sent to the Infirmary. This shows the necessity of the provisions of the Vaccination Act being enforced with the utmost rigour.—*Greenock Advertiser.*

MEDICAL APPOINTMENT.—At a meeting of the Parochial Board of Cannongate, Edinburgh, Mr. W. B. Alexander, surgeon, was appointed medical officer of the parish, in room of Dr. Linton, resigned.

Notes on Current Topics.

Registration of Disease.

THE Epidemiological Society, the Social Science Association, the Officers of Health, the Medical Society of London, and the St. Andrew's Medical Association, all seem agreed that a registration of disease would be of great service. A deputation last week waited on Mr. Goschen, and laid before him a very simple plan for securing a return of such diseases as are observed by the Poor-law Medical Officers. It is clear that very little extra work would thereby be entailed on these gentlemen; and, of course, for that they should receive some remuneration. It was proposed to place the returns of disease in the hands of the Registrar-General, and that would be much better than leaving their publication to the Poor-law Board. The machinery for tabulating and distributing such statistics is in operation at Somerset House. In fact, the additional information is just what is wanted to render the Registrar-General's Returns more useful.

The Black Hole of St. Pancras.

THAT the deceased died from "the mortal effects of an effusion of serum on the brain;" and the jury do further say that the death "was accelerated by overcrowding and want of ventilation in St. Pancras Infirmary." That is substantially the verdict returned by a jury presided over by Dr. Lankester, not in a single case, but in several, and is an apt commentary on our boasted humanitarian principles in this year of Grace, 1869. Tender-hearted as we are, no wonder we lavish our sentimentality on "habitual criminals," insist on the sacred human rights of inhabitants of our jails, and tremble at the thought of inflicting punishment on felons. One patient seems to have died after a single night in the black hole dignified by the name of ward. Others survived longer. The conclusion of the inquests has been adjourned to next Monday; but an extract from the evidence submitted will be enough to nauseate our readers. Hear what a Vice-President of the London College of Surgeons, and hospital surgeon of the highest standing, has to say. Mr. Solly, F.R.S., said he had gone round all the wards. As to No. 11, he declared he "had been in a good many foul places, but never in all his life went into any room which stunk so beastly as that ward." Further on, he said all the wards "were foul and offensive." Again, in reply to the Coroner, he said, "the place was badly ven-

tilated and overcrowded, and had such an effect upon me that after I left the ward I was obliged to stop to get fresh air before proceeding, so much was I overpowered by the stench." Evidence was further tendered to the effect that what fresh air could enter came through the water-closet. It is not worth our while to repeat all the loathsome details that have been brought to light. Enough has been stated to show that the black hole of St. Pancras is no inappropriate name for a ward in a London Workhouse Infirmary. Some people have been strongly objecting to inquests on the paupers who die in our workhouses. It is well known that the able Coroner for Middlesex thinks that an inquest should be held in every case. The revelations that have been made will go farther than anything else to convert to Dr. Lankester's opinion those who were hesitating about accepting it.

Certificates of Death.

In the late inquests objection was made to one being held, as the medical officer had given a certificate of death, and he, as we think unwisely, looked upon the proceeding as a personal offence. No medical man need fear that Dr. Lankester would put any slight upon him. On the other hand, the medical officer in question drew upon himself a retort as to his having given the certificate without sufficient care, and without seeing that the patient was actually dead. We have before referred to this point, and we do so again now because the practice is of every day occurrence. We cannot blame the medical man in question. No one makes a formal inspection of a body to see that death has actually taken place. The certificate of death requires revision, for it makes the attendant say that the patient died on a certain date, whereas he only knows so, as a rule, by the report of some one else. The Registrar-General would do well to alter the wording.

The Preference of Paupers for Vitiated Air.

The atmosphere of Ward No. 24 in the St. Pancras Workhouse must indeed be something quite overpowering; for we learn from the evidence that came before Dr. Lankester at the inquiry on November 10th, that "the ward was very close, and the patients complained very much." Now, there are few things to which paupers object more than to fresh air; and we well remember, many years ago, when shown over the, at that time, well-ordered wards of the St. Pancras Workhouse, having our attention drawn by the medical officer to the ingenious way in which the inmates of the wards stopped up every crevice, even to the keyholes of the doors, with paper, so as to preclude ventilation as much as possible. We have often reflected on what peculiarity there might be in the organisation of paupers to render them so averse to purity of atmosphere. It is not as if anything were taken away from them perceptibly for which they received no compensation, unless, perhaps, they feel instinctively that in a pure atmosphere their tissues are more rapidly oxydized, and their hunger augmented, and thus Nature is stealing an unfair march upon them.

However this may be, we may be sure that an atmosphere of which this large class of the community complain of as being too close and oppressive for them to exist in with comfort, must be something very much out of the common in the way of badness.

Treatment of Epilepsy by M. Bost, at Les Asiles de La Force, Dordogne, France.

AMONG the excellent asylums established by M. Bost, at La Force, Dordogne, in the south-west of France, is one that is devoted entirely to the use of epileptic girls; and although the indefatigable Superintendent, M. John Bost, in his modest little report does not give us exact columns of figures denoting cases admitted, with exact number relieved, cured, or dead, still his data are sufficient to illustrate one or two significant points.

Thus, he tells us (page 42 of the report), that with several of his epileptics the fits have disappeared for two, three, or four years; yet, when they came in, they had several fits on the same day. To what remedy are we to attribute these satisfactory results? Simply to no medicine at all. M. Bost gives them no physic; but diet is, as we learn, carefully regulated according to the necessities of each. One patient is fed up with meat and wine, another is treated by withholding both of these. In each case highly satisfactory results appear to follow.

Medical and Chirurgical Society.

ON Tuesday, the 9th inst., the first meeting of the Session of this Society was opened by two communications on the subject of pneumonia, one from Dr. Heale, of Leeds, the other from Dr. Waters, of Liverpool. The first of the two papers, that by Dr. Heale, attempted to prove that the inflammation in pneumonia was caused by an exudation into the interstitial substance between the air cells, which air cells, the author contended, as far as we could make out, were supplied with their blood from the bronchial artery. The debate on this point was neither luminous nor very instructive. It seemed to us that no one in the room quite knew what the author of the paper meant. The paper by Dr. Waters was very practical. It consisted of the concise narration of a certain number of cases of pneumonia, uncomplicated, as far as possible, with diathetical conditions of the system, with the treatment which the author had pursued at the Northern Hospital. The success of the treatment appeared to have been great, although the author of the paper rejected from his treatment the calomel and opium, the tartar emetic and much of the purgation of the heroic school. The only agents which Dr. Waters appeared to set any store by were alcoholic stimulants and blisters. The rest of his therapeutics may be described as nursing and hygienics. The speakers following after the paper were Dr. Sanderson, who observed, what all persons of experience must have felt, that all statistics concerning such a disease were apt to be fallacious, because the cases of pneumonia met with in practice so seldom are one like the other, some commencing after bronchitis and being lobular, others coming on at once and becoming lobar. One or two gentlemen objected to the use of blisters in pneumonia, and a pupil of Dr. Todd, Dr. Sanson, spoke rapturously in praise of the present favourite of British physio, alcoholics. With these exceptions there seemed little difference of opinion, and with regard to the use of the heroic remedies of calomel and tartar emetic, they may be said not to be *out of fashion*. Nursing, nourishing and easily digestible food, and wine, *et voilà tout!*

CHOLERA has appeared at Kieff, in Russia.

Society for Relief of Widows and Orphans of Medical Men.

THE half-yearly General Meeting was held, October 27, at the rooms of the Society, Berners street. The chair was taken by the President, Dr. Burrows.

A short statement was read by the Secretary, from which it appeared ten members had been elected since the last general meeting; 5 additional widows and 21 children had made applications for relief.

The actual receipts from 1st January to 30th June had been £1,608, the expenditure £1,379 10s. The grants made to the widows and children amounted to £1,250 10s. for the half year, the expenses £129.

There are at present 56 widows and 43 children receiving assistance in sums varying up to £50 per annum for each widow according to her need, and up to £25 per annum for each of the children.

The President, after acknowledging a vote of thanks to himself and the Court of Directors, expressed his regret at the small attendance of members at the general meeting. Although it was in itself a proof of the confidence placed in the officers, still he much wished the members would show more interest in the affairs of the Society, by appearing in greater numbers at the half-yearly meetings.

Sir James Alderson, M.D.

SOME weeks ago we announced that the President of the Royal College of Physicians of London was to be knighted. We have now the satisfaction of stating that on Thursday last the honour was conferred by Her Majesty, at Windsor Castle. We hope the powers that be will distribute a few more distinctions in the Profession. In every other country these honours are more freely given to distinguished medical men.

Deaths from Chloroform.

A PAINFUL case occurred last week at Oxford. A Commoner of Lincoln College had an operation performed by his usual attendant. Just as it was over the patient's pulse failed, and he was dead in a few seconds. He seems to have had a fatty heart. It is important evidence that he had previously taken chloroform. The surgeon was assisted on this occasion by a pharmaceutical chemist! We are not about to say that he might not have given the chloroform without any assistance, but we do not advise any one taking unnecessary responsibility, and in a place like Oxford there must have been qualified professional brethren, who could have been present.—At Jersey, a man, aged 50, a patient in the general hospital, died from drinking about a spoonful of chloroform. The head nurse had allowed him to smell at the bottle, and he put it to his mouth and swallowed some before it could be snatched away. In an hour he became drowsy, and died in about three hours.

The Birmingham Training Institution for Nurses.

THIS Institution is gradually developing into a most useful charity. Several trained nurses are now employed in the General and Queen's Hospitals, and in the wards of both a goodly number of probationers are receiving instruction. The public, too, are learning the value of good

nurses, and already the demand for nurses exceeds the supply at the Home. Money, too, is gradually coming in, and in all respects save its government the Institution seems most successful. Only a few days since the Committee met to consider the propriety of the Training Institution taking charge of the whole of the nursing at the Children's Hospital. Much is to be said in favour of such a scheme. In children's wards the probationers would earn many insights in the management of children not to be acquired elsewhere, and most important in private nursing. The character of the cases treated would also render such training ground a useful preliminary to the work of the larger hospitals, and gradually prepare the more refined and on this very account, the more valuable nurses for the more trying work of a general hospital ward. The scheme, however, was not adopted. An arrangement was made by which the Lady Superintendent of the Nurses' Home will probably superintend the nursing at the Children's Hospital, in addition to the other duties. This compromise may be wise, but it certainly does not appear so. It will apparently create a second body of trained nurses attached to the Children's Hospital, but independent of the Home—a result which can add no strength to the latter charity. The Training Institution is governed by a mixed committee of ladies and gentlemen, but the multitude and variety of councillors does not seem to have produced great wisdom. From what has reached us we gather that the great majority of the ladies were strongly in favour of taking charge of the nursing at the Children's Hospital, while the gentlemen were divided by conflicting opinions. When such conditions occur in a Committee of the male sex a compact body of half, or even less than half, can carry its own views. In this case the ladies, in spite of their majority, and most probably from a want of that discipline which a habit of transacting business engenders, were defeated utterly. The subjection of women is evidently not yet at an end.

Address to Dr. Mulligan, of Flurry Bridge.

IT is too often our complaint that there is little recognition for long and earnestly honest services of medical men. Here and there, however, such services are appreciated, and, if it be only in words, such recognition is valuable, and we could wish it to be more general.

Dr. Mulligan, of Flurry Bridge, after fourteen years' official connection with the locality, has deserved and obtained such an expression of cordial good-will, and we have pleasure in giving publicity to its terms:—

DEAR SIR,—We, the undersigned, have long desired to testify our gratitude to you by presenting you with an address and suitable accompaniment for the unceasing kindness and attention you have ever shown to us in the discharge of your duty as Medical Officer of our Dispensary District for the long period of fourteen years.

During that time we have ever found that no inconvenience was too great, no difficulty insurmountable. You were always found to be the friend in deed and the friend in need. We therefore earnestly beg you will accept this small Testimonial of the esteem you are held in by every member of this your large district. Our earnest prayer is that you may be long spared to your family, your friends, and to us, where there is such a wide field for your usefulness.

[Here follow the signatures of the subscribers.]

Reply.

MY KIND FRIENDS,—To receive this testimonial of

your good-will towards me, and approbation of the manner in which I have, for fourteen years, discharged the duties of Medical Officer of your Dispensary District, constitute one of the happiest moments of my life, and fills me with feelings of pride and gratification. It should be always an object of pride to obtain the good-will and respect of those among whom you reside, and there is no way more effectual in doing so than making the golden rule—of doing to others as you would wish others to do to you—the guide of your actions and conduct. I have endeavoured to do so, both as your medical attendant and neighbour.

I also feel grateful to you for this tangible and valuable expression of your feelings towards me; it will animate my future exertions, and gratify me by the reflection of possessing your sympathy and respect.

Hoping that the great blessing, "health," may abound in all your homes, I again thank you most sincerely.

THOMAS MULLIGAN.

October 13, 1869.

A Miraculous Doctor.

ANOTHER prodigy of healing has become the rage in Paris, and the *bourgeoisie* are running after him with all the impulsive volatility of Parisians.

This new star is Dr. Girard von Schmitt. Already great people have availed themselves of his powers, said to be unequalled. Dr. Schmitt is supposed to have cured Alexandre Dumas of cancer of the tongue, and a not less serious throat disease. He has healed M. de Barrèze, Consul at Jerusalem, of a scorbutic affection, accompanied with gangrenous ulceration; relieved the Countess of Asck of a rheumatismal affection, from which she has suffered for fifteen years; saved Madame Bruegan from cancer of the eye; protected thousands of other persons, if not from death, at least from fearful pangs. The Editor of *L'Union Médicale* says, that on a visit to his house he saw there, "invited by the new-born celebrity of the young and skilful practitioner, patients of all nationalities."

Have we not Schmitts of our own? Where is Du Barry and the wonderful cure of a fifteen years' cough, No. 69,342?

Cholera Sources in the East.

M. LARREY has presented to the Academy of Sciences, on the part of M. Thologan, principal Medical Officer and Physician to the Shah of Persia a work ordered to be printed both in Persian and French.

The author first alludes to the establishment at Teheran of a Health Council.

The great question of the prophylaxis of epidemic disease, and especially of cholera, is dealt with in M. Thologan's work. He declares that "Persia is not, as it has been unjustly said, a centre for the emission of contagious disease." He discusses the measures adopted by the International Conference at Constantinople, "where," says he, "without precise data as to the sanitary state of Persia, without information as to the habits of cholera there, measures have been arranged which are intended to secure Turkey and Russia by restrictions on Persia.

M. Thologan has no belief in the efficacy of sanitary cordons, or in quarantine on land; and he adds, "I am convinced of the impossibility of realizing in the East arrangements which have not more inconveniences than utility."

He advises the complete interruption of the communication, and especially of pilgrimages from Afghanistan in cases of epidemic cholera there. He does not think it urgent that the sanitary regulations of the Persian Gulf should be altered, and he proposes the complete interdiction in Persia of pilgrimages in case of epidemics there or in Mesopotamia.

DR. GREGSON has been elected Sheriff of Newcastle-on-Tyne.

DR. PATTERSON has received a licence to use his Turkish decoration.

DR. J. D. HOOKER, the botanist, and Director of Kew Gardens, has been gazetted C.B.

DR. PURNELL has been elected, for the third year, Mayor of Wells; and Dr. Rolston, for the second time, Mayor of Devonport. Dr. Ley has been elected Mayor of South Molton; and Dr. Moore, of Hartlepool.

A COMMISSION has been appointed to inquire into the outbreak of cholera at Umritsur, of which we have given a few particulars. We regret to hear that Dr. Bell, of the 36th Regiment, has perished in that epidemic.

THE Syme Testimonial, inaugurated in London, is already a success, more than £700 having been promised. The meeting accepted the plan to establish a "Syme Surgical Fellowship" in the University of Edinburgh, and to place a marble bust of the great surgeon in the Hall of the New Royal Infirmary.

TYPHOID fever has been very prevalent in Sutton-in-Ashfield for the past five weeks, confining its ravages to the most crowded parts of the town, where sanitary arrangements are most defective. The mortality, however, we learn, compared with the number of cases treated, is small and below the average.

Transactions of Societies.

ARMY MEDICO-CHIRURGICAL SOCIETY OF PORTSMOUTH.

NOVEMBER 3.

Deputy Inspector-General Dr. GORDON, C.B., in the Chair.

ASSISTANT-SURGEON DICK, in the absence of the Hon. Secretary, read a statement of the accounts of the Society, and a list of the medical officers who are at present members.

Dr. GORDON then read the following address:—"Since last we met several members and zealous supporters of our Society have left us, their places being taken by others who, joining now for the first time, have, in a measure, had to take for granted the objects for which our association was instituted. In meeting, as we now do, to begin the work of a new session, I would, therefore, briefly mention some of the considerations my brother medical officers had in view when, nearly two years ago, the Army Medico-Chirurgical Society of Portsmouth was brought into existence. They felt the want of ready means of meeting together for the interchange of views on matters of professional importance, which, in a garrison such as this, are of frequent occurrence; they, moreover, ex-

perienced difficulty in obtaining that ready access to current professional literature which is absolutely necessary in order to maintain knowledge on a level with the advances that are being made ; and they further experienced the inconvenience of having no common room in which, during intervals of leisure from duty, they might assemble for the purposes of friendly intercourse. I believe that these several wants have been supplied, and that while our Society affords us the means, at a very small expense, of consulting the periodicals and works of the best authors of the day, it fulfils that other purpose of enabling us all to meet on equal terms, and cultivate that mutual good understanding and interest in the duties we have severally to perform, which conduce so much to our efficiency as medical officers, and thus to the direct advantage of the service. Hitherto we have all worked together harmoniously and well. My cordial desire is that we should continue to do so ; and if, as I hope and trust, our Society shall be the means of attaining this important end, one, at least, of its purposes will have been attained. But I would express a hope that another object will be gained from our more formal gatherings. The public papers—medical, military, and general—have hitherto given ready access to abstracts of the more important papers which have been read at our monthly meetings ; our professional brethren in the sister service and in civil life, some military officers, and several gentlemen unconnected with the public services or the profession have honoured us with their countenance. Thus the nature of the duties performed by army medical officers are made known beyond our own immediate sphere, and every credit given to those of our members who actively exert themselves in preparing and reading papers on such occasions. I believe that were societies such as ours multiplied throughout the army, the interests of the service would thereby gain considerably, and good understanding be enhanced between members of different branches of the service who would thus be brought together. They would realize the fact that the British army, like a huge machine as it is, consists of many separate portions, upon the harmonious and combined action of all of which its efficiency depends. Let me, then, glance briefly at some of the more important duties which we, as members of the army medical department, have to execute. We have to see that suitable *material* in the shape of recruits is supplied, for which purpose a knowledge of the duties required of soldiers in peace and in war is necessary, as well as the power of readily judging from physical aspect the probabilities the young man before us has of improving or degenerating by the new routine to which he is about to be subjected. In the next place we are charged with the duty of preserving the soldiers, when obtained, in the highest possible condition of health, whether they are quartered at home or in the tropics, in times of epidemics, in war, or in the no less trying conditions of temporarily holding in military occupation unhealthy stations. It has for some time back been the custom to employ the phrase “sanitary condition” to other states than are here indicated. Thus it has come to be synonymous with conservancy or scavenging. In either of these its true meaning is lost sight of, and, what is of more consequence, a very partial and incorrect significance is conferred upon it. In order that we may offer trustworthy views on hygiene properly so called, we must be acquainted with the science of geology, and the nature and property of soils ; we must have a knowledge of meteorology in reference to its bearing upon the human system ; thus means of preserving health in a damp climate with great extremes of temperature and negative indications by the electrometer, would be exceedingly unsuited to a dry climate with small variations and the prevalence of positive electricity. In order that we may offer trustworthy opinions in regard to sites for barracks, more especially abroad, it is essential that we should be acquainted with the conditions which affect the relative temperature as indicated by transmitted heat and by solar radiation. To enable us to offer a scientific opinion in regard to the food most likely to be obtained in a particular country, or the vegetables that may with greatest promise of success be cultivated there, we must know something of scientific and descriptive botany and of the natural distribution of plants ; and so on with various other examples of our duties in which special scientific knowledge is an absolute necessity. As a matter of course we have to treat the troops when sick, and under all conditions of service. But we have to do more than this. While acting as physicians, surgeons, and apothecaries one day, we have the next to assume the character of accoucheur and sick nurse at the same time. It is difficult to indicate clearly to those of our countrymen who live at home

at ease how it is that we have to thus act in so many different capacities ; but to those who have seen our regiments abroad, in small and isolated stations, or on the line of march in India, there will be no difficulty in following me in my remarks. It next becomes our duty to weed the regiments under our respective charges of those men whose ailments or accidents are of such a nature as to be apparently not amenable to treatment ; and here our duties are not only special in their nature, but altogether different from the medical man's in civil life. He treats his patients each with reference only to himself. We treat the soldier not so much in reference to himself as with regard to the efficiency of the general body of which he is an atom ; and inasmuch as the choice of an attendant does not rest with him, so, instead of his discharging his medical man when no longer needed, the medical officer discharges him, perhaps very much against his will. Turn we now to active military service, and let us enumerate a few of the duties of our department. It is to the medical officers that the general in command must look for an approximate estimate of the ordinary casualties by sickness, death, and invaliding, which, with reference to climate and general conditions, he may lay to his account, and desire reinforcements from the mother country to fill the vacancies thus to be created ; to them he has to refer for approximately near views of the quantity and nature of conveyance, accommodation, servants, medicines, and appliances for hospital purposes which should attend an army ; and to them he must refer in regard to the mode of travelling best suited to non-effectives when being finally disposed of as invalids. To the exertions and the knowledge of army medical officers, the soldier is indebted for almost every improvement in his condition that has from time to time been made. I have elsewhere, in writing, and in remarks delivered before this Society, dwelt upon some of the more important of the advances in hygiene, for which the sole credit is due to the officers of our department. For example, it was at the urgent representation of an army medical officer that suitable barracks for our soldiers were erected ; that a definite proportion of cubic and superficial space per man was allotted ; that in malarious districts upper storied barracks were provided ; that suitable rations in quality and variety were issued ; that clothing has been issued with due regard to climate and nature of duties ; that canteens were established with a view to check in some measure the terrible extent to which drunkenness prevailed ; that suitable buildings as hospitals were founded ; that hospital diets were instituted with due consideration for the requirements of the sick ; that a restriction, as far as practicable, was placed upon the amount of night duty, drills and exercises to which the troops were subjected ; as well as many other improvements which I could enumerate. Nor must I omit to mention that many of the moral improvements which have of late years taken place in the condition of the soldier were first advocated by the medical department, as, for example, recreation rooms, the gymnasium, temperance associations, savings banks, schools, and others, while among the first advocates of the abolition of corporeal punishments we find the name of an army surgeon. Considering the greater efficiency as soldiers of married as compared with unmarried men, it is not to be wondered at that army medical officers have ever advocated the extension of liberty to marry among them, or that they have been among the foremost advocates of increased consideration to their wives and children. The army medical officer must be acquainted not only with the phenomena of diseases which affect masses, but also with the laws which seem to influence epidemics. Thus he must be able to recognise and treat according to the principles of his art individual cases of these, to suggest suitable and *practicable* measures with a view to limit as far as may be possible the ravages they are capable of committing. In many instances, as you are aware, sporadic diseases of various forms of this class of maladies occur. It is for the medical officer to discourage alarm in such a case, but with his knowledge of the fact that diseases which thus occur are capable of propagation from each case as from so many centres of infection, it becomes his duty to suggest such precautions as are likely to afford the greatest protection to the body of troops under his care. In these and various other respects it must be apparent to all that the duties which we perform are important as well as special in their nature. They demand not only long training upon our parts, but a certain aptitude, just as much as other specialities require on the part of those who would prosecute them with success. Nor is it only to the so-called executive officers of the medical department that these remarks apply. If the duties of the adminis-

trative branches are still less of what belong to the practitioners of medicine in civil life, they are not the less important on that account; no less special. Let me briefly remind you of a few. The principal medical officer of a district in England—say that of which Portsmouth is the head quarters—visits the hospitals of all the corps in garrison once a month, and performs twice a year a regular formal inspection of all throughout the district, preparing a report of the manner in which they are severally conducted. He sees, in company with other regimental officers, important cases, and all in which a capital operation is considered to be required, his sanction being, by regulation, required before one of a serious nature can be performed, except, of course, in cases of emergency. He has to summarize as well as examine statistical reports on sickness and hygiene, prepared by regimental surgeons; has to make preliminary arrangements that regiments arriving in the district have suitable requirements for their sick; he has to see that superfluous establishments of corps about to move are properly disposed of; has to check the expenditure of what are called 'extras' issued; to see that sufficient reason is shown by medical officers for any attendants beyond the authorized number whom they may employ in their wards. Many other duties have to be performed by him, which I rather enumerate as they occur to me than attempt to classify. He has to offer his professional opinion with regard to proposed appropriation of buildings as barracks or hospitals for the troops, in regard to repairs in connection with them, and in regard to their hygienic arrangements, including heating, light, ventilation, water supply, and conservancy arrangements. In the event of infectious or epidemic disease threatening, it becomes his duty to suggest to the general officer commanding such measures as are best calculated to avert the spread of the malady, as well as to propose any special measures that may have particular reference to individual sufferers. He has to make arrangements for the proper examination of non-commissioned officers who desire to qualify as compounders of medicines, and of men who desire promotion as non-commissioned officers in the Army Hospital Corps. He has to sit as President of Boards or himself adjudicate in the cases of recruits objected to for medical reasons by surgeons of regiments; on the cases of officers arriving from abroad on sick leave, falling sick, or making application for compensation on account of wounds. He has to make suitable arrangements in regard to the distribution of medical officers in the district with reference to the requirements of the troops; has to keep the roster of those in garrison, so that each shall serve in rotation, and no more, in connection with boards of various kinds, and as visitors of the garrison cells. He has to check the returns of expenditure of medicines and of extras in regimental hospitals, and to satisfy himself that, with respect to the latter, existing regulations have been complied with. He has to verify and sign the bills submitted by medical officers for travelling allowances, and now, under the recently introduced system, to approve the pay bills of those who do not belong to regiments. He has to nominate medical officers to accompany detachments proceeding to small stations, and to arrange, where occasion arises, for opening a hospital for the treatment of their sick. He has on occasions of garrison field days and public reviews to make suitable arrangements for casualties that may occur. He has not only to check requisitions for medicines and instruments received from regiments, but also to superintend those sent in for the general supply of these for the district. He has to examine all instruments requiring to be repaired previous to submitting an estimate for the purpose. He has to inspect regiments about to proceed on foreign service from the district, selecting men who are likely to be efficient in the country for which they are destined. He has to see that troop-ships are properly provided with all medical requirements before leaving the port, and that the medical officers proceeding in charge are provided with all necessary requirements for performing their duties. There are various other offices which he has to perform, but the list I have given is, I think, sufficient to indicate the more important, of which it is only necessary to observe that, as must be obvious to any person, much of the well-being of the officer, the soldier, and his family depends upon the efficiency with which they are executed. It is with no desire to magnify the importance of the duties performed by us that I give this brief summary. As I have already observed, no one branch of the army is really more important than another, but there is this very material difference between the armies of civilized nations and those of uncivilized, that whereas the sacredness and the value of human life being recognized by the

former, and every practicable means adopted to economise it, no such sentiment exists in the case of the latter, and consequently no organization maintained to save the fallen in battle or those who are stricken by pestilence. Time does not permit me to dwell further, or enlarge upon my theme. I trust, however, that the few brief remarks I have had the honour to offer may serve to recall to your recollection some of the many important and responsible duties we have to perform, and also the fact that, in proportion to the efficiency with which they are discharged, so will the interests of the military branches of the public service be advanced."

A paper was read in which Surgeon PORTER, 97th Regiment, gave a description of a sling for bed-ridden patients, invented by him. Sketches of the contrivance were handed round, and these illustrated the manner in which it may be used in ordinary hospital practice, and in field and camp hospitals, for both of which it is especially well adapted. The sling may be made so as to be portable, and at a very trifling expense, and should, in the opinion of Dr. Porter, form a part of the equipment of all regiments on service. It consists of a piece of strong canvas, 24 inches by 18, having, if necessary, an opening in the middle; at either end it is stretched upon pieces of wood of the size and shape of ordinary rollers, and secured by means of "stays" spliced together to cords which pass through small blocks, thus by a fulcrum, whether post or hook, a patient can be raised from his couch; and such dressings applied as may be required. We shall publish this paper in full shortly.

The CHAIRMAN drew the attention of the members to a beautiful collection of shells presented to the Society by Captain N. B. Bedingfeld, R.N., commanding H.M.S. *Gladiator*, and arranged and named by Mr. Tyler, of Southsea. The collection, which was an extensive one, included specimens, many in duplicate, of the families known as *Cones*, *Cowries*, and *Olivcs*. He exhibited a number of geological specimens presented by Assistant-Surgeon T. Maunsell, of the Royal Artillery. They had all been collected from among the eocene and wealden strata in the Isle of Wight, more especially from the former at and in the vicinity of Alum Bay, and the latter at Brook Point. Among them were numerous shells, all in a good state of preservation; a fragment of the *Pycnodus*, the teeth of which were arranged in the palate in a manner somewhat similar to stones in a pavement, the fish so named being an antetype of the sea-bream of the present day; a scale of the *Lipidotus*, a so-called ganoid fish, whose modern representative is the "bony-pike" of some of the American lakes. There were also some vegetable impressions in the pipeclay of Alum Bay. Of remains of Saurians there were teeth of crocodiles of the Wealden period, showing the mode of dentition in those reptiles, which seem to have been allied to the alligators and caymans of our own day; various fragments of the *Iguanodon* and *Hæliosaurus*, some bones of fossil turtles, and vegetable remains of the forest contemporaneous with the creatures to which they had belonged.

Surgeon-Major LEITCH, 46th Regiment, proposed, and Assistant-Surgeon BALL, 33rd Regiment, seconded, a vote of thanks, which was unanimously carried, to Captain Bedingfeld, R.N., commanding H.M.S. *Gladiator*, for the beautiful and extensive collection of shells he has presented to the Society; and to Mr. Tyler for having been so good as to arrange and name the individual specimens. A vote of thanks to Assistant-Surgeon Maunsell, R.A., proposed by Surgeon-Major Sinclair, 33rd Regiment, and seconded by Surgeon Shipton, 2nd Regiment, was unanimously passed for the collection of geological specimens presented by him to the Society. A vote of thanks to the Chairman for the address read by him, proposed by Surgeon-Major Leitch, and seconded by Dr. Elliott, R.N., was unanimously passed.

Correspondence.

LARGE FAMILIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is not easy to make out what "Prudentia" wants. Is it to be recognized as the first enunciator of the "connection between large families and the prevalence of vice, pauperism, disease, and premature death?" I am almost tempted to suspect that he is disappointed at not being acknowledged the discoverer of this connection. I cannot otherwise explain to myself why he should take exception to my statement that

"the mere question of the advantages which arise from the number of children being somewhat in keeping with the financial means of the family and the physical ability of the wife satisfactorily to bear and rear offspring is not one that can occasion much discussion."

But "Prudentia" should not have allowed this little disappointment to betray him into garbling and misquoting the sayings of others. In his communication of the 10th inst. he writes:—"J. D. M. dismissed my propositions with the remark, 'the mere question involved is not one that can occasion much discussion.'" The words (correctly given above) here referred to were used by me in *introducing* my observations, and had no direct reference to any specific propositions of "Prudentia." Consequently I did not *dismiss* "the propositions" with that remark.

He has, it seems, some practical plan of limiting the number of births in a family, which has been alluded to neither by me nor by your correspondent A. G. L., whose communication followed mine, but "does not think the time has arrived to explain" what it is. He desires to have previously discussed his views and propositions relative to the evils attendant on large families. In my humble opinion, however, if the time has not now come for "Prudentia" to explain his plan, it assuredly never will. To hold out for further preliminaries might have the effect of bringing to mind the circumstances under which the mountain was fabled to have brought forth a certain very small family.

Yours obediently,

J. D. M.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The appearance in one week of two articles upon the question of population in two such important journals as your own and the one above adverted to, bespeaks the deep and sincere interest which all highly cultivated medical men take in questions relating to human happiness and social tranquillity. I may take the liberty of saying, in passing, that ever since the *British Medical Journal* came under the direction of its present illustrious editor, it has cast aside all flippancy, and is becoming what it ought always to be—the journal of a serious and deeply responsible profession. Many of your readers, Sir, may have shared the joy which I felt on reading a leading article in that journal of Saturday last, November 6, entitled, "Early Marriages." The article was, with a few slight exceptions, one which I should have myself been but too proud to have written. Indeed, the sentiments are so like those I have had the honour of expressing on several occasions in your highly esteemed and most tolerant of all medical journals, that some of my friends who did not, I suppose, see how much better the style of the article was than anything I can aspire to, have been so good as to ask me whether I was the author of it. The writer of the article frankly confesses himself as entirely convinced that the discovery made by the illustrious Anglican divine, Malthus, at the beginning of this century, that our race has a tendency to increase, in old countries such as this, far more rapidly than food can be obtained for it, was one of the most important truths ever discovered by man. I entirely concur with this sentiment, for I believe that the discovery of Malthus was by far the most important one ever made in science, in its bearing on human health and social happiness. Before the day of that discovery, the race we belonged to had been living without a magnet to direct its course towards the great end of all our arts, namely, happiness.—Wars, pestilences, famines, prostitution, all sorts of injustices, seemed destined to exist for ever; because no philosopher before that time had seen clearly the fact that all the virtues in the calendar ended in nothing but social shallows, poverty, and early death, unless there was a strict limitation of the number of births in a country. It was shown in the great "Essay on Population" which the article in the *British Medical Journal* so highly praises, that our race tends, when abundantly supplied with food and other necessities of life, to double in from perhaps fifteen to twenty or twenty-five years. In the United States of America, for instance, Mr. Malthus showed in his essay in the "Encyclopædia Britannica" on population, that from 1790 to 1810, the inhabitants of that country very nearly doubled in number in twenty years, by the mere powers of procreation, inherent in the race, and making full allowance for immigration into the States during that period. Mr. James Mill has well shown too, how easily this law is deducible from the facts known with regard to the menstrual life of woman.

The law of nature that mankind tends to double in, say, less than thirty years, is now so incontestably proved, that it is considered by readers of Malthus, Say, Ricardo, Senior, James and J. S. Mill, &c., &c., quite axiomatic. Once admitted, however, it becomes the chief law of hygienic science. It is the key, without which subjects such as poverty, overcrowding, infantile mortality, infanticide, or prostitution, cannot be opened up. A writer or speaker, then, who wishes to treat of such momentous questions ought to study these works carefully before presuming to speak upon them. And this is what the writer in the *British Medical Journal* has done.

The occurrence of poverty is accounted for on the Malthusian theory of population, by saying that the rapid increase of men in old countries tends always, unless restrained, to grind the poorer classes to dust. This law also explains the occurrence of so much early death among the children of the poor, as compared with those of the rich. It explains the miserable phenomena of infanticide and prostitution, both of which are, alas! so common, even in London. And here the theory of Malthus promises a very different future for the race in these respects, than it has hitherto had to undergo. Your correspondent "Prudentia" has well pointed out in the *Elgin Courier*, and in your columns, that if people in this country would only give up the habit of having large families, it would be possible to look forward to an immense diminution in the rate of infantile mortality, in the amount of prostitution, and I may add, Sir, in the amount of consumption, fevers, and other pestilences, with which we are so continually and periodically haunted. This, the production of large families, he well argues, is the cause of almost all the preventible diseases; because large families cause overcrowding in narrow rooms, bad food for children, and want of education, and poverty. I cannot sufficiently praise the benevolent attempts of those two gentlemen towards directing the attention of what is by far the most important of all the professions, the medical, to this subject. It is true that the article in the *British Medical Journal* recommends in company with Mr. Simon, in his recent pamphlet, early marriages, as a means of preventing venereal diseases, without quite showing his readers that he entertains the views of "Prudentia," and intends his young married couples not to breed too rapidly. But his other views would lead me to suppose that he means the same thing.* We may, therefore, conclude, that those gentlemen both agree with my formerly expressed opinion (see MEDICAL PRESS AND CIRCULAR), that early marriages, with very small families (and I may add on my own account, freedom of divorce), are the only solutions of the problem how to get rid of poverty, syphilis, and to lessen the frequency of phthisis. Now, with regard to the question whether it is possible to have small families, that point, of course, has been long set at rest by the knowledge of the fact that the French nation, as shown by statistics, and as mentioned in many French works on the subject, such as J. Garnier, Mayer, Maurice Block, &c., habitually, in a great many instances, voluntarily limit the number of their children to two. There is, then, no *impossibility* in following out the recommendations of J. S. Mill, Garnier, Sismondi, and others. Mr. Mill's expression that "little improvement can be expected in morality, until the production of a large family is looked upon in the same way as drunkenness or any other physical excess," shows how strongly he feels as to the necessity of persons only having very few children.

With regard to the means taken by the French, perhaps "Prudentia" is not far wrong in his remark of last MEDICAL PRESS AND CIRCULAR, that there are so many intolerant people, even in the noble profession of medicine, yet in this country, that it is hardly time to discuss the details of the question yet. For example, when the President of the College of Surgeons, Mr. Solly, can utter such an opinion as he has once or twice been reported to have done, that venereal diseases are sent by Deity in order to keep mankind in order, it is clear that even the medical profession is not free from the follies of *à priori* or transcendental theological absurdities. But the views of "Prudentia" on this topic admit of question. Is it necessary, I ask my *confrères* seriously, much longer to put up with the pretensions of theologians, to instruct us medical men upon matters which, of course, we know very much better than they can? Is it necessary much longer to maintain a reticence upon the questions which are by far the most important in the science of hygiene, because some reverend fathers of the Roman Catholic Church, or other

* This is an error. In the *Journal* of Nov. 13 the writer advocates early marriage and emigration.—C. R. D.

equally enlightened persons, choose to denominate conjugal prudence as the most damnable of mortal sins? I put, Sir, this question to "Prudentia," and to others who think like him. For my own part, I applaud plain speaking in medical journals: we have no secrets. The human body is known to us in all its details, and I want to know for my part, the best means to avoid poverty and overpopulation, without, as Lord Amberley said, doing damage, if possible, to human happiness and health. As "Prudentia" objects to the French, perhaps he would kindly give us the benefit of knowing how he proposes married people to limit the number of their children without any sacrifice.

I remain, Sir, yours faithfully,
 CHARLES DRYSDALE, M.D., M.R.C.P.L., F.R.C.S.E.
 Southampton row, W.C., Nov. 11th, 1869.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.
 SIR,—The numerous physiologists who have lately written upon the imprudence of having large families have omitted to mention the fact stated by some French observers, and admitted by Marion Sims to be for the most part the rule, that conception cannot take place during the ten days preceding the menstrual period, intercourse then being unfruitful.

MEDICUS.

IN MEMORIAM.

RICHARD GRIFFIN.

FULL of years and full of honour, the father of Poor-law Medical Reform sinks into the grave, followed by the affectionate remembrances and the tearful regrets of all his professional brethren, and of all who knew anything of his high worth and noble aims. The heart of many a medical reformer will sink within him as he hears that this master in Israel has fallen. Let his example stir them still to emulate his deeds, and their regrets shall be hallowed.

There is none to take his place. Only his work accomplished remains to us. He had fought a good fight, and now he rests, the benisons of all following him home.

Medical News.

NAMES of gentlemen who have obtained the diploma of Licentiate of the Royal College of Surgeons of Edinburgh, between August 1st, and November 11th:—

SCOTLAND.

GLASGOW & ABERDEEN UNIVERSITIES' ELECTION.

THE LIBERAL COMMITTEE strongly urge ELECTORS who have not yet Voted, to lose no time in sending in their Voting Paper for Mr. Smith. They will be in time if sent to Glasgow or Aberdeen by the afternoon post of the 18th.
 Voters resident in Middlesex, Westminster, Surrey, or Kent, calling at THE LONDON COMMITTEE ROOMS, 3 STONE BUILDINGS, LINCOLN'S INN, Will have their Votes attested at once, without trouble.

SURGEONS' AND CHEMISTS' PRINTING, ENGRAVING, &c. Best quality. Moderate charges. Labels of all kinds. Hospitals and Dispensaries supplied by contract or otherwise. Catalogues and Specimens gratis. Account Notes, any pattern. DUBLIN STEAM PRINTING COMPANY, 94, 95, and 96 Middle Abbey street, Dublin. LONDON OFFICES:—34 Southampton street, Strand, W.C.

J. J. GRAHAM AND CO.
 BEG TO ACKNOWLEDGE with most grateful feelings the liberal and increasing patronage bestowed upon them by the Medical Profession, and to assure them that it is their constant aim to render themselves deserving of a continuance of their support.
 J. J. GRAHAM AND CO. confine themselves strictly within the limits of the Pharmaceutical Profession, and under no circumstances do they take upon themselves Medical or Surgical duties, other than those performed by the Apothecary under Medical directions,—namely, Cupping, Leeching, Blistering, &c.
 As the value of a Prescription is completely dependent upon the therapeutic efficacy of the medicines ordered, J. J. G. and Co. are most particular in keeping up a stock of the purest Chemicals and freshest Pharmacopoeia preparations. Every article used in the making up of Prescriptions procured from the first Houses regardless of cost, and such as are at all liable to adulteration tested before used; the Profession may therefore rest satisfied that the medicines prescribed will be of the best quality, and carefully compounded under the immediate superintendence of the Principal (J. J. Graham), who resides on the Premises and devotes his whole time and attention to the management, supervising the operations of the assistants, and who is accessible at all hours.

EXPERIENCES OF A REGIMENTAL SURGEON IN INDIA.

By C. A. GORDON, M.D., C.B.,
Deputy Inspector-General of Hospitals.

(Continued from page 360.)

MENTAL AFFECTIONS.

DURING the first year the 10th Regiment was in India only one case of mental disorder occurred, and it of melancholia. In the second year there were four, namely, three of monomania, supposed to be due to intemperance, and one of melancholia, attributed to the patient having at one time received a blow on the head. In the third there were three cases, namely, one of monomania, the result of intemperance; one of melancholia, from injury to the head; and one in whom the affection was assumed, the malingerer being subsequently sent back to duty. Only one case occurred in the fourth and fifth year, the nature of which is not recorded; but the fact may be noted that, in the former of these, the regiment was engaged in an arduous campaign against the Sikhs, and went through several well-contested battles. In the sixth year one case occurred, namely, of amnesia, the cause of which was not apparent; but the attack was temporary, the patient having recovered within the twelve months. The following year, however—that is, the seventh—five cases, all of amnesia, occurred, the causes of attack being in all obscure. In the eighth, two cases, both of mania, occurred. The cause was in one obscure, and the patient had to be invalidated; in the other, the attack was attributable to intemperance, and the patient recovered. Four cases, all of amnesia, occurred in the ninth year. In one drink was the cause, and the patient had to be invalidated; in the three remaining cases the cause of the affection was obscure. Two of the patients recovered, and one was sent to England

as an invalid. In the tenth year two cases occurred, namely, one of amnesia, arising from intemperance and repeated attacks of delirium tremens, the patient being subsequently sent home as incurable; the other, a case of mania, seems in reality to have occurred in a person labouring under ordinary phrenitis. In the eleventh year three cases came under notice. In one the symptoms were suspicious, so much so that the patient was only taken under observation; after a time, however, he manifested symptoms of mania, and died of phrenitis. The second case was feigned, its subject ultimately returning to his duty. The third case was, to say the least, suspicious, and happened in a soldier who, there was every reason to believe, had determined to incapacitate himself from military service, although with the alternative of being transported for life. With this view he struck a non-commissioned officer, and, while being medically examined as to his fitness to undergo punishment, then struck me. I myself raised the question of his sanity, more with a view to shield him against the probable consequences of his offence, seeing that assaults upon officers were at the time becoming so frequent that sentence of death had at last to be carried into execution to put a stop to them. This soldier was acquitted of his crime on the plea of insanity, and sent to the Government Lunatic Asylum. After remaining there a year he was discharged to join his regiment, but while *en route* died of cholera. In the twelfth year three men, labouring under anomalous symptoms, were taken under observation; two of them ultimately returned to their duty, but the third having been retained many months under observation, under the belief that he was simulating insanity, became affected with low fever, under which he rapidly succumbed. In the thirteenth and last year to which my records extend, five cases of mental affection came under observation. In two of them the form of disease was unquestionably amnesia, but in three the symptoms were of such a nature as to cause some suspicion regarding their real nature.

If now we analyse the abstract just given, we find that in the period mentioned there occurred in the 10th Foot fifteen cases of amnesia, of which five terminated in recovery; the subjects in nine instances had to be invalidated.

There was one case of mania, the patient dying of phrenitis. Five cases of monomania were recorded, the patients in all being invalidated. There were two of melancholia, also invalidated. There were eight in which the symptoms were more or less suspicious; of these, one patient died of phrenitis, one of fever, two returned to duty, one was sent to a lunatic asylum on conviction of a military crime, and three remained under observation.

It would appear by the regimental returns that the cases of melancholic form of mental disorder were of most frequent occurrence during the earlier period of the Indian service of their subjects. If such be actually the case, it is quite in accordance with what might be expected; but in all probability it needs further confirmation, as does also the equally popular impression that cases of suicide are in proportion more frequent among Scotch soldiers than in either the English or Irish. I do not now remember any instance in which a soldier of the 10th Regiment attempted suicide during the time to which my notes refer. It would seem that the causes which lead some to shorten their own lives had with them the effect of producing personal recklessness, ending in crimes of violence against others, and in outbreaks of dissipation; and this leads me to remark that there are at times episodes in the history of men who enlist as soldiers sufficient in themselves to account for many acts of desperation of which they are guilty before the final act is perpetrated which terminates the period of their personal liberty, or induces the illness which removes them by death or invaliding from the army. I had occasion to see a striking illustration of the truth of this remark while stationed at Wuzzeerabad, in the Punjab, in 1851. Shortly after I had been struck by a soldier, as already mentioned, the Surgeon of the 3rd Light Dragoons, then occupying the same station, was, while visiting the sick, severely assaulted by a soldier of the corps, then a patient in the hospital. Dr. Henderson, desirous, if possible, to save the man from the legal consequences of his offence, suggested that a Board of Medical Officers should meet to inquire into the state of the man's mind. I was President of the Board so assembled, and perhaps on that account was selected by the unfortunate soldier to listen to the sad tale he had to relate. His name was Brown, at least that was the name by which he was known in the 3rd Dragoons. According to his own account, he and a bricklayer's apprentice of the name of (assumed or real) of Eaton, one Sunday night in 1845, while walking along Wandsworth Common, met a drunken sailor. Both of them were at the time "hard up." They had been drinking, and the sight of the sailor, who seemed as if he had come off a long voyage, tempted them to think of robbery and murder. The double crime was speedily carried into execution, and Brown related to me in all their minuteness the means by which they were perpetrated, adding that the proceeds amounted to £40 in money, together with a gold watch and chain. He further informed me that the money and watch were retained, but the chain disposed of in a shop in one of the streets near Drury lane Theatre. In order to dispose of the body a spade was robbed from a house at some distance, a grave dug, and during the darkness of night the evidence of the crime committed to the earth. But one of the murderers, haunted by his crimes, fled first from one place, then from another; and the war in the Punjab then being in progress, enlisted, as he said, in the hope of being killed in battle. By the time he joined his regiment the first Sikh campaign had been brought to an end. For some time he was therefore obliged to undergo the monotonous routine of regimental duty in an Indian cantonment, brooding in secrecy over the one terrible crime he dared not confess. At last the second Sikh war broke out, and when the 3rd Dragoons came in contact with the enemy he rushed desperately on with no other object than meeting death. But he was foiled, and after a couple more years of dull monotony and brooding over his own secret, he determined to strike an officer, in order, as he hoped, to be tried and shot for the offence, as a soldier of the 14th Light Dragoons had shortly before been at

Meerut, for a similar crime. All these particulars were carefully reported by me in the proceedings of the Board at the time. The 3rd, being ordered home, however, left the station, this man accompanying the corps, and I heard nothing more of the man till 1868, when, having to visit the regiment officially at Chichester, prior to its embarkation for another term of Indian service, I inquired after Brown of the one only officer who then remained of those who had left Wuzzeerabad with it. He informed me that the account given by Brown had been verified on their return to England, but that the man himself had become a confirmed lunatic, and had been sent to an asylum. I am induced to give the narrative as illustrating one phase of life in those who join the ranks of the army.

It would be foreign to the objects of these papers to discuss the probable occurrence of what is called *moral insanity* among the different members of a regiment in India. That such a form of mental affection does exist, however, is undeniable, although the line of demarkation between it and ill-regulated passion or vice is so imperfectly defined that it is difficult, nay, often impossible to say at what precise point the one ceases and the other begins. There is, however, much reason to believe that were the views held by authorities in the laws in regard to this important question more in accordance than they are with the truths exhibited by medical investigation, many of the breaches of military discipline committed by soldiers, instead of being, as they so frequently are, visited by heavy sentences, would be looked upon as manifestations of moral infirmity, as much as an ordinary injury or disease is of the physical system, and would be treated accordingly. There is much reason to believe that the mental faculties of both officers and men serving in India, are in a higher state of *exaltation* than of those who reside in more temperate climates. Hence, perhaps, the tendency so general in that country of magnifying the importance of derelictions of duty, and of the more venial offences so often observable there; and hence it may be assumed many of the scandals and acts of tyranny which far too often are recorded in the local papers, or form subjects for the different law-courts there and at home. This branch of my subject is a fertile one, but it may be advisable merely to observe that nowhere more than in India, if indeed anywhere so much as in that country, does the remark hold good, that the subjects of passion, rage, and various forms of mind, are quite as often suitable objects of medical treatment, rather than for the military ordeals, which literally serve to aggravate rather than relieve the *disease* under which they labour. The older I become, the more leniently I feel inclined to look upon many *crimes* committed by men of long Indian service, and of those who have suffered from bodily ill-health there.

The affection known as *nostalgia*, or *home sickness*, which in former years was of frequent occurrence in the army, seems in more recent times to have ceased among soldiers. Probably the altered conditions of service now as in former times have been the cause of this difference, and, if such be the case, the circumstance speaks more than almost any other in favour of the many improvements that have, during the last thirty years, taken place in the condition of the soldier. I may observe that these remarks are meant only to apply to what may be called idiopathic cases of *nostalgia*, or those in which, without the presence of any physical disease, the person becomes seized with a longing to return to his former home and friends, so intense as to amount to a form of monomania. Such a condition is by no means rare during the course of severe or tedious bodily illness, and has an important bearing upon the best manner of disposing of such men with a view to their convalescence and recovery. There are few, if, indeed, any, medical officers in India, who have not been appealed to by soldiers against the proposal to send them to a hill "sanatorium;" these were often declaring that if they could not be sent home to their own country they would prefer remaining among their own regimental acquaintances to being sent anywhere else, and the surgeon of experience never failed to have due regard to the wishes of the man,

knowing as he did that his acquiescence or refusal would exercise the effect of, it may be, restoring in a great measure the hope and strength of the patient, or of consigning him to a weary and desponding period of illness, too often to be ended only by death. This question has an important bearing upon that of having sanatoria for our Indian troops at the Cape, Australia, and elsewhere, in preference to sending them home. I would not now discuss it farther than to observe that I myself have heard sick soldiers declare that if they could not be sent home they would prefer being left to die as and where they were, that one foreign country was the same to them as another, and all they cared for was to get home, meaning thereby to the United Kingdom. While upon this subject I may also observe, that so far as my experience enables me to state, soldiers are, as a body, indifferent to the physical fact of dying. In my regimental career I have only in one instance been asked by a sick soldier as to my opinion of his illness, although I have necessarily come in contact with men of almost all positions of life, education, and characters.

Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

NOVEMBER 15.

PETER MARSHALL, Esq., President, in the chair.

Mr. TEEVAN exhibited to the Fellows

A CALCULUS, WEIGHING 2½ OUNCES,

composed of lithic acid, and the phosphates covered with spiculae, which he had extracted from the bladder of a patient who had walked from Birkenhead to London, 200 miles in 12 consecutive days, the last day having walked 33 miles in the greatest agony. Mr. Teevan having first examined with the lithotrite, and finding the stone large and the bladder irritable, performed lithotomy, cutting low, and having after the first incision to make four separate cuts to liberate the stone. In answer to Mr. Hanworth as to the limit in regard to size of stone in relation to the operation of lithotripsy, Mr. Teevan stated he was guided more by the state of the bladder and constitution of the patient, performing lithotomy in preference to lithotripsy, in irritable subjects. In one case of lithotripsy under his care the *détritus* amounted to 3 oz. in 16 sittings.

Dr. DICK exhibited a

KNIFE SUITABLE FOR ALL OPERATIONS WHERE TWO KNIVES ARE REQUIRED,

the cutting blade being covered at will by a sliding sheath secured by a spring in the handle.

Dr. HAWKSLEY then read a paper

ON THE "STETHOSPHYGMOGRAPH" AS AN AID TO THE PHYSIOLOGICAL AND PATHOLOGICAL INVESTIGATION OF THE FUNCTIONS OF RESPIRATION AND CIRCULATION,

in which he purposely forbore to introduce any deductions or generalisations founded on the use of the instrument; he pointed out the use of taking a large and careful series of observations before the work of tabulation and comparison of facts could be usefully carried out. On this occasion he exhibited the practical application of the instrument on a case of phthisis pulmonalis, and one of well-marked mitral regurgitation. In every case three simultaneous and synchronous tracings of moving organs are taken, as, for example, the two lungs and the radial pulse, or the heart, the radial pulse, the carotid, and the femoral. It was clearly demonstrated that the tracings would show any disparity in the action of the two lungs, also the relation of inspirations and expirations; and associated with the pulse tracing it affords the opportunity of observing not only the peculiarity or modifications of the circulation, as in the case of Marcy's sphygmograph, but in addition their relation to the respiratory process. It is equally certain that by the aid of this instrument any question as to relative time in the transmission of the blood wave through the arteries may be solved, as, for example, the time occupied in transmission to the radial, the carotid, or the femoral artery;

and this may be found to have important connection with the diagnosis of aneurism and tumours, as well as with diseased state of the arteries and with chronic disease of organs. After these demonstrations the author gave a *resumé* of the foundation facts on which the science of stethography is built, illustrated by drawings, diagrams, and an experiment which was very successful in demonstrating the aid that elasticity in tubes affords to the passage of fluids and the comparative impediment of rigidity.

At the conclusion of the paper the President thanked the author in the name of the Society for his elaborate and scientific paper.

Dr. TEMPLE observed that as the paper was not of a controversial character it was not likely to produce discussion. It might be a matter of question whether the result obtained by the sphygmograph might not be attained by other and simpler modes of diagnosis, but in a philosophical point of view it was impossible to withhold admiration from the ingenuity which had devised the instrument and the great mechanical skill which had brought it to perfection. In a physiological, pathological, and therapeutical light, Marcy's invention, as modified by Dr. Hawksley, would no doubt, in time, produce most important benefits to medical science and practice.

Literature.

ON THE USE AND VALUE OF OXYGEN, &c.*

THE application of oxygen to the treatment of disease has long been a favourite idea. The source of this popularity is, no doubt, to be found in the obvious train of reasoning which suggests its use. Ever and anon the flickering spark of some imperfect therapeutical generalization comes in contact with the oxygen hypothesis, and straightway flares up again into a short-lived brilliancy. Happily, these Will-o'-the-wisps are daily becoming more rare and less misleading, for a wholesome spirit of scientific doubt is growing up in the medical mind, and rapidly extinguishing that credulity which has added to our *materia medica* so many useless remedies. We are almost inclined to think that more than half of the knowledge we possess of remedies is useless and false knowledge, and that we should be in a better position without it. As far as oxygen is concerned, we should certainly not be worse off if the book before us had never been written. We have carefully perused its pages, and have failed to discover any precise notions of the *modus operandi* of oxygen, or the diseases for which it is a valuable remedy. We are not surprised at this, for the therapeutical action of any drug is one of the most complex problems the human mind can undertake to solve. To say nothing of the infinite number of disturbing causes which may mar our observations, we must bear in mind that therapeutics can only be scientifically approached through physiology and pathology. We must successively fathom the laws of normal and abnormal function before we can analyse the phenomena following the administration of a drug in health and disease. When physiology and pathology are perfected, and not till then, can therapeutics assume a completely scientific form. But, meanwhile, we know enough of the laws of life and disease to render it possible that all inquiries into the action of drugs should be conducted according to scientific method. Pure empiricism should no longer be encouraged; it has borne good fruit in its day, but its day is passed. Empiricism belongs to the infancy of science, and, unfortunately, the infancy of medicine has been long.

The author states in his Preface that the results of his practical application of oxygen "afford quite sufficient evidence" that it "may be employed as a valuable medicinal agent." Further on he gives, under the head of "Clinical selections illustrating the singular power of oxygen as a curative agent after the failure of other treatment," a list of the diseases successfully treated. Here we find "Epilepsy of 30 years' standing," "Carbuncular boils," "Chronic affection of liver and brain, with partial paralysis," "Ulceration of leg," "Disease of cervical vertebrae," "Nervo-congestive headache," "Organs of sense paralysed, general paralysis threatening,"

* On the Use and Value of Oxygen in the Treatment of various Diseases, otherwise incurable or very intractable. By S. B. Birch, M.D., &c., &c. 2nd Edition. Churchill & Sons, London, 1868.

"Amenorrhœa," "Diabetes," "Complete paralysis of lower extremities," "Chronic bronchitis, and pulmonary congestion," "Diseased lungs and liver, terminating in gangrenous sloughing," "Pulmonary consumption in two kinds of constitution," "Asthma," "Fatty degeneration of the heart," "Imminent apoplexy," "Intense neuralgia," "Valvular disease of heart," "Chronic congestion, relaxation, and irritability of the womb, with extreme spinal weakness," "Threatened senile gangrene," and several other cases all equally complex and alarming, but all yielding to the use of oxygen. We thought, as we read,—Verily, the days of miracles are not yet over! But, alas! the age is a sceptical one, or these 72 pages of wonders would win from a grateful people some national recognition for one who has introduced a curative agent so universally successful "after the failure of other treatment."

Of these clinical selections, we must say that they are worthless as evidence. When a mode of treatment is based on clinical observations, we have a right to require that each case should be most minutely taken. Every fact must be a well-observed and well-recorded fact, or it is useless for the purpose in view. While we turn away from this evidence as unsatisfactory, to the author's explanation of the *modus operandi* of his remedy, we find everywhere such expressions as "intrinsic vital power," and "the imponderable forces in the animal economy," which are to be invigorated, so says our author, "by the quasi-catalytic power of oxygen in the lungs." Stones instead of bread, from which the hungry student turns in sorrowful anger! We are sorry to have to speak thus; but our condemnation must be understood to apply not to the subject but to the manner in which it is treated. Our own experience leads us to believe that oxygen may in some cases be used with much advantage, and our regret is, consequently, greater when we find a treatise on the use of oxygen in disease written in a style which is more likely to repel than attract the earnest seeker after truth.

WURTZ'S DICTIONNAIRE DE CHIMIE.*

PERHAPS one of the most important articles in the *Partis* before us is by M. G. Salet. It is exhaustive in its scope, and commences by a consideration of the mechanical theory of heat, "*La chaleur au point de vue mécanique*;" the second is taken up with the physics of heat. In the first the author gives an account of the researches of Mayer, Joule, and others; in the second he comes to the consideration of specific heat. We have then a third part, in which heat is considered from a chemical point of view, and concludes by reviewing the labours of Andrews, Favre, Silbermann, and others, in connection with the heat given off during chemical combustion. In an able and elaborate article on crystallography, the authors (MM. Friedel and Salet) insert, under the head of "*Correspondance des Notations Cristallographie*," tables by which the notations of Naumann, Miller, Weiss, &c., are compared. We have already referred to the excellence of the illustrations of this Dictionary. It is particularly evidenced in this article.

In the article upon copper mention is made of a compound of hydrogen and copper discovered by M. Wurtz in 1845. It is formed by heating a concentrated solution of sulphate of copper with hypophorous acid. This compound, which attracted little attention at the time of its discovery, has been endowed with interest from the recent experiments of the late Prof. Graham on occluded hydrogen. The copper loses its hydrogen on heating to 55° or 60° C. The other articles of interest are—"Ceruse," "Charbon," "Chlore," "Chloroforme," "Chrome," "Colchicine," "Creatine," "Cumine Acid Alcohol, &c.;" "*Cuminique*," "Hydrocyanic Acid," "Cyanhydrique Acid."

The following account of curare may interest some of our readers:—"Curare is an extract procured from *strychnos toxifera*, and is used by the Indians of America to poison their arrows. It comes as a black extract, solid, and of a resinous aspect. Its taste is bitter. Æther extracts a fatty matter; alcohol partially dissolves it. The aqueous solution is acid and very bitter. It contains the active principle, curarine."

The curare is a very energetic poison when introduced subcutaneously, but it may be taken into the digestive tube without producing accidents. It is necessary that it should come in contact with the blood. It acts, above all, in con-

trolling the faculties of the nervous system. It is therefore remarkable that, although it is the product of a *strychnos*, it acts in opposition to strychnine, which is a tetanic poison.

WORK WITHOUT PAY.

THE discussions which have lately arisen relative to the management, medical and financial, of St. Bartholomew's Hospital, have brought into prominence a question which deserves consideration, apart altogether from the circumstances of the particular case. What is the special claim to the respect and confidence of the public of those who fill what is called "honorary" offices? In the multifarious affairs of a complicated state of society like ours, many little services of a temporary character will require attention which may be most happily rendered gratuitously. A committee formed for presenting a testimonial to some private pet or public hero, or for collecting subscriptions with a view to the mitigation of some occasional calamity, may well be administered by unpaid officials. Temporary work of a benevolent character, should not, of course, be clogged by salaries to secretaries or commissions to collectors. But when even charity itself is on a large scale, when its resources are pledged to permanent service, and when the revenues by which its operations are fed are drawn from large estates which themselves demand incessant oversight and careful cultivation, to entrust its responsibilities to honorary agents may add a superficial grandeur, and a look of completeness and consistency to the institution; but does it in the long run afford any guarantee of economical and efficient administration? Have we—has society—any right to expect any man to devote his whole time to public duties of an arduous nature and encumbered with diverse delicate obligations without claim to remuneration or hope of reward? In any case in which service is accepted on these unnatural terms does society really get what it bargains for? And, finally, has the man who undertakes a heavy business without payment any right whatever to forbearance on the part of his constituents in their judgment of the work he performs, on the ground that his office is one which bears no remuneration?

Every rule may be liable to exceptions; but, as a rule, we hold that what is not worth paying for is not worth having; and that the very springs of industry and obligation are put in peril of corruption by that system of gratuitous service, which, under various pretences, so largely prevails in our time. Let it be allowed that a gentleman who is by accident or diligence in possession of a fortune adequate to all his ideas for this life, and who prefers occupation to repose, may legitimately feel that to undertake the administration of the estates of some well-endowed charity will be alike honourable as a proof of his public spirit and gratifying to his benevolent inclinations. It will happen in nine cases out of ten, however, that this dignified benefactor will become either perfunctory or neglectful; that years of routine labour will depress his enthusiasm and deaden his sense of responsibility. And then, when, because expenditure insidiously increases on the one hand, whilst revenues insidiously diminish on the other, some critic gently insinuates that these results are the effect of carelessness at the treasury, it is likely enough he will meet censure with the plea, "I am not paid for what I do, and you have no right to call me to account." The plea is not sound, either in the logic or the morality of social obligations; but it is, as human nature is constituted, practically forcible. Men feel that to condemn an unpaid servant on a slight pretext is something like ingratitude; and thus it comes to pass that honorary offices of permanent trust are but seldom discharged with real efficiency and strict fidelity.

Moreover, a good many offices that carry the attractive designation "honorary" will prove, on examination, to be nothing of the kind. Valuable privileges belong to

* Dictionnaire de Chimie, Pure et Appliquée. Par Ad. Wurtz. "Ceruse" à "Cyanures." L. Hachette et Cie, Paris.

them. There are advantages which mere salary cannot represent—distinctions which no emoluments could purchase or secure. We have no wish to wound the feelings of the medical gentlemen who stand at the head of the professional departments of our great hospital charities, or cast any shadow upon their reputation. But how can the word "honorary," without some considerable qualification, be applied to their hospital appointments? True, they do not stipulate for regular salary, or for the payment of fees according to a fixed scale. True, they abstract nothing from the income of the institution. But they enjoy a distinction which is the most valuable advertisement they could possibly have. That distinction is secured to them, moreover, as a veritable monopoly. We have heard a great deal lately about the gross inadequacy of the professional machinery of our splendid hospital establishments. The complaints on this subject which have reached us have, we admit, been slightly querulous in tone, and somewhat seriously compromised by the influence of manifest personal resentment; but are not the complaints true in substance? It will not be pretended that if these "honorary" offices were thrown open, where there are now two physicians and two surgeons, ten of each class of perfect competency would not be at once available. But the professional value of the appointments would be thereby correspondingly deteriorated, and therefore the holders of existing offices are no friends to the wider diffusion of their obligations and labours. Nor is this all. Our great public hospitals are our great schools of medicine, and the medical officers of some of them make large revenues by the fees of the students. In their case, therefore, the word "honorary" must be understood to bear an eccentric signification.

The nation is indebted to Mr. Gladstone for introducing unpaid Ministers into the service of the State, and we objected to the plan at the time. Either Lord Lansdowne has some work to do, and is able to do it, in which case he should have required a salary, and by doing so entered the lists with other aspirants for place of smaller fortune; or he is of no use to the country, and, therefore, not entitled to the official *status*—even though that *status* may have many of the characteristics assigned by Lord Salisbury to *prestige*.—*The Globe*.

MEDICAL REFORM MEETING AT BIRMINGHAM.

A NEW ASSOCIATION STARTED.

A LARGE meeting of the Profession was held last Saturday evening, at the Midland Institute, in connection with the memorial which has already been so fully considered in our columns.

Dr. Bell Fletcher, who occupied the chair, having detailed the measures that had been taken in reference to the memorial, suggested that the time had arrived for a more thorough organization than has yet been effected.

Mr. Sampson Gamgee moved: "That the Provisional Committee of the Medical Reform Union be authorised to present the Birmingham memorial to Her Majesty's Government, in such manner as they may deem best calculated to secure the object of the memorialists." He said they had done one thing, and that completely—they had answered those who had been in the habit of saying that those who took an active part in the movement did not know what they wanted—(hear, hear). He thought those who had taken part in the movement might pride themselves upon its principles, which were not sectarian, but catholic and scientific. The object in view was simply to benefit society, and promote the welfare of the nation—(hear, hear). They had been advised by the leading men in London, and their course had been approved by the medical press. It would be a great pity indeed to let the matter drop after simply presenting the

memorial to Government. The first thing to be considered was the name to be given to the organisation, and it was proposed to call it the Medical Reform Union the only object at present being to improve the Medical Act.

Mr. Manley would second the resolution if one name were left out. A warm altercation then ensued, objection being made to any intercourse with Mr. Demsey, whose name will be familiar to our readers in reference to the Club question. The chairman read the paragraph in the memorial condemning those who lent their names to unqualified persons. Mr. Demsey called it an absurd paragraph, though he stated he had signed the memorial. He admitted having an unqualified assistant.

Dr. Foster then moved the following resolution:—"That Dr. Bell Fletcher, Mr. A. Oakes, Mr. Gamgee, Mr. D. C. L. Owen, Dr. Heslop, Dr. Johnson, Dr. Hinds, Dr. Keyworth, Dr. Lory Marsh, Dr. Boddington, Mr. Furneaux Jordan, Dr. Foster, be appointed a Provisional Committee (with power to add to their number) for the purpose of forming a Medical Reform Union on the basis of the memorial, and that the Committee be empowered to enrol as members of the Union such members of the Profession who have signed the memorial as they think fit."

Mr. Manley seconded the resolution. He said any remarks he had made were for the benefit of the society. His aim had been to correct the lukewarmness on the part of the medical profession.

Dr. Lory Marsh suggested an adjournment, with a view to make this a preliminary meeting.

The resolution of Dr. Foster was carried, and Dr. Bell Fletcher appointed chairman, Mr. S. Gamgee vice-chairman, Mr. A. Oakes, treasurer, and Mr. C. L. Owen secretary of the Provisional Committee.

SCOTLAND.

ADMISSION OF LADIES TO MEDICAL CLASSES.

WE now give—what has been unavoidably delayed—an abstract of the speeches delivered at the General Council of the University of Edinburgh, believing, that as they relate to a matter of much interest to the Profession, they are worthy of being preserved in our pages.

The Rev. Dr. PAIN, Assessor for General Council, moved that the General Council disapprove of the resolution of the University Court to admit ladies to medical study in the University of Edinburgh. After defending the course he had adopted in bringing his motion before the General Council, he proceeded to say that he was not afraid or ashamed to avow his opposition to ladies becoming members of the medical profession. He had no objection whatever to their education in the science of health. He regarded that as most desirable; he considered it as of the utmost importance that they should receive a general education, and that they should be instructed especially in the way of preserving health, and in the way of restoring health when sickness came on. But while he considered women admirably fitted for acting as nurses, and while he would train them as such to the highest extent, he would not have them licensed as surgeons or as physicians. That was what was now asked for, and that was what he opposed. And why did he oppose it? He answered—In the first place, because he believed there was no need for the admission of ladies into the medical profession. He did not believe in the stories which were so often told about women losing their health because they could not make up their minds to consult medical men. He believed that such women who lost their health in the way to which he had referred, lost it because they would not divulge their condition to their mothers, or their sisters, or elder relatives or friends. If they would divulge their condition their friends would have no difficulty in obtaining for them the opinion and advice of

competent doctors. He was persuaded that those delicate women whom they often heard of falling into bad health because they did not choose to consult men, would not consult those medical practitioners who were now seeking to be authorised. He was convinced that the demand for ladies as medical practitioners did not exist; and if there was no demand, why should they furnish the supply? He went further. He objected to the granting of degrees in the medical profession to females, because he thought there was great risk of practitioners of the female sex appearing who would enter upon very improper practices. This was a very delicate subject, at which he could only hint in such a meeting, but the details which were given of it in the Court when the matter was pleaded there were of the most alarming, he would add even of the most horrible description. He objected to females becoming practitioners of surgery and medicine, because, speaking of them generally, he held them to be both physically and mentally disqualified from acting as surgeons or even as physicians in those nerve-trying cases which doctors must constantly anticipate. They made excellent nurses in ordinary ailments, but surgeons and physicians must go far further than that. There were comparatively few women who were desirous to be recognised as medical practitioners. Granted that some of the few would do well in the profession which they desired to enter, he held that it was inexpedient to depart from well-established good rules for their sake. He had been told that the Medical Faculty was against him. He was well aware of that, but notwithstanding the great respect which he felt for the members of the Medical Faculty in this University, and for the members of the other Faculties also who had agreed with the majority of the Medical Faculty in this matter, he was not very much moved by the fact of this opposition. The Medical Faculty was not unanimous. The Nestor of the University, the remnant of the Professors of a former age who were fast passing away—Professor Christison—was opposed to the course which the other members of the Medical Faculty were inclined to follow; and some eminent Professors in other departments agreed with Dr. Christison. Nor could he forget that an illustrious ornament of the University whose retirement from the Professorial body they that day deplored, was as decided in his opposition to the movement as any member of the Council could be. He felt, therefore, that he was in good company in following the course he had taken. Besides, what did the Medical Faculty and the Senatus recommend to them in this matter a few months ago? They proposed in the University that ladies and gentlemen should prosecute their studies together in certain medical classes. When that resolution was come to, there was a petition presented to the Court signed by no fewer than 180 students against this monstrous proposal; and the University Court, he was glad to say, rejected it. But it should be remembered that though it was rejected by the University Court, it was approved of by the Medical Faculty, and by a majority of the Senatus, so that the fact of the Senatus and the Faculty being against him did not disturb him very much.

Dr. ANDREW WOOD seconded the motion. He said that one of the great arguments brought forward in favour of ladies being doctors was that women were increasing at a tremendous rate in the world, and that as it was not in our power to diminish them as we would Norway rats, that therefore we should convert them into doctors of medicine. But had it been proved that there was not sufficient men in the world to perform the duties of doctors of medicine? Was there not a sufficient supply of medical men? Why, the competition in the medical profession had arrived at such a pitch that many medical men were actually starving for want of employment. And were they to improve this state of matters by bringing ladies out of their proper sphere into a sphere that had hitherto been occupied by men? Then it was said that they should not oppose this because the University was very poor, because the Professors were poor, and that it was of great consequence that the fees to be got from the ladies should go to eke out their pitiful

subsistence. But that was a poor argument, and they should not be influenced by it. The question was, was this a proper profession for ladies? Any one who knew what the study of the medical profession was knew that there were a great many things to be encountered in the course of study that were not fitted for ladies. There was no use of being mealy-mouthed on the subject; and he must say that he could not look with any degree of comfort upon any lady whom he saw coming out of the dissecting-room. He did not think the ladies knew what they were going to encounter. Were they going to attend all the operations in the operating theatre? were they to sit for hours in the dissecting-room cutting up human bodies? These were not places for ladies. The law was a cleanly profession; let them go to the law; or if they did not like the law, let them go to divinity. He had no hesitation in saying that the teaching of women would be found to come little short of the teaching of men. Divinity was also a cleanly profession. If they sanctioned their admission to a profession which they ought not to adopt, they were unsexing the ladies. He maintained that he could not be considered as speaking against the fairer sex. He held that he was their champion. Every lady he had spoken to on the subject had most unequivocally declared that, instead of it being easier for them to consult female doctors, they were totally opposed to the admission of ladies into the profession.

Professor MASSON, in moving the amendment, said—In the interest of what I consider the right conclusion on a most important public question, in the interests of five women who are not here to represent themselves—for the credit, also, of the great University to which we belong; for the credit in part even of this city—I rise to meet Dr. Phin's motion with as dead, as direct, and as complete an opposition as I can. After referring to the progress of the movement, the discussion anent it in the University Court, and the desirability of obtaining the opinion of the General Council on the resolution adopted by the Court, he proceeded to characterise the supposed arguments used by the two previous speakers as consisting of fallacies and phrases. There are some things in the medical profession that make it unfit for women! They imagine what all women have to go through in the study of medicine—and he supposed all medical men could do that better than others—but when he employed his fancy to the uttermost in realising the most disagreeable details that belong to that profession, he could not see that he could call upon women to do very much what women had not been doing from the beginning of the world. He supposed that from the beginning of the world women had attended sick beds and nursed. He supposed that from the beginning of the world women had laid out dead corpses. He not only supposed, but knew, that women, whose names are immortal—one woman in particular—who is thought of and spoken of as the ministering angel of our time, and other women who attended her, went to the East during the Crimean war. There was no talk then in this country about the disgusting nature of their occupations, and of what they did. On the contrary, there was not a man worth the name of a man who did not have in his fancy all that disgust, even of the utmost minutiae, who did not melt that down in the purest gold of honour that he could put on the heads of those women. Again, there is a fallacy in all this argumentation which amounts to this—that they speak as if the whole feminine sex were to rush into this one profession of medicine. They speak of the profession as being overrun, and as if the whole sex were to be deteriorated and taken out of its natural bent. This is not the question. It is not whether you or I would like any woman we know or take an interest in to study medicine. The question is not about all women studying medicine. The question is, whether those particular women who want to study medicine, and who have made up their minds to study it, shall have the right to do so or not? This was no party question: it appealed to stronger principles. It was a question of right on the one hand; and they might

drive back five women from a career which they had chosen, and which they had proved themselves, as far as preliminaries went, unusually fit for. He concluded by moving—"That the General Council approve of the University Court respecting the admission of women to the study of medicine in the University of Edinburgh."

Professor BENNETT referred to the fact that the University of Paris, as well as other Continental Universities, were open to female students; and pointed out that one result of refusing admission to ladies to the University here would be to send them to the Continent for their education. The study of medicine, like the study of all other things, was not one of sex, but one of mind and one of ability; and they should be going contrary to the principles of their ancestors if they did not open their doors widely to all persons, whether male or female, in desiring to extend the blessings and benefits of education.

Principal Sir ALEXANDER GRANT, after defending the conduct of the University Court from certain insinuations which Dr. Phin had made against it, proceeded to say that the proposition which Dr. Phin advocated was one which had been well characterised by his friend Professor Masson. It was a sort of St. Simonism—that form of socialism which implied that there should be some governing body to legislate for the different professions, and who decided what person was fitted to enter a profession, and what person was not. That was the kind of system which Dr. Phin was advocating—namely, that the University was to legislate, and that a certain class of people were not to be allowed to enter the medical profession because that class of people were not fitted for it; and that it was not good for them that they should. Surely the Council might leave it to the persons themselves to find out whether they were fit to enter a particular profession. If they entered that profession and were not fit for it, they would not succeed; and, by the natural course of things, they would not continue in it. If it was not good for their characters or for the fineness of their feelings to enter into it, surely it might be left to their fathers or friends, or their own good feelings, to consider whether they should remain in it. It might be said in the same way, that women should not be allowed to act on the stage. Acting on the stage was considered in some families as not desirable for women, and therefore these women did not go upon the stage. But others did so, and succeeded in giving pleasure to their friends and doing no harm.

Dr. ALEXANDER WOOD said Dr. Phin seemed to have been oblivious of all that had been doing of late years, and appeared to be determined to maintain a position in regard to women which had been virtually abandoned by all the thinkers of the age years ago. He could understand his friend on the right (Dr. Andrew Wood)—he could understand him perfectly. He was a gentleman who seldom wrapped his meaning in mystery. He had come forward ostensibly as the advocate of the ladies, but really as the advocate of the starving members of the profession; and, seizing the door, he held it against the ladies, because there were some few medical gentlemen who could not make a living. On behalf of the medical profession, which was a noble profession, and not a dirty profession as clean as the profession of which his Lordship (the Chancellor) was so distinguished an ornament—on behalf of the medical profession he begged to vindicate them from that selfish, horrible verdict. If women were fit to enter the profession, he was sure they would bid them God-speed. Dr. Wood then went on to show that in former times there were eminent female professors of anatomy on the Continent, and that it was nothing new for women to enter upon medical studies. He was not there to say that many of the medical studies which women would have to engage in would not be disagreeable. They were disagreeable to the medical profession at present, and more particularly that branch of medical education to which Dr. Andrew Wood referred—the practice of dissection. It was disagreeable, repulsive, and loathsome in one sense, even to the male sex; but he would say this, that when a

woman considered the high object she had in view in ministering to human suffering, she would pass through it, and pass through it the more willingly that it would enable her to discharge those duties. They had been told that the female student would not be able to qualify for the profession. With that the University had nothing to do. The University had prescribed a certain course, without passing through which no man had a right to enter the profession, and the same would apply to the women; and they left it to the professors and medical examiners to say whether a woman was fitted for the task which she wished to undertake.

DR. PETTIGREW.

WE congratulate the managers of the Royal Infirmary in securing the services of Dr. Pettigrew to fill the office of Pathologist to that institution. To the medical and surgical staff the appointment will afford entire satisfaction, while all must acknowledge the propriety of so distinguished a graduate of the University of Edinburgh being connected with an institution the efficient maintenance of which is so intimately associated with its prosperity. Dr. Pettigrew is one of those whom the late Professor Good-sir inspired with a large amount of his own enthusiasm and love for philosophical investigation, and it was with a feeling of pride as just as it was honourable to him who called it forth, that he recommended his pupil's inaugural dissertation as worthy the highest honours the University could bestow. Since then Dr. Pettigrew has from time to time published in various scientific journals original investigations in human and comparative anatomy and physiology, the results of which have secured for him the admiration and respect of the scientific world, and have procured for him a place second to none as an accurate observer and original thinker. About a year ago he resigned his office as first assistant in the museum of the Royal College of Surgeons, England; the effects of incessant labour there having produced a temporary illness. The beauty and delicacy of his preparations are among the wonders of that wonderful museum. In a sphere so congenial Dr. Pettigrew will have abundant opportunities of prosecuting fresh investigations, while from the position he has acquired, and the kindly courtesy of his manner, he will attract a larger number of students regularly to attend the Pathological Theatre than at present frequent it.

MEDICAL MISSIONARY SOCIETY.—The annual meeting of the Medical Missionary Society was held on the 18th inst., in the Royal Hotel, Edinburgh—Dr. Brown, president of the Society, in the chair. There was a large attendance. The Secretary read the report of the year's proceedings, which showed the Society to be in a prosperous condition. The treasurer, Dr. Ormond, read an abstract of the income and expenditure for the past year, from which it appeared that the total income was £1,755, and the total expenditure £1,781—leaving a deficiency of £26 5s. The amount of the reserve fund at present was above £2,000.

THE meeting of the subscribers to the new Royal Infirmary, Edinburgh, was held on Friday, the 19th, when it was unanimously resolved to support the managers of the Infirmary in their proposed application to Parliament for leave to build the new hospital on the grounds of George Watson's Hospital.

UNIVERSITY OF EDINBURGH.—The University Court has recognised the lectures of Professor Huxley on natural history, delivered in London, as qualifying for graduation in medicine at the University.

ST. PANCRAS WORKHOUSE.

DR. BRYDGES and Mr. Corbitt have sent in their official report as to the condition of the Workhouse Infirmary. It appears that sometimes the atmosphere of the wards is extremely fetid, as on the 15th ultimo, when all the windows were closed. Notwithstanding that two of the windows of the wards were opened, the fetidity of the air still continued; and it appears that there were nine more patients in the ward on this occasion than on a former occasion when a visit was made to the No. 11 Ward. Part of the bad smells appear to come from a mass of sewage outside; and Dr. Brydges thinks that if care were taken as to the source whence the air is derived, and overcrowding were prevented, the Infirmary might be as healthy as any other in the Metropolis. It appears that Mr. Jabez Hogg has recently visited the wards, and found them to be in most respects as favourable to the treatment of the sick poor as most of the London hospitals. All of this we can well believe. The difficulty appears to be at the present time, that there is such an immense demand for admittance into the Workhouse Infirmary situated in our poorer parishes in London, that they are liable at any moment to become overcrowded. Nor do we see any way in which this difficulty could be obviated unless we adopted, as has been proposed, the Parisian system of central offices, where the poor, when sick, could apply for admission into some of the Infirmarys or Hospitals, and when, as in Paris, the number of vacant beds could be ascertained every day and filled up by the most worthy cases. It is clear that a glut may take place at any moment of cases of consumption or bad ulcers of the leg in any particular Workhouse Infirmary, and that the Guardians may have to choose between the denial of any further admission into their hospital, or the overcrowding which has been so much complained about of late in the St. Pancras Workhouse.

There is one point in the whole question of workhouses that we would advert to with deep-felt sorrow; and that

is, that it appears to be the present temper of many of the most leading periodicals of the day to desire to cast as much odium as possible on the whole working of the English Poor-law system. That the press should be ever vigilant to spy out abuses which exist in the system we do not deny, nay, we earnestly maintain that this is its highest duty. The provisions of the Act should be seen to be rigorously enforced, and all destitute persons applying for admission into our workhouses should be immediately admitted, whether into the casual ward or into the other department; but it is a totally different matter when we hear so much windy declamation against the whole system, and so many recommendations as have recently been made as to the necessity of affording to the poor an amount of out-door relief, which, if once conceded, would pauperise the whole community in a very short time. Do not such declaimers see that all our produce is dependent on somebody's work, and if we are to entertain the idea for a moment, that whenever a workman or workwoman begins to find toil disagreeable, some other person should continue to do this disagreeable thing in order that he or she should be unproductive, the very wealth which would support the idle for a time would soon melt away, and the whole country would become pauperised,—unless, indeed, the poor in workhouses insisted on being treated as slaves are still in some countries, *i.e.*, compelled to work hard and be fed just as the other members of society pleased in return for shelter and food.

At the time of the Socialist Revolution in France, in 1848, the cry of the leaders of the parties was the “Droit de travail.” And what was this “Droit de travail?” It was nothing more than a demand for a certain provision against starvation similar to what our admirable legislation of 1832 assured to every one of us in this country. The French have no certainty, when in indigence, that they will have any succour; and are obliged to appeal to the charitable efforts of some devoted citizens of Paris and other large towns. And with all of this, there can be no doubt that poverty is far less common and appalling in France than it is among us. Dr. Alexander Wood, too, has shown last year that the poverty of Scotland has increased since the introduction of the English Poor Law system into that country. Do not the writers, then, in our journals, who so eloquently inveigh against the evils of want of out-door relief, see that in so doing they are perhaps doing as much harm as they can to the true cause of human independence and dignity; would any of them if young and in straits like to be granted facile charity by the State? Do they not see that facility of obtaining alms is the most certain method for destroying every noble and independent sentiment in the breasts of the poor?

Labour is the source of all wealth. It ought, therefore, above all things, to be held in esteem; but if we teach our poor people the lesson which has ruined the people of Spain and other aristocratic countries, that idleness and submission to the upper classes is the chief virtue of the poor, we may look forward to the downfall of the British Empire.

UNPAID MEDICAL SERVICES.

WE hear that the Committee of the Metropolitan Free Hospital has consented to call together a meeting of

Governors, to know whether it is their wish that the Medical Staff of that Hospital should perform their duties entirely gratuitously. We fear that the Governors of all of our London Medical Charities have so long been accustomed to ask, "Why pay the doctor?" that they will on this occasion, when appealed to, say they cannot see why medical men should receive any fee for public services. In fact, we are afraid that it will require the united action of the members of the Profession to carry into effect the feeling against gratuitous public medical relief, which was so plainly evinced at last year's meetings of the British Medical Associations Local Metropolitan Branch. Some of the dispensaries of the metropolis, when the committees are composed of able men, have long seen the necessity of giving a small fee at the end of the year to the physicians and surgeons. These posts have therefore been sought after and retained by many zealous and able medical men. The names of some of the paying dispensaries are the Finsbury Dispensary, the Surrey Dispensary, the Bloomsbury Dispensary, the St. Olave's Dispensary, and one or two more.

Is there any reason why such an example should not be followed universally? We cannot see why the physicians to the different Consumption Hospitals of Brompton, Victoria Park, and North London, why the medical men of the Royal Free Hospital, the Great Northern Hospital, and many other charities, are so completely unpaid as they at present are. It may be said that these gentlemen all eagerly compete for their respective situations, in order to acquire experience and enable them to succeed in private practice, and that if they did not take these appointments they would be ignorant, and incapable of competing with their hospital brethren. There is much truth in this account of the motives which leads medical men to take such appointments; but the whole truth is not contained in it. The fact is, there is a disgraceful amount of back-stairs influence at work in the appointments made at our leading medical institutions. Instead of allowing open competition to decide the contests for the posts of physician and surgeon to Guy's, Bartholomew's, the Middlesex, or other large hospitals, there is some ineffably distressing and repulsive system of canvassing of the "Governors" which has to be gone through. The treasurers or secretaries, too, of some of these terribly abused charities, have often the power of getting some of their friends into office, and hence one is never sure, save when merit is patent and transcendent, that any gentleman, holding lucrative hospital posts, is an able man, or merely a pretender. Hence the establishment of so many unpaid medical charities in London; whilst in Paris, with the exception of one or two clinics for the eye and for skin diseases and syphilis, there may be said to be no such thing as unpaid medical services. In this respect we greatly prefer the Parisian system.

A certain number of our respected confrères, who like everything that occurs in this country (even the squalor and rags of the East end of London), because they have always been accustomed to see it in the Land of Liberty, and the Empress of the Seas, &c., say that it is a fine thing to have honorary medical officers of our charities, and that they would not like to be paid. To this argument we reply:—It is true that many persons of independent means are physicians and surgeons, and it is a pity that such gentlemen, when willing to assist in alleviating the amount

of sickness among their fellow-citizens, should not be allowed to do so gratuitously.

But such persons might do this also in Paris easily, by setting up a clinique of their own, or by competing for public paid medical posts, and then giving the amount of the fee received to the hospital or dispensary they served as medical men. The competing for such public posts in company with their poorer brethren, would show that they were fully aware of the necessity not only of being benevolent, but of being able medical men. One of the greatest educational instruments in Paris is the Concours. It makes all medical men in that metropolis of civilization on the *qui vive*, and prevents them falling into the condition of contented mediocrity so much favoured by our system of non-competition. Besides this, and this is far more important, it secures highly instructed advisers to the poor, instead of amateurs, as we have so often in our hospitals.

A man who receives even £40 a year for attending twice a week for some hours at a dispensary or hospital, feels himself bound in honour to try to give some return for this fee. On the other hand, the medical man who receives no fee at all, insensibly, unless of the very highest order of mind, glides into indifferentism, and begins to regard all his poor patients with a *poco curante* air. What matter, in fact, is it to him whether they get well or not? he is never the better if they are cured, and none the worse if they die or get worse. Those Governors of our public charities who are so blind to the motives which actuate the vast mass of mankind as not to know that persons will not take interest in what they have no interest, will perhaps ere long refuse any longer to allow anyone to take the post of gratuitous medical adviser to the poor.

Would it not be a good thing to renew the meetings in the British Medical Metropolitan Branch this winter, and to endeavour to let them gain the ear of the outside public? The Dispensary in St. Bartholomew's close has recently, after advertising in vain for some time for medical men, been obliged to have recourse to payment of its physicians and surgeons. The Farringdon Dispensary is about to do the same. Why not let the other charities in London take up this cry,—“No unpaid public medical services?” If they will but do this we believe that this bad system would, ere long, be put a stop to. Justice is a much rarer and more noble virtue than generosity.

MORTALITY IN COTTAGE MATERNITIES.

THE recent discussion upon large and small midwifery hospitals has rendered our readers familiar with Dr. Elliott's Waterford Cottage Hospital, it having been one of those selected by Dr. Kennedy to furnish a basis of calculation as to what constitutes the necessary death-rate in labour where crowding is avoided. Dr. Elliott has further dealt with this subject in a communication just furnished by him, in which he dwells especially upon the striking and conclusive results arrived at from the comparison of the earlier with the later period of his own hospital, and which has been now established for a period of 31 years and 6 months.

The contrast is very striking, and we would beg our readers to bear in mind that the early period, or that which was least satisfactory, corresponds with the more satisfactory portion of the great lying-in hospitals; whilst as the mortality in them has increased, that in the Waterford Hospital has diminished, leaving the inevitable conclusion that the changes in these respects are not due to a mere alteration in the character of metria, but to local causes in operation in the hospitals themselves; or, in

other words, to the increase of metria in the greater and its diminution in the smaller hospitals. To what, then, is the improvement due in the smaller hospitals due? Let Dr. Elliott explain this in his own words:—

“The number of deliveries from the opening of the hospital in March, 1838, to the 20th October last—a period of 31 years and 6 months—has been 3,628, and the number of deaths from all causes has been 15, and of these 5 have been caused by metria; so the total mortality has been in the ratio of 1 in 241 cases, and the mortality from metria has been 1 in 723 cases, the hospital having an accommodation for eight patients.

“The hospital has, however, had two sites or localities since its establishment. The first was occupied from March, 1838, till October, 1844, a period of 6 years and 6 months; and here the eight beds were collected into one ward. During this, the first, period 753 deliveries took place, and the number of deaths from all causes was 6, 3 of these deaths being due to metria; so the total mortality was 1 in 125½ cases, and the mortality 1 in 251 cases from metria.

“The second locality has been occupied from October, 1844, till this day. Here the eight beds are divided between two wards, four in each. The number of deliveries up to last October—a period of 25 years—has been 2,875; of these, 9 have died, 2 of the deaths being due to metria; so the ratio of mortality in this, the second, locality has been 1 in 319 from all causes, and 1 in 1,437 from metria. I subjoin a tabular view to save trouble:—

	Deliveries.	Deaths.		
First locality: During 6½ years; eight beds in one ward	753	<table border="0"> <tr> <td style="padding-right: 10px;">{ Metria ... 3</td> </tr> <tr> <td style="padding-right: 10px;">{ Other causes... 3— 6</td> </tr> </table>	{ Metria ... 3	{ Other causes... 3— 6
{ Metria ... 3				
{ Other causes... 3— 6				
Second locality: During 25 years; eight beds in two wards; four beds in each	2,875	<table border="0"> <tr> <td style="padding-right: 10px;">{ Metria ... 2</td> </tr> <tr> <td style="padding-right: 10px;">{ Other causes... 7— 9</td> </tr> </table>	{ Metria ... 2	{ Other causes... 7— 9
{ Metria ... 2				
{ Other causes... 7— 9				
Total deliveries	3,628	Total deaths... 15		

“The remarkable difference between the mortality in the two localities, especially as caused by metria, has been brought out already in a short article which I published on the subject in the *Quarterly Journal of Medical Science* for October, 1867, to which I refer you, and also, as you know, by Dr. E. Kennedy, in the discussion which he maintains in your own periodical. This contrast in the same hospital—admitting the same class of patients, under the same management, medical and other, and for so many years—constitutes the chief value of these statistics; for as to the general small ratio of mortality, it has been realised in other small lying-in hospitals, and will be in more as their number increases, which is sure to take place.

“I may add that this result was not matter of prevision or precaution. Whatever precautions we thought possible we adopted in the first locality; nor did we willingly adopt any others in the second; the division of the beds between two wards, instead of collecting them in one, was forced on us by the requirements and arrangement of the house we rented. We chose it because it was more central and easier of access than the former, and the size and number of the rooms, which obliged us to divide the beds, we thought a disadvantage. It was only the slow experience of years that discovered to us the benefit which we had neither sought for nor expected.”

Dr. Elliott is quite right in the value he thus attaches to the contrast afforded by a study of the habits of metria (for it comes to that) for a period of over 31 years in the same system of management in every respect save one; and what is that one difference upon which so marked an improvement depended? Simply, “the division of the beds between two wards, instead of collecting them in one”—a change that, he honestly tells us, “was not the result of prevision or precaution, or willingly adopted, but forced upon them by the requirements of the case—namely, the size and number of the rooms; thus obliging him to divide the beds at what he thought a disadvantage.”

We think, therefore, when the result of this simple alteration has been to reduce the death-rate in the last 25 years to 1 in 319 from all causes, and to 1 in 1,437 from metria, that it was the duty of Dr. Elliott to call the attention of the Profession to a fact bearing so strongly upon the discussion at this moment attracting so much attention, as well in the medical world as amongst all enlightened sanitarians.

Notes on Current Topics.

Society of Apothecaries of Ireland.

WE understand that at a Council Meeting of Apothecaries' Hall of Dublin, held on Friday week, a series of resolutions were brought forward at the instance of the Medical Council. The gist of these was—That a triune examining body be constituted in Dublin for Ireland, composed of members of the College of Physicians, College of Surgeons, and Apothecaries' Hall, to examine all candidates. That examination and certificate from such body be a *sine qua non* to entitle to the insertion of name on Medical Register. That the higher special titles of Physician and Surgeon be obtained by another examination by those bodies separately, and that the Apothecaries' Hall license for pharmacy only and for the privilege of keeping shop. The passed candidate of conjoint Board to be styled “*General Medical Practitioner.*” The resolutions were carried after a good deal of opposition, many of the shareholders believing that it would be a desirable reform, as enabling all branches of the Profession to co-operate without jealousy in insisting on a good education up to a certain point, which, if of a high standard, would make the further special degrees easy to all. The passing of these resolutions will lead to the downfall of the anomalous constitution of the Hall, as it will promote reconstitution on a proper basis—that is, a representative body of all its members, not merely as it is of sixty shareholders.

Health of Dublin.

IN the Dublin Registration District the births registered during the week ending November 13th amounted to 171. The average number in the corresponding week of the years 1864 to '68 inclusive was 161. The deaths were 151. The average number in the corresponding week of the previous five years was 156.

The deaths from fever amounted to 12—viz., 1 from typhus, 6 from typhoid or enteric, and 5 from simple continued fever. Sixteen deaths resulted from scarlet fever; the average number of deaths from this disease in the corresponding week of the previous five years was 6. Measles proved fatal in 3 instances. Two deaths were caused by croup, and 3 by whooping-cough. Five deaths were ascribed to diarrhoea, and 1 to dysentery. Convulsions was the assigned cause of death in 5 instances. Bronchitis caused 24 deaths, and pneumonia or inflammation of the lungs 4. Two deaths were referred to apoplexy, and a like number to paralysis. Seven deaths were ascribed to heart disease, and 2 to aneurism. Two deaths were caused by nephria or Bright's disease. Liver disease was the cause of 5 deaths. Eleven deaths were attributed to phthisis or pulmonary consumption, 6 to mesenteric disease,

and 2 to scrofula. Four violent deaths were registered; 3 were accidental, and 1 suicidal. Of the persons whose deaths were registered during the week, 7 were 80 years and upwards, and one of these, a gentlewoman, is stated to have reached the advanced age of 92 years.

A Female Student at the Dublin Medical Schools.

AT Steevens' Hospital, Dublin, a lady is attending lectures. We believe she was formerly for a short time a pupil at the Ladies' Medical College in Fitzroy square, London. It appears that she is now attending lectures on anatomy, physiology, and surgery in Dublin, and that she sits among the pupils of the hospital, who, of course, treat her with respect and courtesy. We believe that she has not as yet faced the unpleasantnesses of dissections and operations.

The Climate of Victoria.

THE *Melbourne Argus* states that attention is being drawn in different parts of Australia to the alterations which the climate is undergoing in consequence of the systematic denudation of tree-covering to which the surface of the country is being subjected. In the case of the Ballarat district, the destruction of the timber is said to have been accompanied by a corresponding diminution in the rainfall, and since 1863 there has been a more or less regular reduction—from 37·27 in. in 1863 to 17·23 in. in 1868. During the first seven months of the present year, and including two of the ordinarily wettest, the rainfall has been only 11·20 in. The Government of Victoria have, we are glad to hear, appointed an Inspector of State Forests, whose duty it will be to prevent the waste of timber and the reckless destruction of live wood, and at the same time to establish nurseries of forest trees in various parts of the colony. Action of this kind is of the utmost importance, or the climate will assuredly suffer much.

A Novel Method of Treating Naso-Pharyngeal Polypi, by M. Bonnes.

A GIRL, twenty-five years of age, of lymphatic temperament, complained of difficulty of swallowing and of breathing through the nose, and the usual inconveniences of a polypoid growth, which could be felt growing above the soft palate. There being much difficulty in getting near its root so as to have it thoroughly removed, M. Bonnes (de Nîmes) contrived a method for incision which would succeed, consisting of a thimble ring, furnished with a sharp-cutting steel nail-shaped plate. With this the pulp of the finger is free to feel the exact spot, when, by pressing the steel nail into the root of the polypoid growth, the mass is separated by a species of uprooting of it from its attachment.

Treatment of Cancroid Growths by Arsenic.

M. KUHN gives several cases illustrating the advantages of applying arsenical pastes, not directly to the surface, but to the substance of the growth. He advises the previous application of caustic potash, so as to produce an abraded or raw surface, which can then be directly acted upon by the arsenical preparation. It is to the want of adopting this preliminary step that M. Kuhn attributes the success of many cases. Without an abrasion of

the surface arsenic does not seem to exert any influence. Thus, the conjunctiva of pigeons, when brushed over with a concentrated arsenical solution, suffers no injury whatever. The following is an illustrative case:—

T. W., aged seventy, had a cancroïd tumour of the lip. M. Kuhn touched the growth with caustic potash, and then coated the raw surface over with Frère Comé's paste. The patient suffered but little pain. The eschar fell off in three weeks, and the cicatrix was perfect in five weeks.

Several others are cited where the cancroïd growth was destroyed by the use of the arsenical paste after the surface was opened up by the use of caustics.

Syphilitic Paralysis Treated by Mercurial Inunctions.

THE following (from the *Bulletin Générale de Thérapeutique*) illustrates a form of paralysis of a syphilitic origin happily susceptible of cure by specific treatment. Dr. Thomas Reade, of Belfast, many years since drew attention to this form of syphilitic lesion, and from time to time, in the pages of this Journal, typical cases have been recorded; and some remarkable in their character have been reported by Mr. Morgan, of Dublin, in the number of the Journal for Sept. 8, 1869.

A "sergent de ville," aged thirty-nine, was admitted to La Charité, November 4, 1868. He always had enjoyed perfect health, but affirms that he only contracted syphilis in 1860. He had then a hard chancre, a pleiad of indurated glands, sore throat, "patches," &c.; for these he was successfully treated by iodide of potassium and Van Swieten's liquor.

On Nov. 2, 1868, having suffered for some days previously from diarrhoea, he was suddenly affected with watery evacuations, and an intense pain in the lumbar region; just then (as he was on guard), he saw a marauder making his escape, and made an effort to pursue him, but found his limbs were incapable of supporting his weight. He was received into hospital the next day, he could walk for the two first days, but soon lost the power of motion, and was confined to bed; gradually he got worse, and complete paraplegia came on, the lower limbs being moved about by his hands and quite powerless, and gradually the arms themselves became affected, and could hardly be raised to the mouth or over the head. From the syphilitic history and symptoms, the case was diagnosed as one of reflex and syphilitic paralysis, and treated on this principle by the use of mercurial inunctions; once the patient became under the specific influence, the symptoms began to amend, and he was finally discharged in a few weeks cured, and able to walk without difficulty.

Communicability of "Charbon" by the Common Fly.

WE learn from the *Gazette Médicale de Paris* some remarkable facts as to the transmission of "charbon" by means of flies, and we cannot fail to be reminded of the danger attending the surgeons, nurses, and friends of a patient suffering from the disease. Hygienic precautions even in the trivial matter of permitting flies to swarm in our houses and about sick beds in hospitals are thus of importance.

M. Raimbert gives the result of some interesting experiments: he diluted some blood of "charbon" in water, placing it under a glass bell; in this bell he confined cer-

tain flies of the blood-sucking or piercing kind, as the horse-fly, but found that they refused the liquid, and on examining afterwards their digestive tract, no bacterides could be detected; on the other hand, the common horse-fly and meat-fly, when submitted to the same test, partook with avidity of the liquid, and when their digestive tract, excrement, proboscis, &c., were examined, large numbers of bacterides, of globules, granulations, &c., were found, and not only these, but on the wings and feet, so that not only internally, but externally, they were fully charged; when these materials were taken from the feet and wings and inoculated on animals, the disease was communicated to them, and after death numerous bacterides were discovered in the blood. The experiment is ingenious, and the question raised one of importance as showing that morbid products may in so unsuspected a manner be transplanted.

The Non-Degeneration of Vaccine Virus.

At a late meeting of the Académie de Médecine, M. Guichard brought forward the subject of the degeneration of vaccine virus. As he had most extensive opportunities during a very long practice in a populous district, he stated positively that he had vaccinated 15,000 cases, and his father, to whom he succeeded, had vaccinated largely, the sum total being 21,000 cases. He does not give any credence to the theory of degeneration of the virus, which has been lately so much discussed, but believes it as efficacious as ever; but, at the same time, he counsels that the option of human or animal vaccine should be given when practicable.

Dialectical Society of London.

At a recent meeting of this Society, the Chairman, in speaking of the examinations of the so-called phenomena of spiritualism, &c., remarked that although he individually did not take any interest in this question, and would not take any part in the investigation of so-called spiritualistic manifestations, still that the spirit of the Society was so completely that of the widest toleration for all opinions, and that it so much desired (in which it might show an example to other societies) the freest discussion of even the most unpopular topics, that it could not prevent any of its members taking up their time with its discussion. The question of the Irish land tenure and its effects in causing over-population and indigence was then discussed.

Dr. C. Drysdale thought that the Irish Land question was one of the most important ones which society in this country had ever been called upon to consider and to legislate for. There would never, he added, be any real public tranquillity in this kingdom until poverty and misery were less common in the agricultural districts of Ireland, England, and Scotland. Dr. Gairdner, of Glasgow, for instance, had recently stated at the meeting of the British Medical Association at Leeds, that the overcrowding and poverty of Glasgow were never so great as at present, on account, in great measure, of the crowding into that city from the country districts, a crowding which he (Dr. Drysdale) added was common to all our large cities, and which was chiefly attributable to our detestable land laws. The land laws of the whole kingdom were bad enough, but those of Ireland quite accounted for the

unequalled misery which had so long existed in that most interesting country. In France, no less than 5,000,000 persons owned the land; in England, only 30,000; in Ireland, 8,000. It was distressing to witness the amount of misery in agricultural districts, and the thoughtless way in which the Irish cottiers and British farm labourers gave birth to swarms of poor ill-starved children, whilst in France the peasant proprietor was thoughtful, prudent, and careful, to a degree, as to the number of his family. It was affirmed, indeed, that in many parts of France, the peasants "limited their families to two children." He recommended the introduction of the Prussian Land Banks into Ireland.

Dr. Edmunds was in favour of the State receiving rents from the peasants directly, and thus ensuring that the rents were what the peasants could really pay and not only promise to pay.

Mr. Reid thought that the present proprietors of the Channel Islands and France showed how much better this holding of land was than the cottier tenancy of Ireland, or the farm-labourer system of Britain. There was not such rapid breeding down to starvation in France as in this country, which was at present greatly over-peopled.

Mr. Rigby Smith spoke in favour of some amount of communism in land, and against the primogeniture customs and entail customs of this country.

Mr. Geary recommended expropriation of the Irish landlords and raising up of peasant proprietors, as recommended by Mr. Mill; and Mr. Quelch thought that England also wanted a great change in land tenure.

Chairs of Hygiene.

WE are glad to find that the teaching of Hygiene is now getting into vogue, and rejoice to find that King's College has followed the good example of University College, and appointed Dr. Guy to deliver a series of lectures on this important branch of medical science. Drug medication is not in its most flourishing epoch, and without some thorough knowledge of the natural history and hygienic treatment of disease, we become stranded in scepticism and altogether careless as to treatment, however much time we may expend on diagnosis. We hope ere long to hear from some of our learned professors of hygiene what we should drink, and whether we should smoke or not; whether marriage of near relations is dangerous; what diseases are hereditary, and whether celibacy is or not dangerous to health.

Professor Huxley.

THE lectures to ladies, delivered in the South Kensington Museum, are, we believe, a great success. Mr. Mill's words of encouragement to ladies, to try all things and hold fast that which is good, have borne fruit.

Special Hospitals.

It appears that the Eye Hospital at Leeds is to be merged into the general hospital of that city. If this could take place at many of our Metropolitan hospitals we should not require to have quite so many institutions; but, on the other hand, is it not just possible that the plan of having small buildings set apart in various parts of the town for special purposes, may be at once more hygienic and not less economical than the fabrication of

special departments in big and overgrown hospitals? Again, is it necessary that a patient coming to some charity for a slight disease of the eye should run the chance of taking some fever or contagious disorder whilst traversing the passages of our large hospitals, such as Guy's and St. Bartholomew's? The eye departments in many of our hospitals are rather scurvily treated. It was so at University College Hospital, and the same used to be the case with the obstetric department of that hospital. So that, after all, special buildings for special diseases are, perhaps, not a bad thing.

Admission of Licentiatees to the Fellowship of the Royal College of Surgeons, Ireland.

THE Council of the Royal College of Surgeons of Ireland have had under consideration at their last meeting a proposition for the admission to the Fellowship of the College on a greatly modified examination of Licentiatees of many years' standing.

As we have already announced, the Council after discussion decided almost unanimously that, at present, it would be inadvisable to seek a new Charter for the College. They are, therefore, forbidden, even if so minded, to abrogate the Fellowship examination in any case, for it is strictly enjoined in the Charter. They are, however, empowered to alter the examination as they may see fit. In the case of Licentiatees of rank in the Profession it has for some time been the habit to make the examination a merely nominal test, but it was felt that objections must lie against any arrangement which make an examination stringent or otherwise at discretion. A resolution was submitted that—

“Licentiatees of the College may, at the expiration of ten years from the date of their Diploma, be admitted to examination for the Fellowship, provided they produce such evidence as shall be satisfactory to the Council that they have conducted themselves honourably in the practice of their profession; and that the Examiners certify that they have examined them upon the subjects of the Thesis, or six Reports of Medical or Surgical cases, submitted by them.”

This resolution was not adopted, but the debate was adjourned, and we understand that it will be then submitted in another form.

A New Phase in Legal Psychology.

A TRIAL has recently taken place in America which has given rise to so much medico-legal question that the *Boston Medical Journal* has devoted to its consideration the greater part of its last issue. The prisoner, Samuel Andrews, a deacon of his Church, had by his own confession, killed one Holmes. Andrews belonged to a family in which hereditary insanity was rife, but he himself never showed the least evidence of aberration of mind. His relations with Holmes were most intimate, and he was aware that he had been named as a legatee under Holmes's will. He, the prisoner, deposes to several attempts made by Holmes to commit an unnatural offence, which, however, he had successfully resisted. On the evening of the homicide, Holmes asked him to take a walk in a lonely road, and, the prisoner alleges, having thrown him down, proceeded to repeat the attempt. Being held down by the throat but having free use of his arms and hands, he seized a stone and struck his assailant wherever he could reach him. From that moment he, Andrews, lost all conscious-

ness. Of what he did then he has no knowledge, nor can he tell how long he remained in this unconscious state.

The next that he remembers is, that he found himself standing, swinging his arms, holding two stones in his hands, and throwing them at Holmes. He had a feeling of great exhaustion, as if he had passed through great labour. His hat was off. His hands and clothes were bloody. Holmes's dead body was before him. He adjusted his clothes, and returned to his house. From that day (Tuesday) until the following Monday he kept the matter secret, and then made the confession of which the foregoing facts are the substance, fearing, as he said, an accusation of murder. The examination of the body showed that the head was almost beaten to pieces, and as many as twenty-seven bloody stones were found near it. There was no obvious motive for the murder, and a large sum of money which Holmes had with him was untouched.

The question arising is, could the prisoner have committed the deed in a paroxysm of insanity lasting only a few minutes, he having shown no evidences of madness before or since? This enquiry involves the possibility of transitory lunacy, and consequently, of irresponsibility for any one act without regard to the general question of sanity. The jury found a verdict of manslaughter, a decision which would seem to be hardly worth anything. If the prisoner's story be true the case would be one of justifiable homicide,—if false, of murder.

St. Bartholomew's Hospital.—Special General Court.

THE governing body of the above institution held a “special general court,” on Monday last. The chair was occupied by H.R.H. the Prince of Wales, who opened the proceedings by a speech bearing on the matter for which the Court had been called, and concluded it by calling on Mr. Foster White, the Treasurer, to read his answer to the allegations made against the management of the institution.

The Treasurer proceeded to make an elaborate statement, which occupied more than two hours in delivery, and read at its conclusion a voluminous letter addressed to him by the medical staff.

We were present during the entire sitting, and as statements were made of vast importance to the Profession and to the governing bodies of kindred institutions, we defer a full report of the proceedings until our next issue.

Is Anything being Done?

IN the truly characteristic method with which such matters are commonly dealt with in Great Britain, the St. Pancras Guardians are now in course of being treated. If an accident takes place, or a passenger is robbed and murdered in a railway carriage, or an insurance swindle explodes and ruins hundreds of families, or a more than usually flagrant instance of trade roguery comes to light,—the newspapers become turgid with letters and leaders, the public works itself into a froth of indignation, the authorities look on with dignified *nouchalance*, the evolution of gaseous rhetoric abates by degrees, the public becomes again *blasé* on the subject, and the frauds or abuses again gather force and proceed as before.

The St. Pancras Workhouse is just now the ferment which affects the public nostrils. Every one is horror-

struck, and the newspapers perspire again with laborious declamation and abuse. In a few weeks, doubtless, the public will be, as the Philosophic Liberals would say, "educated up to the St. Pancras Workhouse system," and will care nothing about the matter. The papers will cease to sell, and the condition of things which has been pushed under the public eye for many months never observed by anyone will pass on into futurity unaffected by the temporary notice it attracted.

Last week, six more inquests were held, for which the jury considered that the St. Pancras Infirmary was responsible.

We forgive our contemporaries for their fervid, if empty, ebullition, but we suggest the inquiry, *Is anything being done?* If the Guardians be virtuous and Dr. Ellis a maligner of innocence, should they not be duly and officially whitewashed without further delay? If Dr. Ellis be a knight errant in defence of the miseries of the poor, and if the Guardians are really their slayers, why are they not extirpated by one stroke of the official pen? Surely they deserve no tenderness or consideration, and surely the public and the dying pauper wants something more than sickening details of death, quires of official phrases, and an endless vista of lawyers' bills.

Mr. Griffin.

It seems that this gentleman, whose name, we trust, will long be remembered with affection by all reformers of the Poor Law Medical Service, was a man of substance and of wide culture and sympathies. This, we may remark in passing, is usually found to be the case with persons who endeavour to ameliorate the condition of their struggling brethren. In order to sympathise well with the sufferings of others a mind enlarged by general culture is almost requisite; and in order to do much work towards the amelioration of the social condition of our fellow men, a certain amount of means is almost indispensable in order to enable the reformer to secure a little of that most precious perhaps of all the constituent parts of wealth, leisure. Now-a-days the poor man is worn out by an incessant struggle from morning to night to gain a living, and wants time to think clearly for others.

Apoplexy and Drunkenness.

THERE is another case registered of mistake by the police of the former of these affections for the latter. There is nothing very extraordinary in this, since, of course, the occurrence of drunken lethargy is so infinitely more common than that of apoplexy. But all doubtful cases of drunkenness should at once be taken to some hospital or police medical man.

Hospital for Women in Soho-square.

ANOTHER case of questionable charity in our strange metropolis. There is, it seems, to be a large number of beds opened by money subscribed by some charitable person, for the reception of patients suffering under uterine disease, able to pay some small sum for their bed and board while in hospital. *A la bonheur*: but why not call this a private hospital for the reception of paying patients? Why mix up charity and business in this way? Why not be paid for what service we can perform to our patients?

Miss Nightingale.

WE hear that Miss Nightingale has offered to superintend the nursing department of the new Pauper Hospital at Highgate. Truly, without noble-minded and intellectual women like her, we men folks get on very badly, and bungle our charities most woefully.

Relapsing Fever.

THE frequency of the famine fever in the metropolis is now becoming quite alarming, and several hospitals are about to be re-opened to receive the sufferers from this most contagious complaint. We apprehend that it is clearly traceable to the miserable condition in which the metropolitan poor have lately been plunged by the collapse of trade, and by the overcrowding and low wages consequent on over-population. We well remember the same fever when attending hospital in Dublin shortly after the great famine of 1847. A large emigration would probably check it for a time; but, of course, the radical measure would be to reform our land laws, and thus have the comfort of the Jersey peasant instead of the squalor of our agricultural labourers.

St. Pancras again.

MR. ROGER ERKYN writes to the *Times* to say that he has visited the Infirmary of this Workhouse at or about four o'clock in the morning very recently, and has found that there is certainly a very great amount of fetor in the wards, which do not give more than 600 cubic feet to each patient. After this he walked to the new St. Pancras Infirmary at Highgate, and found that space has been allotted so as to give a minimum of 900 cubic feet to each patient. Both of these measurements are under the mark, probably, which ought to be aimed at by all hospitals for surgical and bad medical cases. One bad leg in a ward may vitiate the atmosphere, or some unfortunate sufferer from cancerous ulceration may cause fetidity of the air in the largest wards. The system of large wards in large hospitals has been so much written about recently, that it seems like "beating out the chaff" to refer to it again; but it is evident to us that the great mistake has been in building such a costly place at Highgate.

The Mansfield Guardians.

WE have a letter from Mr. Diver impugning the accuracy of our information, and consequently the justice of our remarks in a recent article founded on his letter in the *Midland Gazette*. The letter reached us too late to insert in full this week, but we refer to it here lest he should think us reluctant to hear both sides. He says the Guardians intend making a new district. Mr. Diver admits he applied for the appointment, though not in the terms named. The only question of interest to the Profession is whether Mr. Turner desired still to serve under the Guardians, or whether the appointment would not be taken by him.

THE Court of Examiners of the Society of Apothecaries after next June will require every candidate for the licence to have been a clinical clerk for six weeks and to have attended the class examinations of the Professors in their Schools.

Epidemic Fever in East London.

At the meeting of the Poplar Board of Guardians, on Friday evening, a communication was read from Dr. Gray, the medical officer of the Union stating that there was every appearance that the eastern districts of the metropolis were likely to be visited by an epidemic fever during the coming winter, and that he much feared the accommodation of the London Fever Hospital would be taxed beyond its capabilities. He suggested that permission should be sought from the Poor Law Board to reopen the North Street Infirmary for the admission of fever patients. The Chairman remarked that the Poor Law Board would doubtless give their consent, as they had approved arrangements made by the Metropolitan Asylum Board with the Fever Hospital for the provision of extra accommodation, as well as for temporary accommodation being provided on the site at Hampstead already acquired by that Board for hospital purposes. It was resolved that a copy of Dr. Gray's letter should be sent to the Poor Law Board.

The Cholera at Peshawur.

We regret to learn that cholera is still at Peshawur. Up to the 3rd instant there had been cases daily in most of the native regiments. Nor were the European corps quite clear of the pestilence.

Fifteen deaths in the city were reported on the 1st, and twenty-five on the 2nd instant.

H. M.'s 104th are now in camp upon the Cherat Hill.

We hear further of the deaths of two officers in the persons of Dr. Bell of H. M.'s 36th Regiment, and Captain Chalmers of the 19th B. C., who succumbed there recently to the prevailing epidemic. The former, well known for his kindly manners and courteous bearing, died at his post in the discharge of his onerous duties, in the very prime of life, and amid the tears and regrets of all who knew him, and it is painful to hear that his wife and family are said to be on their way out from England to rejoin him in this country. The disease was said to be in abeyance or declining, and not a day too soon if all we hear of its ravages be true. It is said that the 36th alone has lost upwards of 120 men, and that the 104th lost 75, besides a number of women and children, amounting in all, we hear, to some 95 or 100 souls. Our correspondent did not know the numbers who had succumbed in the Artillery, but if they are in any proportion with the losses just referred to, they must be considerable, and we do not think we are at all over-stating the figures when we say that some 250 Europeans have died under the influence of the terrible scourge with which that station has been recently visited. If things go on as at present, it will soon become a question whether it will be worth while keeping the country at all under such circumstances and at such a sacrifice.—*The Delhi Gazette.*

Chloral.

THE new researches on chloral undertaken by MM. Bouchut and Personne confirm the conclusions of M. Liebrich on the subject. In a late *séance* of the Academy of Sciences, M. Bouchut had communicated a work which goes to prove that the contradictory results obtained by different experimenters were due to the state of purity or impurity of the substance employed.

Chloral requires to be preserved in the state of a solid hydrate; with the agent in that condition the results are rapid, evident, and energetic. They are those of the most tranquil hypnotism, and almost absolute insensibility.

The action of chloral is that of chloroform; longer, however, in being produced, and enduring for a longer period. There follows in some patients muscular and mental agitation resembling drunkenness, but in no respect disgusting or disagreeable. In most cases it is sleep, rarely accompanied by hyperæsthesia, but most usually by strongly manifested anæsthesia.

The anæsthesia is in proportion to the quality; and at a dose of 2 to 5 grammes it is complete, and permits of the application without pain of cauterly, of Vienna paste, or even the extraction of teeth.

As a therapeutic agent chloral is a perfect sedative in the dreadful sufferings of nephritic colic or toothache. In a word, it is the best of the anæsthetics given by the stomach. Finally, it is the most prompt and effectual remedy in chorea.

M. Bussy, in commenting on M. Bouchut's researches, said that he had observed that chloral, when administered to dogs, is partially transfused into chloroform under the influence of the alkalinity of the blood.

Pharmacy in Ireland.

THE Pharmaceutical Society of London were recently moved that steps should be taken to assimilate the laws which regulate the practice of pharmacy in Ireland and Great Britain respectively, and has decided at its last general meeting to submit the subject to a sub-committee for consideration and immediate report. This course is, we presume, the result of the movement which acquired so much strength last winter amongst the Pharmaceutical Chemists of Ireland. The Irish contingents have shown themselves to be a very influential and energetic body, and their representatives have had great weight in the Pharmaceutical Society. We shall look with much interest for the report of the committee, for on it will depend, in the greatest degree, the future of Pharmacy in Ireland.

Chinese Therapeutics.

THE Chinese divide medicinal substances into heating, cooling, refreshing, and temperate. Their *Materia Medica* is contained in the work called the *Pen-tao-scang-mou*, in 52 large volumes, with an atlas of plates. Most of our medicines are known to them and prescribed, also mineral waters, with which the country abounds. They also have animal magnetizers, called *Cong-fou*.

They divide their prescriptions into seven categories, viz.:—1st, the Great Prescription; 2nd, the Little Prescription; 3rd, the Slow Prescription; 4th, Prompt, or Through-by-daylight Prescription; 5th, the Odd Prescription, for fools, madmen, hypochondriacs, and the hysterical; 6th, the Even Prescription, for the wise and good; and 7th, the Double Prescription, for those in the family way.

Each of these recipes is applied to particular cases, and the ingredients that compose them are weighed out with the most scrupulous accuracy.

The physician never pays a second visit unless sent for

WE learn that changes are contemplated in the arrangements of the *Pharmaceutical Journal*. This periodical has grown to such a condition of plethora that no alternative presents itself, but either to "bantingise" it or divide it into halves. This latter course will be probably adopted. Already a Committee of the Society is at work on the arrangements, and we may shortly expect to hail the issue of our contemporary as a weekly.

WE hear from Edinburgh that the five ladies attending Dr. Hughes Bennett's class are most diligent students. They are reported to sit in the class-room without their bonnets; we suppose in this proclaiming their intention to be on an equality with the other sex, who in this country take off their hats. In Paris, as far as we can remember, the students frequently keep on their hats; so there this formality would have been spared the lady students.

THE death is announced of Sir James Prior, who was for many years in the medical service of the navy. He served off Greenland and in the North Sea, in Africa, in the East Indies, Brazil, and on the eastern coast of Africa. He was staff-surgeon of the Chatham division of Royal Marines, and was appointed in 1843 Deputy Inspector General of Hospitals and Fleets. He was the author of a life of Burke, a life of Goldsmith, and some medical works. Sir James Prior was born in 1790, and was knighted in 1858.

THE University Court, of Edinburgh have adopted the following regulations for the education of women in medicine in the University:—1. Women shall be admitted to the study of medicine in the University. 2. The instruction of women for the profession of medicine shall be conducted in separate classes, confined entirely to women. 3. The Professors of the Faculty of Medicine shall for this purpose be permitted to have separate classes for woman. 4. Women not intending to study medicine professionally, may be admitted to such of these classes, or to any such part of the courses of instruction given in such classes as the University Court may from time to time think fit and approve. 5. The fee for the full course of instruction in such classes shall be four guineas; but in the event of the number of students proposing to attend any such class being too small to provide a reasonable remuneration at that rate, it shall be in the power of the professor to make arrangements for a higher fee, subject to the usual sanction of the University Court. 6. All women attending such classes shall be subject to all the regulations now, or at any future time, in force in the University as to the matriculation of students, their attendance on classes, examination, or otherwise. 7. The above regulations shall take effect as from the commencement of Session 1869-70. The Chancellor has sanctioned the regulations in terms of the Universities (Scotland) Act, 1858.

[The University Court, it will be observed, have in these regulations recognized and intended to provide for the disability which all decent women must have in attending classes with men. They are to have separate classes, and the professors are to charge £4 4s., or a higher fee, subject to the approval of the Court. Supposing there be only one, two, or half-a-dozen female students, what professor will give his full course for four, eight, or even twenty-four guineas?—ED. MEDICAL PRESS AND CIRCULAR.]

Correspondence.

THE MULTIPLICATION OF MANKIND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—One cannot help admiring the supercilious air with which your correspondent F.A.S.L. condescends to "sincere devout people, who never have been far from their native place." But I am at a loss to discover how the fact of a man's having travelled could be of advantage to him in discussing the question to which I called attention in a late number. I can understand how a northern tour might have benefited the King of Siam, who believed it impossible that water could freeze, or that a whole sea could harden to such a degree as to admit of an army marching across it. But when a person argues for the possibility of a thing, to say to him, You have not travelled, seems absurd.

Again, F.A.S.L. complains that "sincere devout people" rely upon what is written. Surely he does not pretend that he and his anthropological friends have a perfect and direct knowledge of things, past and present, which makes them independent of the testimony of others. It strikes me that we both place confidence in records, he preferring those of recent discovery, which a few years may prove to be of equal value with that memorable record regarding Mr. William Stumps; and I choosing still to regard with reverence those whose authenticity is attested, and placed beyond all reasonable doubt, by the history of more than thirty centuries. But I may be allowed to observe in all courtesy, that if F.A.S.L. interprets the records with which he deals in the erroneous manner in which he has interpreted my letter, the sooner he gives up his archeological studies, and ceases to shake the faith of those who are unable to discern how weak his arguments are, the better both for himself and for the world at large.

That 450 years, according to the Septuagint and Mr. Stuart Poole, elapsed between the Flood and the accession of the Pharaohs, was allowed by the Duke of Argyll, not started by me; and I merely controverted the Duke's assertion, that it was impossible such space of time could suffice for the propagation of the human species, from the small number who left the ark, to the immense multitudes necessarily supposed in the formation of great monarchies. For this purpose I brought two arguments, the one of fact (the multiplication of the Israelites in Egypt), the other of computation upon a fixed rate of increase, which, allowing only six children to each pair, dispensing with plurality of wives, and reducing the average age of death to thirty, yet showed that in 450 years, no less than eighty-five millions might have sprung from Shem, Ham, and Japheth, and their wives. As to the former argument, F.A.S.L. first sneers at the record from which my information is derived, though St. Paul (to mention no higher name) bears me out in my belief and interpretation of it (Gal. iii. 17); he next shows his ignorance of that record by placing Abraham instead of Jacob at the point at which the family began to enlarge, that is, at the beginning of the 270 years during which (as I had said) the progeny of one man increased so as to be capable of furnishing an army of 600,000 men; and he then assumes, without any positive warrant, but simply to cast discredit upon Holy Writ, that for 600,000 fighting men there must have been in all at least 3,000,000 persons. Strange to say, however, he seems afterwards to grant the fact, but, as if taking a weapon from his antagonist's armoury, ascribes the wonderful speed at which the Israelites at this time multiplied to miraculous interference, another assumption for which he has no warrant whatever. I grant that a special providence guarded the interests of this chosen people; but that is vastly different from the miraculous. A miracle is an act, to account for which the laws of nature are totally insufficient; strictly speaking, it is a thing that demands our belief in a Higher Power, being a sign of His presence. But I nowhere read that the laws of nature were subverted to admit of the extraordinary increase of the children of Israel, or that the people multiplied faster than nature would allow them. Therefore, in seeking to explain the supposed difficulty regarding the more immediate descendants of Noah, I have not availed myself of the "easy solution" now kindly proffered me, namely, that they multiplied miraculously.

With regard to my second argument, I am glad to find that F.A.S.L. is not so unreasonable as to consider the number reached by the calculation impossible. And when he styles

the rate of increase which I took as the basis "preternatural," he can only mean, I imagine, above the average of the present day; for the experience of everyone in the profession will confirm my statement, that it is not more than Nature can attain, but is fully within the bounds of possibility naturally regarded.

I can, Sir, without much demur grant that the kingdoms mentioned by your correspondent actually did exist, and not only exist, but flourish; nay, I can add as many more of equal size on to the list, and yet reasonably question, whether the whole round comprised more than *eighty-five millions* of persons. But when F.A.S.L. would have me believe that the several quarters of the globe were at that early period, "for ought that is known to the contrary," almost equally populated, I think he is asking too much, and I am cautious enough to hesitate; because, to the best of my knowledge, the world is not thoroughly overspread with human beings even in this advanced age. I can grant that the African negro has undergone no very marked change during the last four thousand years, and yet doubt whether he may not have undergone such change during the few hundred years immediately preceding (the Septuagint would allow 1000, which F.A.S.L. has carefully concealed); for I see no reason why the effects produced by acclimatization should be perpetually augmenting, or why racial divergencies of all kinds might not have increased more rapidly in the early days than now. Of course that which in the book of Genesis is briefly described as the *confusion of tongues*, but which must have referred to some great and miraculous influence upon the cerebrum and cerebellum of each individual whose language was altered, variously affecting their development, will be scouted as a myth; therefore I will not pursue the subject. But by way of conclusion regarding the question of population, allow me to ask F.A.S.L., whether, in face of the rapid strides which nationalities make in the present day, if I have such difficulty in accounting for the slow progress of the number of the world's inhabitants from the accession of the Pharaohs till now, when my computation (supposing the number to be at present 1,300,000,000) would make it to be only about fifteen times as great,—it is possible for him, with any degree of reason, to make this progress to have been still slower, by assuming that the number in the first instance exceeded that which I allow?

The Biblical chronologies may be "utterly incompatible" with the so-called "facts of ethnology," though he who affirms it makes a very sweeping assertion. But the records contained in the Pentateuch are *in themselves* acknowledged facts of very old standing, to explain the existence of which, and yet evade their force, will require much harder logic than that of any archaeologist the world has yet seen; and as some require the years of the Patriarchal age to be lengthened, whilst others with voice as loud demand that they be shortened, I shall leave these persons to settle their differences amongst themselves, and in the meantime adopt the motto very wisely enunciated, *In medio tutissimus ibis*.

Trusting that you will pardon the length of my letter, and again favour me with insertion,

I have the honour, Sir, to remain,

Your obedient humble servant,

DANIEL BIDDLE, Surgeon.

Kingston-on-Thames: Nov., 1869.

CARBOLIC ACID OIL IN SCARLATINA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The favourable notice you have bestowed on my little pamphlet on "Scarlet Fever and its Prevention" induces me to hope that you will allow me to submit to the Profession the following thought, which shall be stated in the fewest possible words:—

Dr. Budd, some months ago, in a letter in which he published his mode of treating scarlatina by inunction with "olive oil slightly impregnated with camphor," introduces this parenthesis—"Current views would perhaps indicate *carbolic acid* as a fitter adjunct."

Reflecting on this intimation, and calling to mind the properties of carbolic acid, and, more particularly, Dr. Lemaire's assertion that it "acts anæsthetically," and "as a healing agent in burns." I was led to compare in my own mind the symptoms of a severe burn with those of scarlatina.

I was, of course, aware that the *causes* were different; but

my thought was, *not* to strike at the root of the evil, but to relieve such symptoms as might admit of relief by an external application, and, while relieving these, to destroy the vitality of the scarlatina germ at the very moment of its making its appearance on the surface of the skin.

Turning, then, to the reported cases of scalds cured by Professor Pirrie and Dr. Alan Wilson with carbolic acid oil, I found *more* symptoms in common than I had at first thought of, which strengthened my hope that the carbolic acid oil might be found serviceable in scarlatina.

As many non-professional men are readers of your Journal, permit me to enumerate the "symptoms in common" with which I was struck:—Hot skin; burning pain; eruption, red or otherwise; constitutional disturbance, producing shivering, nausea, vomiting, thirst; pulse frequent, feeble, irregular; nervous system, depression, prostration, exhaustion.

Now, all these symptoms, when arising from burns, are, according to Lemaire, Pirrie, and Wilson, controlled in a remarkable manner by the application of carbolic acid oil. And my suggestion is, that they *may* be thus controlled when occasioned by scarlatina poison. "Could the carbolic acid oil act as a repellant?" then occurred to me. My answer was, "No; carbolic acid is an alcohol; indeed, by some Continental chemists it is designated phenic alcohol; and the effect of alcohol applied to the skin is to stimulate the vessels and to cause a flow of blood to the surface."

The proportion, then, alone remained to be considered. This appeared to me to be a question for the medical practitioner to determine. In wounds it is generally used in the proportion of 1 CA to 4 olive oil; Professor Pirrie, in burns, 1 CA to 6 olive oil; Dr. Wilson, in burns, 1 CA to 30 olive oil and lime-water.

I am, Sir, yours faithfully,

Leeston, Great Malvern.

FREDERICK SMITH.

POOR-LAW MEDICAL OFFICERS' WIDOWS AND ORPHANS SOCIETY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In 1864 I suggested, through your Journal, the necessity of establishing a Poor-law Medical Officers' Widows and Orphans Society, on the ground that no existing means are sufficient to adequately assist the widows and orphans of such members of Poor-law Medical Officers as have not been provided for according to their position in society. Since that period some improvements in the condition of Poor-law Medical Officers have taken place, and they are thereby now better enabled to meet the annual expense of any fund that may, on full consideration, be deemed necessary to effect this purpose. Besides, public confidence has been lately shaken in public insurance offices, as has been well shown by Dr. Smith, of Donaghmore. Under these circumstances, I take the liberty to suggest that a communication be opened, on the part of the Poor-law Medical Officers at large, with the Chief Secretary, requesting his consideration of the whole subject after being fully explained to him; and when considered and communicated with by those who act for these medical officers (and, it is to be hoped, by the Poor-law Commissioners, whose opinion should be had early on the question), that he will bring in a *Government Bill* with the necessary provisions. If this Bill be approved by the thousand (nearly) of Poor-law Medical Officers—a great and a good act will be done, and each of these officers will have made some provision for his family, even though he may not be able to leave them in affluent circumstances.

I am, Sir, your obedient servant,

DENIS PHELAN.

DOES THE EXISTENCE OF ANY FORM OF MATTER AS A SOLID, A LIQUID, OR A GAS, DEPEND UPON THE VARYING ELECTRICAL CONDITIONS OF ITS COMPONENT PARTICLES OR MOLECULES?

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Although I am aware that, in a strict sense, the above problem scarcely comes under the range of those branches of Science with which we, as medical men, have more immediately to do; yet, as the collateral sciences are so nearly allied to our special pursuits, and we owe so much to them, you may,

perhaps, kindly find space in your valuable journal for its insertion. Restating the proposition, "Does the existence of any form of matter as a solid, a liquid, or a gas, depend upon the varying electrical conditions of its component particles or molecules?" for my own part, I must confess, I believe the reply to be in the affirmative, taking as the grounds for my assumption the apparent analogy that exists between the electrical phenomena of attraction and repulsion in bodies charged with unlike and like kinds of electricity, and the supposed similar properties, said to be inherent to the atoms or molecules, in the three different conditions in which matter presents itself to us; namely, the solid, the liquid, and the gaseous. It is a *dictum* in natural philosophy, that matter is composed of indivisible particles, which are termed atoms, or molecules, and that these atoms are endowed with two properties, viz., attraction and repulsion; further, it is laid down as a law, that according as these powers are in a state of equilibrium, or preponderate the one over the other, we obtain matter in one or other of its conditions.

It is evident, then, that any change from the one condition to the other, *i. e.*, of the solid to the fluid, or, more properly, liquid, and the liquid to the gaseous, necessarily depends on a disturbance in the existing relations of these properties.

The immediate, or rather the appreciable agent in producing this disturbance is *heat*; but the question presents itself at once to our notice, does *heat* possess an inherent power of causing bodies to repel one another? If it can be answered in the affirmative, then must the subject matter of this paper fall to the ground. If not, where must we seek for an explanation of the phenomena? The correlation of forces, or, putting it in other words, the action of one force, exhibiting itself in new groups of phenomena, according to the medium through which it acts, seems now to be so clearly established that it is unnecessary for me to dilate upon it. The experiments of Grove and others are sufficient to prove that *heat*, under certain conditions, becomes converted into *motion*, chemical action, and electricity; *light* is converted into *heat*, *chemical action*, *electricity*, *magnetism*, and *motion*; and *electricity* is converted into *motion*, *light*, and *chemical action*, in short, from any one form of force any of the others can be obtained by supplying the conditions necessary for the exhibition of their phenomena. It is in this correlation of forces, then, that I think we find the explanation of those transformations from one condition of matter to another.

I do not think it altogether a visionary supposition to assume, that heat acting through the medium of that form of matter about to undergo change in its condition, becomes changed into electricity; and that this electricity being of a like kind, if carried sufficiently far, forces the molecules to fly apart in obedience to well-established laws.

Trusting that the above ideas, crude as they are, may be thought worthy of a place in the columns of the "MEDICAL PRESS AND CIRCULAR."

Believe me, dear Sir, truly yours,

JOHN W. MARTIN, M.D., M.Ch.Q.U.I.

Medical News.

THE MIDDLESEX HOSPITAL MEDICAL SOCIETY.—The first ordinary meeting of this venerable Medical Society took place on Thursday, November 11th, Dr. John Murray, President, in the chair, when Dr. Robert King read an excellent paper on "Cells and Cell Development."

SCIENTIFIC CATALOGUE.—*Nature* states that the great "Catalogue of Scientific Papers compiled and published by the Royal Society," has now reached its third volume; a fact which we have much pleasure in announcing. In this the names of authors are carried on from GRE to LEZ inclusive, so that the compilers are nearly half-way through the alphabet. We congratulate them on their good progress, and can promise them the cordial appreciation of scientific men all over the world, to whom the work will prove of inestimable value.

AMONG the recently published State papers of the American Government, is the annual report of the President of the National Academy of Sciences.

HERE are two extracts from *Nature* which show how zealously science is being cultivated in New Zealand. From accounts of the last meetings of the Wellington Philosophical

Society and New Zealand Institute which have reached us, it is clear that good scientific work is being done at our antipodes, much of it in Dr. Hector's laboratory. The most interesting result recently obtained is the isolation of the poisonous substance in the Tutu plant. Many experiments made for this purpose during the last six years, both in the laboratory of the Geological Survey and by chemists in Great Britain, failed to discover the poisonous ingredient of the plant. A short time ago, Mr. Henry Travers collected for the Museum a large quantity of ripe seeds of the Tutu (*Coriaria ruscifolia*), and on these Mr. Skey has recently experimented. He has discovered the poison to be a greenish oil, unaffected by, and insoluble in, water and mineral acids, but soluble in acetic acid, ether, alcohol, and chloroform. This oil is combined with a red-coloured resin, which is insoluble in ether, by removing which the poisonous oil was obtained in a pure state. The quantity of the poison contained in the seed is 12 per cent. of the weight. A similar oil has been detected by Mr. Skey to be the active poisonous element in the Karaka seed (*Corynocarpus laurifolia*), which will account for its having hitherto escaped detection; and he suggests that the discovery might lead to the detection of the active principle of many poisonous European plants that have hitherto eluded research.

ANOTHER item of New Zealand news is that the result of all Dr. Hector's investigations into the geology of the islands is, that New Zealand must be considered as, on the whole, well supplied with mineral fuel. The most valuable description of coal is certainly confined to limited and not very accessible areas; but still there is nothing to prevent their being profitably worked for the supply of the steam service. The great point for congratulation, however, is, that throughout almost every part of the islands, coal of a practically useful description is to be found within a short distance.

PROFESSOR GRANT, the director of the Observatory in the University of Glasgow, has printed two letters, which he has addressed to M. Leverrier, on the authenticity of the documents respecting Newton, communicated to the Academy of Sciences by M. Chasles.

GLASGOW AND ABERDEEN UNIVERSITIES' ELECTION.—CLOSE OF THE POLL.—The voting in this election terminated on Friday at four o'clock, having lasted five days. At the close the numbers were:—

	Glasgow.	Aberdeen.	Total.
Mr. E. S. Gordon	1045	1075	2120
Mr. Archibald Smith	981	635	1616

Majority for Mr. Gordon, 504.

Out of an available constituency of about 4000 there have voted 3736. Mr. Gordon's majority in Aberdeen at last election, when he unsuccessfully opposed Mr. Moncreiff, was 196, and he was in a minority of 243 at Glasgow. This time his majority in Aberdeen is 440, and the Glasgow minority has given place to a majority of 64.

THE LATE DR. AITKEN.—On Friday a feeling of general regret was experienced in Glasgow when it became known that Dr. W. Scott Aitken, M.B.C.M., had died in the Infirmary on the previous night. The deceased had just completed a six months' attendance as visiting surgeon at the Infirmary when he was seized with typhus fever, to which he fell a victim after a fortnight's illness.

ABERDEEN DISPENSARY AND LYING-IN INSTITUTIONS.—The Directors of the Aberdeen Dispensary have purchased from the Directors of the Female Industrial School, the property in the Guestrow, presently occupied by them, for £720. There would be room, it is believed, in the new premises for carrying on the Lying-in department of the institution in a much more efficient way than the Directors have hitherto had the means of attempting; and as the working out of that department has lately been under consideration of the Directors, in connection with the recent appointment of Dr. Inglis, Professor of Midwifery in the University of Aberdeen, to be physician-accoucheur to the Dispensary, the acquisition of the premises in question will be most opportune.

SUDDEN DEATH.—On Friday morning Dr. George Stokoe was found dead in the bed-room of his house, Chapter-row, South Shields. He was found kneeling by the bedside, his hands clasped, and his face lying on the clothes. He was 44 years of age. He had been suffering from bronchitis and the cause of death is supposed to be congestion of the brain brought on by convulsions. He leaves a widow and a child about twelve years of age.

SOME CASES IN WHICH THE HYPODERMIC INJECTION OF MORPHIA WAS EMPLOYED WITH GOOD RESULTS.

By JOHN BARCLAY, M.D., C.M., Banff.

1.—ANGINA PECTORIS.

JEMIMA L., aged thirty-four, married, was very delicate in childhood, and when about eight years of age had a fall from a table, which, she says, injured her back, and produced a tendency to spinal curvature; and the dorsal region now shows a gradual and not acute curve directly backwards. After arriving at the age of ten, however, she enjoyed good health, and this continued up to about the month of May, 1867, when, being some fourteen weeks advanced in pregnancy, she was very suddenly seized one night, about half-past eleven, with great pain, and a sense of constriction at the præcordial region, radiating across the chest, accompanied with intense difficulty of breathing, and a feeling of impending dissolution. This attack lasted a whole night, and, though the medical man in attendance tried various things to relieve her, none of them did the slightest good. She has herself no recollection of what was done, for about half an hour after the seizure she became unconscious, and remained so until eight o'clock in the morning when she regained her senses, and by degrees recovered, the fit wearing gradually off. She remained pretty well for about eight days after this, at the end of which time a dirty reddish brown discharge began to flow from the uterus. This continued first for five days without being accompanied with any pain, and then other three days with slight labour pains, the whole ending, some eight or nine days from the first appearance of the discharge, and sixteen or seventeen days after the attack of the angina, in a miscarriage. A midwife attended during the abortion, and a medical man examined the fœtus afterwards, but he gave no opinion as to its age, the pro-

bable period when it had died, or what had been the cause of its death. Some three weeks after this, being still rather weak from the previous illness, she had another, but much lighter attack. Mixtures of various kinds were prescribed and taken, but none of them was followed by the slightest benefit. The attack gradually wore off after ten or twelve hours' duration. Then in about other three weeks she had a most severe attack, and I then saw her for the first time when at the height of it. It was the most awful paroxysm I have ever seen; she had been ill for several hours, and sat in bed supported by some of her friends, her face livid and swollen, lips of a dark blue colour, eyes deeply suffused, she could not articulate a word, not the slightest pulsation was to be felt at the wrist, nor could any vesicular murmur be heard in any part of the chest, only large moist râles everywhere. The heart's action was tumultuous, but the pulmonary râles prevented the cardiac sounds from being heard. Indeed, she seemed to be dying. I, however, ordered a large and powerful turpentine stupe to be applied all around the chest, a mustard emetic and stimulants. These, the people thought, gave her a little, but only a very little, relief. It was about eleven o'clock in the forenoon when I first saw her. I called for her again about half-past two on the following morning, and she was then beginning to recover. She was conscious and could speak, but denied having any recollection of what had passed after the first hour of the attack. Her recovery was a very tedious one.

In the month of September following, having a sister one of the nurses in Chalmers's Hospital, Banff, she obtained admission into that institution, and while there had an attack almost every eight or ten days till the end of October. The first two attacks Dr. Manson treated by venesection, with perfect and almost immediate relief, but the third and subsequent attacks were not relieved in the slightest degree by it. The amount of blood taken on these occasions was eight, or at most ten ounces. In the beginning of November she had a very severe attack, for which she was bled, but with extremely little benefit, and great congestion of the lungs remained after the attack had passed away, causing a very slow recovery. After this and one or two other severe attacks, she brought up some

blood. Immediately after this seizure Dr. M. inserted a seton under the left breast, which was kept in for four months, and from the period of its insertion up to the 12th of July, 1868, namely, between eight and nine months, she never had an attack at all. During this period she was in the best of health, she was what she called "perfectly right in every way." Somewhere about the middle of March she became pregnant, however, and about three and a half months after she was suddenly seized with what promised to be a very severe attack. I was called on the evening of the 12th of July to see her, and her sister, who came for me, told me she thought it would be a most severe attack, as bad as any she had ever had. Remembering how very little good had been derived from the exhibition of remedies of various kinds, and the failure of the venesection in the more recent attacks, it then occurred to me to try the effect of the hypodermic injection of morphia. I accordingly sent for the instrument, and injected under the skin of the thigh fifteen minims of a twelve grains to the ounce solution of morphia, that is, three-eighths of a grain. I remained, resolved to watch the effect. In ten minutes she was able to lean back a little, in fifteen she was able to lie down flat and to speak freely, and in thirty minutes she was perfectly relieved. At midnight she continued quite well.

July 13th.—Says she feels perfectly well, but somewhat tired and sleepy. No abnormality of the pulmonary or cardiac sounds.

July 14th.—She this morning brought up a mouthful of blood by coughing, but feels quite well. Pulse 80, regular as regards frequency, but as to force a little hard and sharp in the beat. Bowels open, urine clear, eating well and sleeping well, no cough, no abnormality of the cardiac or respiratory sounds, unless, perhaps, that the first sound of the heart is louder and sharper, and heard over a larger space than usual. No bruit or friction sound of any kind. Ordered nothing but the repetition of the injection of the morphia, if required.

Now I think there can be no reasonable doubt but that the attack which preceded the abortion in May, 1867, with the disturbance of the circulation accompanying it and no doubt depending upon it, had caused the death of the fœtus, and its consequent expulsion from the uterus seventeen days after. The occurrence of the bloody discharge and the other symptoms of abortion only eight days after render it all but certain that the angina was the cause of the death of the fœtus, and so I was exceedingly anxious to see whether the prompt cutting short of the attack at this time would prevent a like result. She had now, according to her own calculation, reached the sixteenth week of her pregnancy, which closely corresponds with the time at which the attack of angina came on in her first pregnancy. Matters went on quite well until the 11th of August, when I was called at midnight to see her. Before I reached the house, she had been ill for about an hour. She was quite blue in the face, and nearly unconscious; she was sitting bolt upright in bed, resting on her hands on the bed, her shoulders touching her ears, when spoken to could speak only one syllable at a time, and that with extreme difficulty; her look was agonized, the paroxysm awful to behold; no pulse could be felt at the wrist or temple, but the heart was beating tumultuously, 150 per minute; no respiratory sound could be heard, in fact, nothing could be heard in the chest whatever, except the heart-sounds; and there was no bruit. I injected the same quantity of the morphia solution as on the previous occasion, and watched its effects. In five minutes she could speak with ease, in ten she could lie down, in fifteen she said she was nearly relieved, and in half an hour perfectly well.

August 12.—Feels quite well.

August 21.—She had no symptom of pulmonary congestion after this attack, no symptom of foetal death or of abortion, in fact, no bad symptom of any kind. After this I enjoined her upon no account to allow the attack to

go on so long before sending to have the morphia injected, but to send the moment she felt the attack beginning.

November 5.—Had a very severe attack to-day, was ill nearly two hours before she could send, no one having been present with her until some person called for her by chance. Dr. Marson went at once and injected seventeen minims of the morphia solution, namely, approaching to half a grain of morphia, and with the usual amount of relief, and as rapidly as before. She felt quite well after this attack.

November 24.—About twelve o'clock noon to-day an attack came on. Before it she felt the foetal movements distinctly. Dr. Manson happened to call about one o'clock and told her to keep quiet, and if she became at all worse, to have the morphia injected by Dr. Brown, House-Surgeon to Chalmers's Hospital, who could be on the spot, if necessary, in a few minutes. She continued to get worse and worse till about six o'clock in the evening, when some neighbour happened to look in upon her and found her in this state. Dr. Brown was immediately sent for, and when he came, which was within five minutes, he injected seventeen minims of the morphia solution, with the same rapid and perfect relief as usual. But after this she felt no foetal movements. Besides, she felt ill, was constantly sick and vomiting, was annoyed by a frequent hard cough, with shortness of breathing, and considerable œdema of the legs. I did not see her at all during or after this attack, but she continued in a rather unsatisfactory condition till November 28th, namely, four days after the above attack, when about six o'clock in the morning she felt labour pains commencing. These continued to increase in frequency and severity up to half-past twelve o'clock noon, when she gave birth to a still-born female child. Dr. Manson, who was present at the birth, considered that the infant had not been far from maturity, and according to the woman's own calculation, in three weeks more she would have arrived at the full period of her pregnancy. Her recovery promises to be somewhat tedious, as considerable pulmonary congestion resulted from the last attack, and this is being slowly got rid of.

Now, the history of this patient, whom all medical men who had seen her admitted to be the most severe and most alarming case of angina pectoris they had ever witnessed, and who had been treated in a variety of ways as regards the paroxysms with so little success (for all treatment, unless by bleeding, and that beneficial only during two attacks, seemed useless), seems to suggest the following remarks: First, that a most severe attack of this disease can be rapidly cut short in the easiest and most simple manner by the hypodermic injection of a sufficient amount of morphia. Trousseau speaks of atropia used in the same way retarding seizures of angina and diminishing their violence, but nothing could have been more perfect than the relief afforded in the above case. Besides, morphia is a much safer and more pleasant substance to use hypodermically than atropia. Second, that the derangement of the circulation accompanying and resulting from these attacks was sufficient to produce the death of the fetus in each of the two pregnancies. It would appear, however, that the duration of the attack for an hour, or even two, was not enough to bring about this, for one or two attacks lasted as long as this without any bad result, whereas, in the first pregnancy, the duration of the attack which preceded the miscarriage was a whole night, and that preceding the last miscarriage not less than six hours. Indeed, I think it probable that had this patient sent earlier and got the morphia injected within even two hours of the commencement of the attack, the death of the fetus would have been averted, and she might have gone on to the end of her pregnancy safely, and have given birth to a living child. It is not at all likely that the morphia had anything to do with the child's death, for such a result would have been more reasonably expected in the earlier months of pregnancy.

(To be continued.)

ON A NEW LIQUOR ERGOTÆ.

By EDWARD LONG, M.R.C.S. and L.A.H.

In some correspondence with Dr. Waring Curran, on therapeutics principally in connection with pharmacy, he mentioned to me that he had been for a long time studying the actions and uses of ergot of rye, and had in practice experienced much inconvenience from being compelled to rely solely on the fresh powder made into infusion extemporaneously in the ordinary way, for want of any other reliable preparation of it. The same idea must have frequently occurred to every man in midwifery practice, as it must be most unpleasant and undesirable for a physician to have to turn pharmacien at the patient's house, perhaps in the sick room, not to mention the delay, the more so as the female portion of the community have become quite familiar with the whole process, with the result that instead of ergot becoming thereby a popular remedy, it is quite the reverse. They don't like it in any sense; it is disagreeable and nauseous to the taste, and they have a prejudice against it, from hearing that it is a very active, and it may be dangerous drug in unskilful hands, no doubt exaggerating, after the manner of the sex, all they have heard.

It would, therefore, obviously be a great desideratum if a medical man could carry with him a condensed preparation of it, which would be neither objectionable in taste or appearance and at the same time be perfectly reliable and keep well.

Being anxious to advance the cause of therapeutics ever so little, and at the same time gratify my friend, Dr. Waring Curran, I turned my attention to the subject, and trust the result will be satisfactory to the profession.

I believe the general feeling and experience is, that the only known reliable preparation of this substance, when its most characteristic effect on the uterus is required quickly and surely, is the extemporaneous infusion alluded to, which proves one thing, that water or an aqueous fluid is the best menstruum to extract its active principles. A spirituous tincture, also, is believed to have some virtue, and of the extract got by evaporating it, the same may be said. The officinal "Extract. Ergotæ Liquidum," of which much was expected, has disappointed many. The ethereal tincture and oil may be dismissed entirely—at least, I infer so—as they have fallen out of use in this city.

This is about all that is known of it in point of fact; the published analyses do not throw any light on its active principle, and merely show that its efficacy depends on the mode of arrangement and combination of its elements, without defining what the resultant is, as we so frequently see in the analysis of organic substances. As these analyses have been made by very able chemists, it is not likely that any further efforts in that direction will add to our stock of knowledge.

I accordingly decided to act on the information supplied by medical observation and experience, taking the infusion as the best of all. Glycerine, I thought, would extract all that is soluble in water, and from its well-known preservative properties, retain it in an active state. I therefore digested ergot freshly powdered, in glycerine for ten days, frequently shaking it. On straining this off, it was found to be of deep purplish colour, as thick as treacle nearly, and the marc quite soft and pulpy. This marc was then digested in spirit for ten days more, pressed off and filtered, the resulting tincture distilled off till it became the consistence of syrup, and then added to the previous solution.

I intended weighing the residuum after each process of digestion, but through an oversight the spirit was added before I could test the solvent properties of each menstruum. I shall, however, do so carefully in future experiments.

The "fluid extract" formed of these combined solutions I find to be exactly equal to the volume of glycerine

employed, and each drachm represents half a drachm of powdered ergot, and may be considered a dose.

By this process I believe all the active properties of ergot should be obtained in a very desirable form; it is sweet, concentrated, and should be permanent. I would suggest that it be kept in graduated or drachm (ʒj) bottles, to avoid measuring under unfavourable circumstances.

My object in writing this paper is, to place a preparation of an indispensable medicine in the hands of medical practitioners, with some confidence that it will not disappoint their reasonable expectations. Should it realise these expectations, there will be little difficulty in making it quite palatable, if there be not some objection to doing so, lest, from its resemblance to treacle, accidents might happen.

Several medical friends to whom I communicated my idea, have tried and are trying it, but it is obvious that a more extended trial than any obtainable by such means, is necessary to establish its therapeutic value.

As I don't practise I have nothing to add that would be of value. I have omitted to enter into any chemical details, as they would be wearisome and little edifying to the majority of your readers, who have little time for them; but I have thought it right to let them know what they were invited to adopt, instead of appealing to them by advertisement, as is the fashion now-a-days.

ON THE OVER-POPULATION QUESTION.

By F.R.C.S.

TRULY we are launched upon a very wide and curious question in our medical journals now-a-days. The Profession is asked by the editors of its journals to sit as a jury upon the question as to whether we may be said to be overpeopled in this kingdom; whether the law of Malthus, that mankind tends to increase so rapidly as to cause poverty and early death among the poor, is true or not. In fact, it seems to us that, *volentes volentes*, the Dialectical Society's debate has drawn us poor doctors into the fierce battle which has so long been carried on outside of our ranks. What, it may be asked, have medical men to do with the theory of Malthus? Is not their business to cure disease as it arises, and to be able to perform surgical and other operations so as to restore our patients to as much health as is compatible with the lesion they may be suffering under? What have we to do, it may be said, with the causes of prostitution? Our business is to cure venereal diseases, not to prevent them. And what have we to do with the causes of poverty? That is a question for statesmen, not for us.

There is some truth in all of these remarks. The family physician's, or general practitioner's, or the operating surgeon's time is entirely occupied when they are in full practice, in attempting to remove any diseases that come under their notice, not in reasoning upon disease in general and whence it arises. But it must be remembered that there is now a rather large portion of our own body whose position, as medical officers of health, &c., renders the discussion of such topics quite imperative. Such gentlemen, unless they well understand the causes of the overcrowding and poverty which it is their business to witness in the daily carrying out of their duty, are apt to be bewildered by the apparent impossibility of doing much so long as the population under their charge is so poor and so unable to comply with the judicious advice which they try to inculcate upon them as to the necessity of plenty of fresh air, cleanliness, and good food. The writer in the *British Medical Journal* of Nov. 13th knows well, from his study of the works of Malthus and Mill, that the cause of much of our social miseries is the

Hospital Reports.

UNIVERSITY COLLEGE HOSPITAL.

THE patient operated on for popliteal aneurism by Mr. Erichsen the other week by tying the external iliac is progressing favourably. The tumour in the popliteal space has disappeared. The patient, also, whose external iliac artery was tied for aneurism in the bend of the groin, is doing well, and may be said now to be out of danger, we suppose. On Wednesday, the 17th November, the only operation performed by Mr. Erichsen was the division by means of a bistouri caché of the strictured orifice of the urethra in a man of about the age of fifty-five. The operation was performed by passing the instrument into the urethra beyond the stricture, and then cutting outwards, the patient being under chloroform. Mr. Erichsen mentioned that he believed the cause of the stricture was the existence at some previous date of an urethral chancre. These chancres, he observed, usually leave most serious strictures after them.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.

MR. COUPER has now under his care a very well-marked case of astigmatism in a young man of about the age of twenty, who came complaining of considerable difficulty in performing his work on account of imperfect vision. The patient, an engineer's apprentice, had very defective sight for distance, and although able to read small print, could not do so for more than a few minutes without pain in the eyes; the print then became dim, the letters appearing to run together. The existence of astigmatism was suspected from the form of the globes, which was most peculiar. Instead of the ordinary spherical condition, with the horizontal and vertical diameters equal, each globe appeared flattened vertically, so that the horizontal diameter exceeded the vertical. This was apparent when the upper and the outer equatorial regions were exposed in succession by causing the eye to look first downward and then toward the nose. The comparative flatness of the upper region was obvious.

Mr. Couper, under whose care the patient came, showed us his ready method of demonstrating the presence of mixed astigmatism by means of a concave mirror of thirty inches focus. He takes advantage of the well-known facts—1st, that the fundus of an eye that is hypermetropic (*i.e.*, that has the principal focus of its media placed behind the retina) can be seen as an erect virtual image; and, 2nd, that the fundus of a short-sighted eye can be seen as an inverted aerial image. In mixed astigmatism the media are myopic in one plane (generally vertical), and hypermetropic in the opposite plane; and Mr. C. demonstrates the presence of both an erect and an inverted image in the same eye by selecting two objects in the fundus (usually vessels), seen by means of rays diverging in the horizontal and in the vertical planes of the media respectively. The presence of both images is conclusive of the existence of mixed astigmatism, and the next step is to measure it and determine the required optical correction. The use of cylindrical glasses to correct this want of similarity in the horizontal and vertical meridian was thus clearly indicated; and after some trials it was found that a convex cylindrical lense of 16 inches focus for the horizontal meridian, conjoined with a concave cylindrical lense of 1-30th focus for the vertical meridian, corrected to a great extent the vertical error of astigmatism. This is the normal kind of astigmatism.

A patient at Mr. Couper's desk presented in the left eye an almost perfect paralysis of all the muscles of the orbit; when the other eye was moving the paralysed

unequal race which is constantly being maintained in such countries as ours between population and the means of subsistence. He is fully aware of the enormous importance of the "Law of Population" called the "Malthusian Law," that in favourable circumstances our race is able to double its numbers in from twenty-five to thirty years. But, whilst he knows all this, it appears to us that our author is not sufficiently versed in the details of this important question, to avoid falling occasionally into some fallacies. In the first place, then, he says that "It is perhaps almost a necessity that there should be in all communities rich and poor, and that the latter should suffer their own peculiar evils. . . . The social problem (he adds) is not so much to do away with poverty as to find out the best way in which the rich and poor may live together to mutual advantage." Well, if the great problem of our day be not to remove the terrible poverty which surrounds us, for example, in Ireland, in our large towns, &c., we ask, what is the problem of our time? If poverty, as it is well known to all whose opinion is worth a moment's consideration, is the most common cause of infantile mortality, of consumption, of fever, of contagious diseases, and of that nest of venereal diseases, prostitution—if bad food and overcrowded dwellings are the cause of so much of the ills of even our most civilized countries,—why are we to be told that the removal of poverty is not the great problem of our day? Show us another problem as great.

But the writer of the article in question has a remedy for the evils of over-population, so he does not care much about it. The earth, it seems, is so vast, that we have nothing to do with the question *just now*, and especially in our tight little island. Have we not, he says, Australia, (12,000 miles away) and the United States and Canada to run off to? Give up your groaning about over-population at once: be off and take all the miserable with you to these promised lands! In short, our author looks to emigration as the panacea for over-population. Oh, Mr. Doctor: is this all you can do for your poor patient? Can you only recommend for his disease a foreign climate? Is there no hope for our old countries but by rushing forth over wide oceans to far off shores? Read the works of Chalmers, and see how well he shows up the fallacies of that chimera, emigration. Why, if our race can double itself in twenty years, if Europe were to take the advice of our *British Medical Journal* author it would require to send off some 250 millions to America and Australia every twenty years, and this only to keep our numbers stationary. If Great Britain and Ireland *went in* for this "prescription," we should have to send abroad annually one and a half million of our people. At whose expense, pray, Mr. Doctor? at yours and mine? Are we not already almost eaten up by poor-rates and taxes? Or why should a person with a small French family of two or three children be compelled to send out to America or Australia the large family of his less provident fellow-citizen? Are you prepared, in short, to say that early marriages are to be the sole prescription for sexual errors, and for the prevention of venereal diseases, without accompanying your prescription by an injunction to young couples to breed slowly? Are they to breed as fast as they please, and are we and others to send out all their children at the public expense? Answer us all of this. Do you not see that such a flotilla as would be required to send forth one and a half million of persons annually would reduce us all to the most abject misery at home, and, alas! would be the source of immense suffering to the unfortunate hosts who were thus shipped off or transported from their native shores, willy-nilly? And all of this, be it remarked, because our writer detests and abhors evidently the prudent conduct of the French, who are prudent enough to "habitually limit their families to two children." Well, if people are never to live happily at home in old countries, we say, the problem of the removal of poverty is insoluble: but the French are content with two children to a family, and do not emigrate!

organ remained as still as if it were a dead eye. Another case where the paralysis of the *motores oculi* was not quite, but nearly as complete, was seen by Mr. Lawson. Any person attending the practice of the Moorfields Ophthalmic Hospital for any time must be struck to see the amount of cases of inherited syphilitic disease of the eye: that is, the number of cases of total or partial loss of vision in patients with the pegged teeth, and other marks of that disease so well and conclusively pointed out by Mr. Jonathan Hutchinson. Thus we have recently seen two cases of cataract in young persons operated upon, when the peculiar teeth pointed to the cause above mentioned, and, in addition to these we have seen several cases of iridectomy, of lachrymal abscess and other diseases of various kinds in patients labouring under hereditary taint. We do not know that we have at all remarked the same thing in the practice of specialists in Paris, or in any other continental city.

Literature.

BILLING'S PRINCIPLES OF MEDICINE.*

To take up a book by Dr. Billing is to be forcibly reminded of the genuine work that has been done in the promotion of medical science in the last generation. It is next to impossible for us to realise in imagination what was the state of our art when the now venerable teacher began his career. We are carried back at once to thoughts of Cullen, Broussais, Brown, Rasori, when these and a few others stood out as the only lights in the darkness, and even they rather dazzled than guided. Dr. Billing became Physician to the London Hospital in 1822. Clinical lectures were then unknown in London, and he began them at once, as well as *post-mortem* demonstrations in the dead-house. The London Hospital has ever since maintained its position in the front of clinical work, and is not likely to let it fall.

Dr. Billing's work originally consisted of only about 130 pages, and great credit was accorded him on every hand for the skill with which he had condensed what he had to say into so small a compass. We first made its acquaintance at a later date, but even in our youth it was not half the size to which it has become expanded in the new (sixth) edition. If we say that every successive edition has received the general approval of the press, we barely express the debt due by the Profession to Dr. Billing for the work he has so well done. He has furnished a generation with a set of well-reasoned "principles" in medicine, which in days of superficiality and the worship of disjointed facts goes far to prove that we have yet minds among us who can grapple with the phenomena of disease in the true spirit of philosophy. Yet let it not be thought our author despises facts. Few works abound more in them; but then he uses his facts, instead of abusing them—reasons upon them, instead of merely repeating them—and, so doing, teaches his readers the one necessary lesson, to think. His is, therefore, a book to read through and through, to study, to master, and to think over. Yet there is not a more interesting work to merely dip into, for on every page some thought, some fact, some suggestion may be found which strikes the attention and leads the reader to pursue the subject. It is a great point with the author that he is, so to say, always speaking clinically. The consequence of this is, that therapeutics is with him no dry detail of remedies and their uses; nor does the art of medicine consist in certain kinds of routine practice. He is not given to hypothesize much, though he may reason from the known to the unknown with the confidence of one who has found his judgments right. Still, the work abounds with practical therapeutical suggestions, and these have the immense value of not being mere guesses, but deductions from premises already established. How infinitely preferable such "Principles" to the blind following of routine, or to the fancies so often hazarded!

* First Principles of Medicine. By Archibald Billing, A.M., M.D., F.R.S. Sixth Edition. 1868. London: Bell and Daldy.

Subcutaneous.

A NEW SUBCUTANEOUS ASPIRATOR.

AN instrument, to which the foregoing name has been given, has been presented to the Imperial Academy of Medicine, Paris, at its meeting of the 2nd inst. Its inventor, Dr. Dieulafoy, communicated at the same time the following note as to the objects which the instrument is intended to serve:—

"The Subcutaneous Aspirator appears to me to fulfil two principal conditions: firstly, as a means of diagnosis; secondly, for treatment. We know how difficult it is to recognise sometimes the presence of a purulent depot concealed under muscles or aponeuroses in the centre of such regions as the neck or iliac fossæ, or situated deep in such organs as the liver or kidney. The observer is necessarily undecided as to the presence and nature of the fluid, which does not for some time declare itself either by swelling or fluctuation. It was for the purpose of elucidating these doubts that the exploring trocar has been devised. But that instrument carries with it its own condemnation, being, at the same time, too large and too small. Its size is considerable compared with that of the fine needle, used for subcutaneous injection; yet, in spite of its considerable diameter, it hinders frequently the escape of liquids if they be at all dense.

"To remedy these difficulties I have constructed long canulæ so fine that the most delicate organs may be traversed by them without being injured more than by acupuncture needles. This trocar is introduced in search of the supposed liquid, a vacuum is easily produced with the piston, and the operator is at once informed of the presence, seat, and nature of the collection. This means of exploration is specially applicable to cysts, and all serous, hæmorrhagic, purulent, or urinary collections.

"As a means of treatment the aspirator serves many purposes. It will evacuate an articular abscess without the introduction of a single bubble of air, and with an opening so small as to be incapable of producing any ill result. Would not analogous treatment be applicable to pericardial effusions? Would it not be available for removal of urine in case of retention of liquid in encysted pleuritis and in congestive abscesses?"

"The evacuation of the fluid may be rendered continuous by means of the double stopcock, and if an injection—tincture of iodine or alcohol—is necessary, it may be made at the same sitting, and without displacing the instrument.

"The use of the instrument has been also suggested for the removal of the gases which accumulate in intestinal obstructions, and which greatly impede the return of a hernia."

One detail of construction is strongly insisted on by the inventor. When the stopcocks have been closed, and a vacuum has been created by the withdrawing of the piston, it may be locked at the top of its course by a slight turn to the right. Thus, the needle having been first introduced, it will be sufficient to attach the aspirator and open the cock, when the liquid will at once rush into the barrel of the syringe without the least movement on the part of the operator.

The instrument is manufactured by Messrs. Robert et Collin, of Paris.

SCOTLAND.

DEATH OF PROFESSOR PENNY OF GLASGOW.

WE are sorry to have to record the death of Frederick Penny, F.R.S., Professor of Chemistry Anderson University, Glasgow. For a short time his health had been rather feeble, although he had continued to lecture up to the 11th of November. No immediate danger was anticipated, but about nine o'clock on the evening of Monday, 22nd November, while conversing cheerfully with his medical adviser, he was seized with a severe spasm of the heart, during the continuance of which he died. Professor Penny was born in 1817, so that he was in the 52nd year of his age. He studied chemistry in the London Apothecaries' Hall, under Dr. Henley; and such proficiency did he acquire that in 1839, at the early age of 22, he was chosen to fill the chair of Chemistry in Anderson University, rendered vacant by the removal of Dr. Gregory to Aberdeen. He arrived in Glasgow a perfect stranger, but, backed by introductions from the late Professor Graham, he soon made his way. He found the Anderson University at a very low ebb, especially in his own department; and it will be sufficient to mention, in order to show how successfully he devoted himself to the duties of his chair, and how highly his lectures were appreciated, that while in his first year he enrolled 87 pupils, during last session, the number of his laboratory pupils was the greatest, save in one instance, attending in any laboratory in the kingdom, and the attendance on his popular class during the same session, rose to 541. As a medical jurist Professor Penny had acquired a deservedly high reputation, and his name will ever remain associated with the singularly philosophical and beautiful physiological experiments for the detection of certain alkaloids when used as poisons, where purely chemical tests fail. All will remember how wonderfully his powers were displayed in this respect in the Pritchard case. As a consulting and analytical chemist, Professor Penny enjoyed, probably, the largest practice in Scotland; and it is worthy of remark, that however complicated the case might be, his evidence was always appreciated, and he generally succeeded in carrying along with him those even to whom his opinion was adverse. By his untimely death the University with which he was connected has lost one of the most distinguished and popular of her Professors.

MEETING OF MEMBERS OF THE MEDICO-PSYCHOLOGICAL ASSOCIATION.

ON Thursday, 25th November, a meeting of the members of the Medico-Psychological Association was held in the Hall of the Royal College of Physicians, Edinburgh. The chair was taken by Professor Laycock; and there were present Professor Balfour, Dr. Skae, Royal Edinburgh Asylum; Dr. F. Skae, Stirling District Asylum; Dr. Howden, Royal Asylum, Montrose; Dr. Howden, Haddington District Asylum; Dr. Addison, Idiot Asylum, Larbert; Dr. Grierson, Roxburgh District Asylum; Dr. Clouston, Cumberland County Asylum, Carlisle; Dr. Wood, Dr. Fairless, Bothwell; Dr. Tuke, Fife District Asylum (Hon. Secretary for Scotland); Dr. Sanderson, Musselburgh; Dr. Jamieson, Royal Asylum, Aberdeen; Dr. Sibbald, Argyle District Asylum; Dr. Lowe, Bulgreen; Dr. Bruce Thomson; and Dr. Smith, V.-P.R.C.P.

The Chairman stated that the meeting was called in accordance with the fundamental rules of the Association, for the promotion of social intercourse among members. It had been proposed by several of the members that quarterly meetings should be held in the North, for scientific discussion and social intercourse, similar to those held in London. Dr. Bruce Thomson moved, and Dr. Sanderson seconded:—

"That the members present resolve to hold special meetings for the more efficient advancement of the objects of the Association of those resident in Scotland and the north of England, and all others who choose to attend."

Dr. Clouston moved as an amendment, seconded by Dr. Sibbald:—

"That the present rule of the Medico-Psychological Association providing for the holding of quarterly meetings in London is thought by the present meeting to be unsuitable, and that it should be altered so as to provide for two of the above meetings being held in Scotland or the north of England."

Both motions were adopted, Dr. Clouston's being submitted as a substantive motion.

The Chairman then brought the subject of clinical instruction in nervous and mental diseases before the meeting. After some discussion the following motion was agreed to:—

"That this meeting desires to express its strong opinion of the necessity of making the clinical teaching of insanity imperative in every medical curriculum, and requests the secretary to send a copy of this resolution to the General Medical Council, the Medical Faculties, the Examining Boards of the Scotch Universities, and the University Court."

It was also resolved that in the opinion of the meeting clinical instruction in mental diseases should be made a department of examination.

After the reading of some interesting papers by Drs. Tuke, Clouston, Bruce, Thomson, and Howden, the meeting separated.

UNIVERSITY OF ST. ANDREWS.

MEETING OF GENERAL COUNCIL.

AT the half-yearly meeting of the General Council of the University of St. Andrews, Principal Tulloch reported that he had received a certificate of the state of the poll in the election of the assessor to represent the General Council at the University Court, and that the certificate stated that Dr. B. Ward Richardson had been elected by a majority of 68, the votes recorded for him being 514, and for Dr. Cleghorn 446.

AT a meeting of the Royal Medical Society, Edinburgh, held on Friday last, the following gentlemen were elected Presidents for this year:—Alexander Bennett, M.B. and C.M. Edin.; David Page, Esq.; Charles E. Underhill, B.A. Catab.; John W. Fleming, Esq.

UNIVERSITY OF EDINBURGH.—We understand that the attendance this session at the University in the Faculties of Arts, Medicine, and Law is larger than it has been at this period of the session for about forty years. Up to Saturday week last, 675 students have matriculated in the Faculty of Arts, 470 in the Faculty of Medicine, 319 in the Faculty of Law, and 56 in the Faculty of Divinity—in all, 1,520. Besides these, 76 students matriculated last summer session. The matriculation is still going on.

The University of Edinburgh, on the 19th ult., conferred the degree of Bachelor of Medicine and Master in Surgery on Mr. Arthur Perigal, jun., Edinburgh.

THE ROYAL INFIRMARY—BALANTINE AND OTHERS v. THE MANAGERS OF THE MERCHANT COMPANY.—We are glad to have reason to believe that this action is on the eve of being withdrawn by the complainers, who have thus wisely followed the advice given at the recent meeting, and departed from their opposition to what is now so evidently the wish of the great majority of the subscribers.

LORD RECTORSHIP OF ABERDEEN UNIVERSITY.—Of the various noblemen and gentlemen whose names have been mentioned for the office of Lord Rector of the above University, vacant this month, Mr. Grant Duff, M.P., presently Lord Rector, and Sir William Stirling-Maxwell, Bart., of Keir, are the most popular among the students and others interested in the welfare of the Northern University. In all probability Sir W. Stirling-Maxwell will be unopposed, as Mr. Grant Duff has intimated his intention of not again becoming a candidate for the office, and, as is seen from the following passage from his letter, supports Sir William's claims:—"Sir William Stirling-Maxwell, whose name I see in the *Scotsman* as that of a probable candidate, although a Conservative in politics, is, to the best of my knowledge and belief, in all matters that most earnestly concern the interests of learning, a Liberal of the Liberals. If political issues were involved it might be my duty not to shrink from the contest; but I should be injuring the University of Aberdeen, as well as doing violence to my own feelings, if I attempted to stand in the way of its obtaining the services in a non-political capacity of a man with whom, except as a politician, I should be sorry to provoke a comparison, and who has already as Lord Rector of St. Andrew's, nor in that position only, shown that he can speak boldly, as well as think wisely."

ORIGIN OF SYPHILIS.

ACCORDING to the latest researches of M. Auzias Turenne, the birth-place of syphilis would seem to be America. He brings forward the following proofs:—

No doubt the disease became first recognized in Europe at the siege of Naples, 1495, the Italians and Spaniards being the defenders. Marcel de Cumes, the first syphilographer, says nothing of the contagious properties of the disease, but traces it from the sexual organs to the formation of pustules over the body.

Fracaster follows in this idea.

Four principal questions arise for consideration:—

1. Was the syphilis of Naples an epidemic of glanders?
2. Was it a rekindling or mixture of ancient and known diseases?
3. Did it arise spontaneously in Italy?
4. Was it imported from America?

The objection to the first is, that the glanders was described in the fourth and seventh centuries, and that it does not attack mankind so much as syphilis; that it attacks also more surely, more severely, and promptly.

The second idea, which Cullerier and Lagneau, senior, chiefly support, is, that the symptoms are to be found described amongst ancient authors, but without any connexion with the

original sore. The objection to this is, that notably the symptoms referred to by them were those of tubercular lepra, while the relation of symptoms to the first sore, supposed to have been so difficult of recognition, did not escape the observation of the ignorant American savages.

Did it arise spontaneously? This view is taken up by Fracaster, Marcel, Sanchez, and by many Germans.

In support of the proposition, it may be said that wherever syphilis is newly imported it soon acquires the intensity and violence of the epidemic of the fifteenth century.

That nothing of the same kind took place in America, but that it existed there before the Conquest.

The march of the disease can be chronologically traced from the West Indies across Spain, and finally to Italy, thence to France, and so through the world at large. All the names of the disease and of the after symptoms are to be found in the Carribean and Indian vocabulary. The Spaniards called it the "Indian disease."

The general conclusion points to the importation of syphilis from America.

SUBCOTYLOID LUXATION OF THE RIGHT THIGH IN A CHILD EIGHT YEARS OLD; FORCIBLE REDUCTION AND CURE.

A case of this kind is recorded in the *Gazette Médicale de Paris*, where the child was able, a few minutes after the occurring of the accident, to make its way home walking. The dislocation was treated as old rheumatism during a month; but, finally, not improving, the child was brought to M. Sistach, who found all the signs of a subcotyloid luxation: the inguinal fold being lost; the head of the femur could be felt on the upper and anterior part of the thigh; the femoral artery pulsating on its inner side; and there was some lengthening of the limb. Though the luxation had existed seventy-seven days, powerful and gradual extension and counter-extension was made, the child being chloroformed, and the leg bent on the thigh, and the thigh on the pelvis; gradually a feel of rupture ("craquement") of some of the adhesions was felt, and the head of the bone receded into its place, all the previous signs of lengthening and difficulty of motion disappearing, the fold of the groin becoming again marked, and the head of the femur was no longer distinguishable.

DISLOCATION OF THE FEMUR ON THE DORSUM OF THE ILIUM OF A FEW HOURS' DURATION, REDUCED BY FLEXION AND ROTATION OUTWARDS.

A case is recorded in the *Gazette Médicale de Paris* of a patient who was crushed by the falling in of a bank of earth. All the signs of dislocation were evident: shortening of the limb; approximation of the trochanter to the iliac spine; the foot turned inwards, resting on the inner ankle of the opposite foot, &c.

Chloroform was fully administered, and the leg being bent well on the thigh, the thigh on the pelvis, and the limb well rotated outwards, reduction was easily accomplished. In three months after he was able to work without the least inconvenience.

OVARIOTOMY PERFORMED TWICE ON THE SAME PATIENT; BOTH OVARIES REMOVED.

M. Boinet presented, at the Parisian Academy-meeting, a woman, aged forty-eight, on whom he had performed ovariectomy twice, with success after ten months' interval. First he had removed the left ovary, which weighed 17 to 18 kilos; and then, after ten months, the right ovary also, weighing 9 kilos. She very nearly succumbed to the second operation, owing to a diphtheritic angina.

WEDNESDAY, DECEMBER 1, 1869.

ST. BARTHOLOMEW'S HOSPITAL EXPLANATION.

THE Prince of Wales in the chair, Mr. Cooper White, Treasurer to this important charity, has, in a two hours' speech, attempted to refute all the charges made by some of the outside public against the management of the Hospital. Mr. White, it seems, has been Treasurer to the Hospital for the last fifteen years, and he proceeds to give an account of his stewardship during this period of office. Firstly, with regard to the treatment of the in-patients, Mr. White observes that the expenditure per head on this class of patients exceeds that in any other hospital in London. Everybody who comes for medical advice to St. Bartholomew's Hospital, he says, is properly attended to, and none are sent empty away. In 1861 a new Surgery was erected, at the expense of £7,000. The reception room for the patients was 36 feet high and 94 feet by 32 feet wide. Other institutions do not open their doors so wide as St. Bartholomew's, but require Governors' letters, or limit the number of patients seen. In 1868 the staff of medical men was increased from one to four. There was nothing that had not been done to make the nurses comfortable. Every one of them had her own bed; on an average, each nurse had 700 cubic feet of space in her room. It had been asserted that the London Hospital had cost in 1868 £29,000, and that £33,000 should have sufficed for St. Bartholomew's, instead of £60,000: but there were £10,000 spent yearly at St. Bartholomew's for diet alone. There were 431 beds in the London, and 553 at St. Bartholomew's; so that if the cost of the former was £29,000, the cost of the latter should be £37,000. The death rate of the nurses was not excessive. The obstetric department was admirably attended to. He himself was an unpaid servant. Finally he put in a document signed by the medical staff of the Hospital—Drs. Farre, Black, Harris, Andrew, Greenhalgh, Southey,

Church, Gee and Duckworth, and Messrs. Paget, Coote, Holden, Savory, Callender, Smith, Willett, Langton, and Coleman, testifying to the great improvements which have recently been made in the Hospital. The enlargement of the Surgery, the arrangement of departments for dental surgery and vaccination, of an ophthalmic department, of departments for the treatment of deformities and of diseases of the skin and ear, the enlargement of the wards for female diseases, and the conversion of the Hospital square into a place for open air exercise for the patients; the improvement of the museum, library, and chemical laboratory, making this Hospital one of the finest medical schools in this country. The medical men recommend the erection of special buildings for ophthalmic purposes, but are not in favour of any further specialities than those of the eye and of diseases of women. They look forward to the establishment of a Convalescent Hospital. They believe, that, by classifying the patients, the present staff of the Hospital will be found quite sufficient for all the work required to be performed. It appears that the applicants for out-patients far exceed in number those of any similar institution in London.

Such is the explanation offered by the Treasurer of this important medical charity, in refutation of the charges which have been brought against the management of the Hospital. And yet we hear from old Bartholomew's men that a great many changes are required to make their Hospital what it ought to be. In the first place, they complain that in many other hospitals, such as at King's College, University College, and also, we believe, at Guy's Hospital, the dresserships are competed for and given to the most distinguished and hard-working students, whilst at Bartholomew's a dressership costs £18 and a position as house-surgeon costs £50, half of which sum, however, is returned. We have no hesitation in saying that this is a most exceedingly bad plan, and doubtless it will soon be done away with. The gentleman who mentioned it to us observed that it had a tendency to get gentlemen as dressers; but we believe the day is now supposed to be gone by when stupidity combined with ready cash was considered as the only requisite for the title of gentleman. Then, too, this being the case, it is clear that the higher posts of physician, surgeon, &c., are more likely to be filled up from the richer men attending the Hospital, because these men have, of course, served in positions which render them more likely to be elected. This narrowing of competition is, of course, likely to be very prejudicial to the interests of science and to the end of the charity—the securing of the most able medical advisers to the sick poor of London. But, in addition to this, the Treasurer has been guilty of *ignoratio elenchii* in his replies in many cases. He is told that many of the nurses are miserably lodged and overworked, and he replies merely that, *on an average*, each nurse has 700 cubic feet. Now, if this is the case, many of them have probably far less than this cubic space. But the most serious charge against the Bartholomew's medical staff has been, of course, that they see far too many out-patients; and that it is a perfect farce to suppose that they can give any adequate attention to the host of cases which pass so rapidly before their eyes. In the first place, the error seems to be that there are too few officers for the out-patients. Probably, no one medical man should see more than 100 patients per diem. If he does, his attention will, in all probability, flag. The best remedy for this state of

things would be either to have a larger staff, or to do, as is done now at the Metropolitan Free Hospital and other institutions, limit the number of new patients seen daily. At the last mentioned Hospital about 100 new cases are seen daily by three medical men; two physicians, and a surgeon. If only 150 or 200 new cases were daily admitted as out-patients to St. Bartholomew's, it would cause the scandal to cease to a great extent. But, the fact is, wider changes than any of these we have adverted to are required. In all probability, ere many years have passed over our heads, the Hospitals of the Metropolis will be brought under some central Board of management, and then we may hope to see a better system of appointments to the public function of medical adviser to the poor, instead of the present crude method, which excites so much distrust, and performs its duties in such a bungling manner.

DRAINAGE AND SEWERAGE.

THE letter of Mr. Bailey Denton, in the *Times* of Nov. 18th, on Sanitary Works, deals with facts that are becoming daily of increasing consequence, and that are well worthy the attention of all those who may think the prevention of disease to be better than cure.

Mr. Denton insists on the importance of keeping the sewage in sewers quite separate from the subsoil water if we wish to prevent the earth from becoming sewage-sodden and water supply thereby poisoned. This question, it must be remembered, is a distinct one from that bearing on the disposal of the surface and storm waters in channels separate from those which convey the sewage of dwellings, after the plan recommended by Colonel Ewart and Mr. Menzies; what Mr. Denton deals with is the water of the subsoil, which, he maintains, should be carried off in deep under-drains, while the sewage is kept strictly within the sewer.

In many towns of which the drainage, or rather sewerage, has lately been improved with great apparent good to the health of the community, the subsoil water is carried off by the sewers. Thus, for example, at Salisbury, the floors of the discharging brick mains are laid without cement, for the purpose of admitting subsoil water. Now, if subsoil water can get into the sewer, it seems pretty certain that sewage can get out into the subsoil, and thus the earth becomes "excrement sodden," and it will be a matter of future sanitary interest to observe and see if evil effects actually arise attributable to this arrangement.

At Bedford, as at Salisbury, the sewers take off the subsoil drainage, and the ordinary discharge from the sewers is about three times as much as the water consumed in the town.

It is satisfactory to observe, from the statistics collected by Dr. Buchanan, how the death rate of towns especially the death rate from phthisis, has been lowered by this thorough drainage of the subsoil; but the very same report that contains the results of Dr. Buchanan's researches in this matter contains also reports of serious outbreaks of fever in certain towns and villages unmistakably due to poisoning of the water supply by sewage.

The danger would be effectually guarded against if Mr. Denton's plan could be carried out of having deep drains for the subsoil water and tight sewers for the town sewage.

Arrangements might be made for admitting the subsoil water into the sewers at certain points for the purpose of flushing, and such a plan of drainage and sewerage seems to us as perfect and as safe as it is possible to be.

The remarks of Mr. Denton on the sewer arrangements of seaboard towns are instructive and serve to explain the startling outbreaks of epidemic disease, which at times are met with in these places. Imagine large iron pipes, running straight out into the sea, and carrying away the refuse of the town; at low water, probably, the mouth of the tube is exposed so that the wind can drive strongly up it, while at high water the sea rises up to the tube, and both states of course force the sewer gases back up the drains into the houses with a power that few stink-traps and syphons are likely to withstand. Further, too, it appears that the various properties of sewer gases are increased by the admixture of sea-water, but on these matters we are promised more definite information presently through the agency of the Sewage Committee of the British Association and Dr. Paul. It is to be hoped that some of the English watering places, of which unsavoury rumours are now and then current, will by degrees learn to follow the example of the people of Hastings, and instead of running their sewers straight out into the sea immediately under people's noses, will carry them to large remote tanks or receptacles which can be opened and discharged on the ebb or flood tide according to whichever will convey the discharged matter the greatest distance out into the sea.

Notes on Current Topics.

Purchase of Hospital Appointments.

IT appears that in July last there was some uproar in St. Bartholomew's Hospital because of an order issued by Mr. White, to the effect that, neither house-surgeons nor dressers were to be allowed the right of prescribing quinine or several other expensive drugs for the patients. The house-surgeons and dressers pleaded that they had purchased their offices, it seems, under the understanding that they were to enjoy the customary privilege of prescribing. We cannot help thinking that it is a very great blot on the fair fame of St. Bartholomew's Hospital, that it still keeps up the system of selling the offices of house-surgeon and dressers, &c., instead of allowing these offices to be the rewards of merit, and granting them to those students who pass the best examinations. Surely the best man is required for all posts when the poor are to be served.

Sir Patrick Dun's Hospital and the Monopoly of Hospital Education in Dublin.

THE observations which we have made from time to time on this matter will, doubtless, have made our readers familiar with the circumstances. The last stage at which the movement for the removal of the restriction on candidates for medical degrees in the University of Dublin had arrived was the reply of the Board of Trinity College to the effect that they would be ready to remove the protective regulations as soon as Sir Patrick Dun's shall be in the position of receiving the undivided services of its medical staff. As we explained at the time, this phrase

means as soon as plurality in hospital appointments shall have ceased. It will, no doubt, have occurred to our readers that a fault in the arrangements of the hospital is a strange reason for refusing an act of justice both to students and to the teachers of Dublin. It might naturally be supposed that if an anomaly injurious to the hospital exists, the Board of Trinity College can and ought to deal with it, and that to maintain an unfair and objectionable monopoly, on the plea that certain alleged abuses exist, is a very great aggravation of the offence.

Since the resolution was arrived at, a change has taken place in the staff of the hospital, and one of the difficulties which impeded the action of the Board has disappeared. We learn that the Committee of the Physicians and Surgeons of Clinical Hospitals in Dublin have seized the occasion again to press their views upon the Board. They have accordingly addressed to them, through their Hon. Sec., the following letter:—

“November 13, 1869.

“DEAR SIR,—I am requested by the Committee of Physicians and Surgeons of Clinical Hospitals in Dublin to request that you will have the goodness to bring under the notice of the Board of Trinity College the memorial submitted to them in March last, and their resolution referring thereto passed on the 24th of April.

“The Committee have learned that, since its adoption, a vacancy in the medical staff of Sir Patrick Dun’s Hospital has been filled by the appointment of a gentleman whose undivided services are at the disposal of the institution.

“The Committee feel that it is very undesirable that the injustice complained of by the memorialists should be indefinitely perpetuated, and they trust that the Board will see fit to make an immediate order for the abrogation of the regulation which renders obligatory the attendance at Sir P. Dun’s of candidates for the medical degrees of the University.

“Awaiting the favour of your reply,

“I am, Sir, yours faithfully,

“A. H. JACOB, Hon. Sec.”

Lunatics, Idiots, and Cretins in France.

A SPLENDID volume, issued from the Statistical Department of France, gives for 1866 the results of investigation into the psychological condition of the country. The lunatics number 50,726, or 133 for each 100,000 inhabitants. Of this number 63 per cent. are treated in asylums. The proportion of the sexes is 91 men to 100 women. In the department of the Seine, however, the ratio rises from 133 to 239 in Seine and Oise to 299.

Idiots and cretins count 39,953, or 105 per 100,000 inhabitants. The proportion of the sexes is inverse to that of lunatics, 132 men suffering from these forms of lunacy to 100 women. Almost the whole of this class remain with their families, not more than 1,500 being confined in asylums.

The proportion of 105 per 100,000 increases in Savoy to 383, and in the Alps to 262. Taken together, the lunatics, idiots, and cretins number 92,000, or 1 in 420 of the population. No less than 50,000 persons suffer from goitre, of which 7,500 are cretins, and the proportion amounts to 27 per 1,000 in Savoy.

Doctoresses in America.

THE “go-ahead” tastes of Brother Jonathan do not appear to secure for female doctoresses a more gracious

reception in America than amongst ourselves. At the other side of the Atlantic the movement would appear to be much more universal than with us. The *Philadelphia Public Ledger* says:—

“On Saturday last, for the first time in the history of the Pennsylvania Hospital, a large class of female students attended the valuable clinical lectures at that institution. There were twenty-seven of them present at the Hospital Clinic on Saturday morning attending the lectures of Drs. Da Costa and Hunt. This fact is noteworthy as an interesting event in the history of our Philadelphia medical schools; but, in addition to that, there is a necessity for comment on the occurrences after the lectures were over, and the classes were dismissed. Between two and three hundred male students, by a concerted plan, and in spite of the efforts of the managers of the hospital to preserve order, ranged themselves so as to occupy both sides of the whole of the foot-walks inside of the hospital enclosure, which compelled the twenty-seven lady students to take the cart-way, and thus pass between the double lines of the male students, whilst the latter saluted them with taunts and jeers, mock applause, and real hisses. Comment upon such unmanly proceedings can only take one course, and that is unqualified censure.”

Meat Preserving.

A MELBOURNE paper says that the satisfactory intelligence received by the last few mails, respecting the disappearance of the prejudice once existing against Australian preserved meat as an article of food, has not only led to the formation of several new companies, but has encouraged manufacturers at present in the field to extend their operations. A company recommenced operations in June last, since when they have shipped 300 tons of meat in tins, and the whole has met with a ready sale.

The Dublin Pathological Society.

THE opening meeting of this Society took place last Saturday, and the Council for the ensuing year was then elected.

We notice the fact with the view of calling attention to the constitution of that Council, and to the perpetuation of a principle of exclusiveness which we regret to see manifested in a professional association for the advancement of our art.

Analysis of the list of gentlemen elected yields the following conclusions:—Out of nineteen members of Council, no less than nine are chosen from the medical staff of one individual hospital, three from another, and only seven from all the other medical institutions of Dublin. Three principal hospitals have but one representative each, and three have none at all. The obvious effect of so peculiar an apportionment of the honours of the Society must be to convert it into an arena for the exhibition of morbid specimens almost from one out of all the hospitals of Dublin, and, therefore, to narrow the interest which should attach to its proceedings.

This anomaly is paralleled by the financial arrangements of the Society, which would seem, from their yearly uniformity, to have become part of the institution. The communications to the Society being made *vis à voce*, it has been essential to employ a short-hand writer for the purpose of recording its proceedings. It would reasonably be presumed that, so serious an expense being incurred, the contributors to the proceedings of the Society should have the benefit, and that a proof of th

report would be furnished to any Journal disposed to give it publicity. No such course is pursued. The communications to the Society are decently interred in a pamphlet of Transactions each year, and furnished to the members of the Society about a year after even the name of the contributor or the nature of his contribution has been forgotten.

The proof-sheets of this pamphlet are supplied to the *Quarterly Journal of Medical Science*, and published in its pages long after interest in their contents has passed away, yet long in anticipation of the Transactions. Thus the greatest proportion of the funds of the Society is expended in reproducing *verbatim et literatim* the matter which has been for months on the shelves of every one who takes a quarterly journal, and, we will add, in carefully concealing the proceedings of the Society from the Profession at large.

If the contributors who undertake the labour of working out elaborate pathological investigations are satisfied to restrict the result of their labours to an audience of say one hundred, we can only say that their feelings differ from those of the members of every professional society in existence.

University of Edinburgh.

THE University Court met on Thursday. Parties were heard on the matter of a memorial of the Royal College of Surgeons as to the system of teaching clinical surgery in the University. - The Court approved of the admission of women, not studying medicine professionally, to the whole of the course of lectures on chemistry to be delivered by Prof. Brown to women studying medicine. The Court sanctioned a special arrangement regarding fees for women attending the class of physiology as medical students, and approved of the admission of women, not studying medicine professionally, to certain parts of the course of lectures on physiology to be delivered by Professor Bennet to women studying medicine, the fee for such part of the course to be £2 2s.

The Elysium of Quackery.

THE *Californian Gazette* publishes the following analysis of the Profession in Boston :-

"The Boston Directory for 1869, which has just been issued, contains the names of 303 physicians, members of the Massachusetts Medical Society; 40 members of the Massachusetts Homœopathic Medical Society; 11 members of the Massachusetts Eclectic Medical Society; 70 who attire themselves in female garments; and 200 'other physicians.' One of this latter class delights himself in the title of 'analytic physician;' another practises 'nature-pathy;' another goes it upon the 'equalizing' principle—this may be supposed to refer to pockets—another strengthens weak finances by the 'Swedish movement-cure,'—the word movement probably indicating frequent change of residence—another is a 'magnothist;' and still another is satisfied to proclaim his merits in good old English as a 'bone-setter.'"

The Prevention of Syphilis.

THE advocates for the extension of the Contagious Diseases Act to the civil population, as well as the sanitary reformers of the public services, have experienced great discouragement from the results of the working of the Act, as reported in the last Army Medical Report. The

diminution in the number of cases of syphilis appears to be almost insensible, despite all the precautions provided by the Act. The admissions into hospital from venereal disease at all the various home stations during the year 1867 were no less than 21,399 out of a force of 73,420, forming just about a third of the admissions for all complaints in the same time, which amounted to 63,904, the average constantly sick from venereal complaints being no less than 1,258. This average has been greater in 1867 than in the preceding year at all the large stations except Warley, where the proportion in the two years was identical, Canterbury, Winchester, Devonport and Plymouth, and Shorncliffe, where there was a very slight reduction, and Chatham and Sheerness, where the ratio of admissions in 1867 was 49 per 1,000 of the strength lower than in the preceding year. The increase was most marked at Manchester, Preston, Dover, the Isle of Wight, Edinburgh, and Limerick. The Contagious Diseases Act of 1866 was in operation during the whole year at Devonport and Plymouth, Portsmouth and Gosport, Chatham and Sheerness, and Woolwich, and for eight months and a half at Aldershot; but the results do not seem as yet to have realized the expectations which were entertained of its effects in reducing the amount of these diseases among the troops, except at Chatham and Sheerness.

RATIO PER 1,000 OF MEAN STRENGTH.

	1867	1866
Manchester	510	312
Colchester	500	451
Portsmouth and Gosport	378	359
Canterbury	375	379
Preston	361	272
Dover	354	248
Dublin	333	323
Warley	328	328
Isle of Wight	327	254
Devonport and Plymouth	312	317

"Quietness" again.

A CASE of poisoning by "Mrs. Winslow's Soothing Syrup" is reported in the last issue of the *Californian Medical Gazette*. The victim, an infant six months old, had taken no medicine except this Soothing Syrup, of which it had taken, within ten hours, two doses of about one teaspoonful each. The writer had the syrup from which these doses were given analysed. There were 10 drachms of Soothing Syrup in the vial, and it yielded of morphine and other opium alkaloids 1 14-100 grains, very nearly one grain to the ounce of syrup. The printed directions for administering the medicine are as follows: "For a child under one month, 6 to 10 drops; three months old, half a teaspoonful; six months old and upwards, one teaspoonful three to four times a day until free from pain. In dysentery, repeat the above dose

every two hours, until the character of the discharge is changed for the better." Here we have a dose of morphine equal to 10 drops of laudanum given to a child of three months old every two hours, and double the quantity to a child of six months old!

A Cholera Charnel House.

THE City of Umritsur has, as our readers are aware, been almost decimated with cholera this year; and with the view of providing against its recurrence, an investigation into its sanitary condition has been made by Assistant-Surgeon Taylor, the results of which appear in the *Indian Medical Gazette*. Dr. Taylor says:—

During the prevalence of cholera I have gone into all the narrow, out-of-the-way streets and lanes, and have thus had an opportunity of ascertaining their sanitary condition, which I have no hesitation in stating is so defective, that the present outbreak of disease may be fairly ascribed to it, and which, unless rectified, may be dreaded as a constant source of epidemic sickness in future, or which may even convert disease now epidemic and occasional into disease endemic and persistent.

The chief points to which I want to bring attention are:—

1st.—The two old underground sewers. Cholera has been more severe in the vicinity of these sewers than in any other part of the city.

2nd.—The habit of placing at the sides of drains, in the streets, the filth scraped from the surface drains, instead of removing it at once, is highly dangerous.

3rd.—The ordure from the houses is all day long lying unremoved in the narrow gullies.

4th.—The kutchra drains in the lanes and koonchas seem never to be clean. Black, putrid, fermenting semi-fluid matter, consisting of human ordure mixed with all manner of filth and refuse, constitute the contents of these gutters, and their condition, stagnant from the nature of the ground, seems never to be changed by any attempt at cleaning them.

5th.—A condition hardly remediable, I fear, is the state of the hovels dwelt in by the poor, the floor often four to six feet below the ground round them—that ground being below the surface of the streets and levels of the drains; without attempt at ventilation, filthy beyond belief from the accumulation of fluid refuse, and miserably inadequate in cubic space to the accommodation of the numbers living in them: they are perfect as hot-beds of disease, especially of cholera or more fatal fevers.

6th.—The people are in the habit of washing round the wells, and of throwing water about when drawing it; cattle brought to drink void urine and dung on the spot.

Umritsur is a city of over 150,000 inhabitants, and in the month of August, 2,364 died from cholera.

Transfusion of Blood in Traumatic Fever.

PROF. HUETER has lately used transfusion, though without success in some cases, certainly with a temporary benefit in others.

In the first case, a brazier got a burn on the body; intense fever came on, and in eight days the patient was in extreme danger. Transfusion was now practised. Suppuration commenced the next day, and the dead parts separated. A second time transfusion was performed. Several

papillæ now formed at the wound. On the twenty-first day hæmorrhage ensued from these. The next day, when the patient was *in extremis*, transfusion was again used, but death took place during the operation.

The second was a case of suppuration at the hip-joint, with a huge suppurating sac at the knee-joint. Resection was performed, and the patient, worn out with consecutive hæmorrhage, fell into deep collapse. Transfusion was now performed, twelve hours after the operation. The condition of the patient and aspect of the wound improved. In three weeks afterwards the patient died of pneumonia, and *post-mortem* examination showed extensive grey hepatisation at the bases of both lungs.

The quantity of blood injected varied from 8 oz. to 1 lb. Before the operation was completed the patient, though delirious up to this, recovered consciousness, answering questions, &c., and the pinching of the features disappeared. In about half an hour afterwards a severe rigor came on, and fever became established.

Prof. Hueter has performed the operation five times on three occasions from the radial, and twice from the posterior tibial artery.

Lady Students at Edinburgh.

IT appears from one of our correspondents, that the lecturers who now are engaged in their tuition as medical students, are Dr. Crum Brown, who teaches Chemistry from 11.30 to 12.30; Professor Hughes Bennett, who lectures on Physiology, from 12.30 to 1.30; and Dr. Millar, who lectures on Anatomy, from four to five daily, except Saturdays. Practical Dissection is to be undertaken by the fair students on the 1st December, and is to be carried on in a room in Minto House, where Dr. Millar gives his lectures. Dr. Millar lectures to his small class of five students in a small lecture theatre, which is said to be far too large as yet for the small class. Probably next year the class will be very much larger than it is at present. It appears, however, that there is some difficulty still in making the course of Anatomy qualify, since Dr. Millar has not as yet been able to obtain the consent of the College of Surgeons of Edinburgh; and we believe that this is necessary. Our surgical friends are in general rather more against the lady movement, than our medical friends! No clinical instruction has yet been provided for the lady students; but they assure us that they are in hopes of *creeping* into some Dispensary or Hospital ere long.

St. Pancras Infirmary Inquests.

VERDICTS, it appears, of death accelerated by overcrowding and want of ventilation have been returned by recent juries sitting on cases of death in this Infirmary. Dr. Ellis deposed concerning a female patient of the name of Jane Hayes, aged seventeen, that when she died there were 29 patients in the ward, and that the quantity of air per patient was 600 cubic feet, which was 250 less than the minimum requirement of the Poor Law Board. He thought that the air of the ward had accelerated the death of this patient. He thought there should only be 144 patients in the ward, but of late there has been as many as 203. Mr. Corbett, one of the Poor Law Inspectors, said that since 1866 the wards of St. Pancras Infirmary had always been more or less overcrowded; and he stated that the reason why the rule as to each patient having 850 cubic feet of

space was not enforced was, because it was thought that many patients whose cases were urgent might be thus excluded. Dr. Brydges also thought there were too many patients in the wards; but seemed to say that it was not in the power of the Poor Law Board to do more than remonstrate, although he afterwards admitted that the Board had power to limit the number of patients taken into the Infirmary. Mr. B. Carter, of the *Lancet*, said he did not know of any Hospital in London where there was so much overcrowding or so great a want of ventilation as in St. Pancras Infirmary. He considered the wards as quite unfit for human habitation. The Coroner truly remarked that it seemed to him no one was criminally responsible for the state of the wards. The verdict come to by the Jury was, we think quite correct: "They regret that the Poor Law Board have not enforced the sanitary measures which they have from time to time recommended to be carried out." St. Pancras Workhouse, it seems, is nearly the largest in the Metropolis, containing 1,600 inhabitants.

The Late Dr. Locking.

We regret to state that on the 20th ult. this gentleman died very suddenly, at 9 a.m. in bed. He had only been left by his wife a few moments in his usual health. He had suffered for some time from heart disease, but did not pay much attention to it. On the previous evening (Friday) he was with a patient, and seemed tolerably well, except that he said he felt rather weak. He held the appointment of Physician to the British Lying-in Hospital.

The Prescription Copyist.

MESSRS. LETTS, the publishers of the diaries and pocket books, and of whose Medical Diaries and Medical Account Books we have often spoken well, have brought out a novelty for which we predict success, as it supplies a want often felt by busy consulting men. By an adaptation of the manifold writer to the purpose, they enable any physician or surgeon to keep a copy or duplicate of the prescription he gives a patient without the trouble of copying it. He retains it in a neat book, which may be carried in the pocket or lie on the desk—furnished with pencil and everything complete. The prescription is easily separated for the patient, as the sheets of paper are perforated. We mean to use the new copyist regularly. One of a larger size would be as well for the consulting-room table, and the small 8vo. for the pocket.

Royal College of Physicians of London.

The Lumbian Lectures will be delivered by Dr. Risdon Bennett. Dr. Sibson will deliver the Croonian Lectures, and has selected the subject of Aneurisms. The Gulstonian Lectures, which according to the foundation must be given by one of the four junior Fellows of the College, have been confided to Dr. Maudsley, who will, no doubt, take up some subject in connection with Insanity. The Harveian oration is to be by Dr. Gull.

We have several times lately commended the liberality of this College, and rejoiced at its courage in establishing a single qualification. We hope that nothing will induce the College to swerve from the path on which it has entered. It may thus secure the one faculty-system and hold its own rank as the first medical corporation.

A fresh concession was proposed at the late meeting of Fellows, and agreed to—viz., to allow the *Licentiates* to use the *Members'* reading-room, and to permit *Members* the privilege of access to the *Fellows'* reading-room, with the right of taking books out.

We don't think *Licentiates* will care much about it, but we know some *Members* who have often said that the *Fellows* might let them use the library. The *Members* feel that at present they have no status in the College. They are pure physicians, while the *Licentiates* may be general practitioners, and yet the latter are disposed to call themselves physicians. The middle grade of Member is neither "fish, flesh, nor fowl," and the encroachments of the lower grade threaten to destroy it. The remedy seems to be to enlarge the body of *Fellows*, so as to make promotion to that grade more rapid.

The Profession as a Trade.

WITH reference to our remarks in the *Medical Press and Circular* of the 10th ult. we have received the following letter:—

"SIR,—As to Mr. J. Senior Turner having received a month's notice from the Board before his district is taken from him and conveyed over to me is simply untrue. The Guardians intend to make a new district, and the No. 5 district is to be divided. Mr. Turner's term of office having expired, he was asked to hold the same for two months longer, to allow the Clerk time to correspond with the Poor Law Board to obtain their sanction to the proposed alteration. It is also untrue that the Clerk read a letter from me stating that I had taken a house at South Normanton, and seeing such reported in the *Midland Gazette* I was naturally annoyed, and finding that my patients were under the impression that I was leaving (*sic*) and as this was doing me an injury, I maintain that it was my duty to contradict it in the way that I did. As regards 'the spicy production' which you say 'reflects no credit on my schoolmaster and the Profession,' I beg to state that neither are at fault, the editor of the above named paper having not only altered the wording of my letter, but even the initials of my name.

"I do not deny that I have applied for the appointment, and why should I not? The Clerk having told me that it was vacant, and also that it will be advertised immediately matters are settled with the Poor Law Board.

"I cannot see that 'the Profession' will blame me in any single respect when they hear the facts of the case.

"In conclusion, Sir, I hope that 'the competent local authority' will in future confine himself to the truth, which in this case he has not done.

"I am, Sir,

Your obedient servant,

H. W. DIVER, M.R.C.S. Eng.,
L.R.C.P. Edin. &c.

"Nov. 24th, 1869."

Opinions of the Journals on Mr. Foster White's Speech.

THE *Lancet* says the Governors will be grievously deceived if they think the public and the Profession will accept their verdict. The *Daily News* says the jury was composed of the very persons whose usefulness was called in question, and therefore its decision is valueless. The *Times* demands a public inquiry into the question. The *Echo* says the majority of the charges are not answered at all. The *British Medical Journal* says, of Mr. White's statements, that, on the whole, it is satisfactory, but with some considerable drawbacks.

Hospital for Women in Soho-square.

ONE of our contemporaries, in an article concerning the above charity, mentions that the bulk of general practitioners regard hospitals as little better than implements of robbery, since their respectable patients are often taken in and treated by the best physicians and surgeons entirely gratis. It appears that the "Hospital for Ladies" in Harley-street receives ladies into it who pay a small fee; but the medical men in this case, as in that of the Soho-square Hospital, remain without any payment. Is not this all very foolish? Why *not* pay the doctor?

A Hundred Patients per Hour.

MR. WHITE denies that patients at St. Bartholomew's are ever seen at the rate of one hundred per hour, but it seems, nevertheless, to be a fact. We hear thus of cases of primary sore being treated for three weeks with haustus ammoniac acetatis, and this being after this time found quite useless by the dresser of the day. Pleurisy with effusion, too, it is reported, in some cases is treated by a slight cough mixture, although the case is sent in by a former pupil of the hospital as a *serious case*. We are accustomed ourselves to see patients rather too quickly; but we have never been able to see more than 50 in an hour, even with the most rapid diagnosis. One hundred per hour requires an inspired observer, and we are not inspired.

Royal Sea-bathing Infirmary.

THE half-yearly General Court of the Governors of this institution, established at Margate in 1796, for the scrofulous poor of all England, was held on Friday last, at No. 1 Queen-street, Cheapside. The report shows that on January 1st, 1869, there were 135 patients in the hospital, since which time 563 have been admitted, making a total of 698. The number of out-patients was 115. Of this number 138 were discharged cured, 169 greatly benefited, 43 unrelieved, and nine died. 201 patients remain in the hospital.

Royal Hospital for Incurables.

THE late Marquis of Westminster has recently given a donation of £1,000 to this charity. The building itself is finished. The number of beneficiaires last year was 365—inmates, 119; pensioners, 246.

The Poor-Law Board Inspectors.

THE recent verdict at St. Pancras has done some service in saying that "the Poor-law Board have not enforced the sanitary measures which they have from time to time recommended to be carried out." It is really too bad that such a powerful body as the Board should be so neglectful of its duty as to allow the guardians of any parish to curtail the amount of cubic space allowed to each patient in its infirmary wards by no less than 250 cubic feet. Guardians of the Poor are, of course, only plain men, and if they are not forced to keep to some rule laid down by more skilled persons than themselves, they will be apt always to follow the dictates of their own uneducated judgment. It is most unfortunate, too, that our Poor-law Inspectors are men frequently entirely unsuited for the post.

Dr. Karr on Health and Disease, viewed in relation to the Opinions of Darwin (Malthus), with Illustrative Cases.

DR. KARR, the well-known contributor to the *Lancet*, and, we believe, physician to Mr. J. S. Mill, is to read a paper with the above heading at the West Kent Medico-Chirurgical Society, on December 10th, at 8 p.m., to which gentlemen interested are invited to come to Blackheath.

The Medical Teachers' Association.

THIS Association held its annual meeting on the 19th ult., Mr. De Morgan in the chair. Dr. Miller was elected president, Dr. Sibson, treasurer, and Messrs. Rivington and Henry Power, honorary secretaries. The subscription has not been found to cover expenses; it has, therefore, been raised from five to ten shillings. The Council appointed for the purpose of examining the question of clinical instruction of students, before being finally examined, reports:—

1. That each student should be required to act as dresser and clinical clerk, the time devoted to each being equal.
2. That each student shall attend 20 cases of midwifery.
3. That clinical examinations of the students be instituted from time to time, and that all examining bodies be urged to examine in this way all students coming up for examination.

Unqualified Medical Practitioners.

A WORKING man in St. Luke's loses a child, his wife having consulted a man of the name of Smith, who writes *surgeon* on his door. This "doctor" gave the child some powders, and then the mother called on the parish doctor, after which the child died. Dr. Pottle proved that the child died on Tuesday, of convulsions, and thought (how does he know this?) that if the child had been properly treated by a medical man, it might have recovered. The jury gave a verdict of "Death from convulsions."

Another case is mentioned where a mother took her child, aged 11 days, to a Mr. Wilson, Old street, St. Luke's, and he prescribed for it. The child died, and Mr. Wilson demanded two shillings for a certificate. Mr. Hayes, medical assistant to Mr. Wilson, said he had no right to give a certificate of death, but often did so. The Coroner made some very strong remarks on the conduct of the chemist's assistant, and the jury returned a verdict of "Death from natural causes."

Women Doctors.

A CORRESPONDENT in the *Lancet* objects greatly to women following the profession of medicine, and allowing that we want suitable employment for women, especially for the restless, strong-willed women amongst us, advises them to be off out of the country to foreign shores where their countrymen are pining and calling out for them. This reminds us of the advice we sometimes give to a troublesome patient—to try a "change of climate," *i.e.*, not to weary us any more.

Another correspondent writing from Paris tells us that a young woman, about some 25 years of age, is to be seen

dissecting in one of the pavilions of the Ecole Pratique. Several young men, it appears, were engaged in dissecting the same subject. The correspondent is very much "shocked," and repudiates the idea of this "young woman" being English, adding—she is said to be an *étrangère*—American, Prussian, or Scottish. Bravo! Mr. Correspondent.

MR. A. COOPER, F.R.C.S., has been elected Surgeon to the out-patients of the Lock Hospital.

THE mortality of London was no less than 31 in 1,000 last week.

WE are happy to state that the Princess of Wales and the little Princess are both doing well.

THE Archbishop of Canterbury, at the time of going to press, was in a slightly better state.

THE King of Italy has completely recovered from his dangerous attack.

THE rate of postage to France is to be reduced from 4d. to 3d. for one-third of an ounce.

IT appears, from a late decision of the Poor-Law Board, that Officers of Health have no jurisdiction within work-houses.

PROFESSOR BOECK, of Christiania, the well-known syphilographer, is at present visiting New York, and will probably remain some months.

DR. WALSH, of Clare-street, Dublin, has been elected Surgeon to Jervis-street Hospital by a large majority of the Governors.

ARE we never to have a change? We ask this on reading that Dr. John Storrar has been re-elected member for the University of London at the General Medical Council. Dr. A. Thompson also has been re-elected to represent Glasgow and St. Andrews.

RICORD has received from the Emperor a snuffbox worth 20,000 francs, and it is said that he also will be made Senator. His advancement to that dignity has been spoken of before, and was more than once reported—perhaps erroneously—to have been retarded by his intimacy with Prince Napoleon.

ROMAN FREEDOM.—The Roman Government, through the "Congregation of Health," has ordered all physicians under its jurisdiction instantly to cease their attendance upon patients dangerously ill, who decline to confess to a priest and receive the sacrament. Doctors refusing obedience to this order are threatened with excommunication and imprisonment. Does such a method of making "Catholics" commend itself to our Roman Catholic readers? It would appear that there is tyranny in other places than in Ireland, and other tyrants besides the British Government.—*Plain Words.*

Correspondence.

LARGE FAMILIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is highly necessary that there should be a full discussion of this question about "Over Population and Large Families," provided always that we clearly understand under what category it is to be classed. The religious aspect of it is not appropriate for the pages of a medical journal: therefore, any allusion to religion, whether *pro* or *con*, is impertinent. We must look at it here as a social question, comprising considerations partly of political economy, partly of mutual rights, partly of public health, and partly of physiology. Such being the case, and the whole subject being so important and so deep, and including so much relating to the mundane welfare of us all, it is no matter to be flippantly dealt with, or for every sciolist to utter words about; still less does it open either a fair field for sneers at religious faiths or for declamations in favour of them, nor yet an opportunity to cry up or to cry down particular writers, authorities, or persons. In the discussion there has been something too much of this. A better tone is wanting. The subject should be dealt with in thorough earnestness and straightforwardness. You, Sir, as editor, are the chairman of the discussion, who must fearlessly see that every person worth hearing is impartially heard, without undue preponderance of any one, and with authority to check any unfair or unparliamentary expressions. You have had some valuable and temperate communications; but the debate has been a little one-sided. We have been more than sufficiently urged to believe in great thinkers, and to follow the practices of the French. But the majority of your readers and supporters, Sir, are British—lovers of straightforwardness, uprightiness, endurance, hard work, and strong sense. We want no insinuations wrapped up in ambiguous phrases or foreign tongues. Whatever is to be spoken of in your pages, may be said in plain words. Let the discussion be carried on not for partisanship, but as by honest truthful men, boldly seeking for truth before all the world.

I have had little time, or wish, to take part in the question; but, having been urged to do so, will for once say a word. Many men, many minds. Even the greatest men cannot induce a whole community to adopt their views. Each class of persons will follow those doctrines which most conform to their desires, thoughts, and circumstances. This is the inevitable law of societies. And, in accordance with that law, not dogmatically trying to force people into my views by any form of words in my power (which no man has any right to do, and which never yet helped to discover anything), but for the acceptance of those who may approve, I put forward what I have to say; remembering, that the actual present posture of the question is, not that the truth has been discovered, and has only to be advocated and driven into people's minds, but that we are even now seeking and investigating to find it out.

The passage from childhood to puberty is not immediately followed by the best powers of perpetuating the species. A period of several years intervenes, during which, though sexual desire exists, there is not the greatest fruitfulness, and children produced are not the strongest. Moreover, during this period, in which both sexes are growing, and have not attained to their full strength, sexual indulgence is hurtful; and it is by vices acquired at this time that the bodies and minds of some of our young people are most terribly shattered. Such is the teaching of nature. It is, therefore, evident, that this period should be one of perfect restraint and chastity: when the mind should be called off from the suggestions of desire by a thorough intellectual training, when the muscular development of the body should be carefully fostered, when everything should be done to improve physical health, when employment should be as full as the powers justly admit of, and when the utmost care should be taken to cultivate moral purity.

Again, when health fails, whether from age or illness, it is found that although desire does not cease, indulgence hurts, nay, sometimes kills. Of the latter, every medical man must have seen instances. Hence it is clear that this also ought to be a time of restraint and chastity.

Then, finally, in the married life of one man and one woman (which appears to be the best and wholesomest state) there are constant occasions of abstinence. What with chance illnesses of

one party or the other, the fatigues and exigencies of daily work, perhaps absences, and always that mutual consideration for each other which forbids the indulgence of selfish desire to the other's detriment, also in the case of the woman, monthly periods, confinements, &c., and in that of the man, the physical impossibility of frequent repetition, there arises by instalments from each a degree of restraint which sums up into a very considerable amount. Moreover, in those instances in which matrimonial indulgence is too frequent, we invariably find that mischief results. Either the woman's constitution is shaken by frequent childbearing or miscarriage; or some uterine or other disease comes on: the man suffers no less, either in body or mind: and in both there is a tendency to premature old age, or to some form of illness, not seldom resulting in broken health or in a passage to the tomb. Thus even in married life restraint is the normal condition.

Such are the every-day readings of medical experience. So common are they, that I should scarcely have ventured to occupy your space with them, but that they seem likely to be overlooked. We see in them a constant series of restraints and checks: both in youth, in married life, and in failing health and in old age. This, then, is the teaching of nature:—No indulgence without its salutary counterpoise. The true law of nature in this, as in much else, is *moderation*. We have constantly to inculcate and to learn *self-control*; and it is to this that natural laws, read and understood in simple faith and honesty, bring us. I am not advocating this or that rule, or line of practice; but I point out the principle, as fairly and emphatically indicated by the natural conditions of our life; and I think its application to the question of over-population and large families, to be the only right solution of that problem. There is a little "Dialogue on Marriage" (published by Pitman, London, 1866), which might be read with profit. Individuals must apply this principle for themselves as they think most fitting. Some may think slightly of it. Others may agree with me in its paramount importance, and in its sovereign obligation on us all, but may differ from me as to practical applications. That must be so. For myself, the principle admitted, I recognise the propriety of many sorts of arrangements. Many men, many minds. For some, a single life; for others, marriage, early or late, as propriety may point out and circumstances permit. Each must make his or her own rule, as best he can. But, for all, as much freedom as is fitting, consistent with right. A lover of just liberty, I hate undue restraints. Loving law, respecting the rights of others, I hate all that which dictates and binds down where God and nature have left free, especially that conventional restraint in fashionable life on early marriages because forsooth the couple cannot live in the accustomed style, and also that other tyrannical restraint which gives to large numbers of men and women the unauthorized command, "Thou shalt not marry."

The control must be of self, not of others; and it is for each individual to carry it out in his own way. The principle of moderation is not only generally indicated by natural conditions, but is also specially suited to the British character; and has contributed in many things to British strength and prosperity. All the world over, in every circumstance, adventure, or danger, our countrymen are preeminent both in action and endurance. Are such qualities fostered by self-control and self-mastery? Or shall we heighten them by recurring to Gallic models and "common-sense practices," whose advocates dare not explain them openly?

One more word, and I have done. Let me not be held to favour license because I speak for liberty,—scepticism, because in a medical journal I argue from natural conditions alone, or over-restraint, because I point out the paramount importance of that which was from the beginning of time, government by law. And let me, as a man much older than those mingling in the arena of this controversy, venture to impress on all, whatever the practice in this matter which they are able and think it right to adopt, to do and to advocate that alone which their innermost consciences approve, and which they are quite sure they will never have to regret at the last.

I remain, Sir, your obedient servant,

W. E. C. NOURSE, F.R.C.S.

Brighton: November, 1869.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having, though not of your profession, the privilege of reading your instructive Journal, I was prompted by some of its contents in several numbers to address you. Feeling,

however, the delicacy of the subject, and conscious of my own incompetency to measure my mere pen against the sharper instruments handled by your other correspondents, I shrank from the thought of so unequal an encounter. If I have returned, after all, to my first impulse, or it to me, let not my apparent rashness be counted for real temerity, but kindly set it down to a simple sense of duty. What I shall advance may be weak and ineffectual; but, as divines say, I shall have delivered my own soul.

The question that has laid hold of my mind and conscience is that respecting the size of families. J. D. M. makes the nearest approach to the expression of what I think truth and duty; but he hardly speaks out enough for me to feel acquitted through him. I believe with him that a certain chastity and moderation become even the marriage bed, and that, in proportion as the connubial state is entered into by men and women of well-ordered minds, their amenities as man and wife will be duly regulated by the compound nature of the species, as physical, mental, and moral. When wedlock is turned into a mere means of sensuous gratification, it is both degraded and abused. Parents, from a false delicacy, allow their boys and girls to become men and women, husbands or wives, without instructing them in matters relating to that commerce of the sexes which results in the multiplication of the species. We talk [much about education; our system, or no system, of training, has no defect more regrettable than this. Let it be supplied, either by the father to his sons, or by the mother to her daughters, or by the medical attendant on the family to both, or by putting into the hands of each, at the suitable time, a grave, concise, but thoroughly good explanation of the functions with which they are endowed according to their sex, and of the duties that await them in the exercise of those functions. I need not further explain; every man of science will apprehend me. Such measures of precaution as I propose would prevent much sin, obviate much temptation, and get rid beforehand of incalculable misery.

What more I have to say relates to the things meant under such phrases as "marriage-bed check," "avoidal of impregnation," "be abstinent," "innocuous artifices," "French life," "a celebrated Scripture character," "*fraudes dans l'acte de génération*," "some practical plan," and so forth.

I will not pretend not to understand these phrases; nor will I hesitate to condemn what I conceive to be meant by them. I am not prepared to argue the matter scientifically with medical men, but a sneer at "transcendental theological absurdities" shall not deter me, though neither a doctor of divinity nor one of medicine, from denouncing the thinly disguised scheme (if you will suffer me) as founded upon a daring and detestable violation of nature. The French phrase cited above is, in itself, a condemnation. "The act of generation!" Why, then, interpose between cause and effect? I import no "theological absurdities" into the question. I am content to affirm that the concealed proposal is unnatural, unscientific, unphilosophical, any thing that a mere reasoner may be willing to admit has, either negatively or positively, to do with the matter. It cannot be denied that a sensation of pleasure attends the act of sexual intercourse; but it is plain that the allurements to the act and the act itself must have been designed for the simple and exclusive purpose of procreation. Will no competent physician or physiologist come forward and speak the truth on this question? Let a man part with what is or should be the seed of another life in any other way than that which tends at least to its becoming fruitful; and will not his health suffer, in kind if not in degree, as though he had done what is known by the name of "self-pollution?" Let a woman allow herself to be persuaded to join in baulking nature of her plain intention; and will she not be one step at least of the way which has led so many of her sex, first, to the procuring of abortion, and, at length, to downright infanticide? I have done.

I am, Sir, yours, &c.,

A LAYMAN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will Dr. Charles Drysdale, and those who think with him, allow me respectfully to inquire whether they believe the Christian Scriptures? I ask because some of their utterances seem to be considerably at variance with the teachings of those writings which most of us have been taught to regard as *sacred*, and which we believe in as the only safe guide in all questions of morality or "social science."

If their answer be in the affirmative, then I beg they will be so good as to show us how they explain the following passage (from 1 Corinthians vii.), and how they reconcile it with the opinions as to limiting population to two, &c., "like as is done in France," or in any other arbitrary and politic manner:—

"Let the husband render unto the wife due benevolence—likewise also the wife to the husband. The wife hath not power of her own body, but the husband. Likewise also the husband hath not power of his own body, but the wife.

"Defraud not ye one another, except it be with consent for a time, that ye may give yourselves to fasting and prayer; and come together again, that Satan tempt you not for your incontinence."

I might adduce many other passages from the Holy Scriptures bearing on the same subject, but the one quoted seems (if admitted as authoritative) clearly to supersede all the elaborate arguments and suggestions which have been adduced. Some of the latter are quite repulsive, and repugnant to all ordinary ideas of morality.

If they should reply in the negative, *i.e.*, that they do not believe in and take for their guidance in such matters, the Christian Scriptures, I leave you to deal with their future contribution, as you think right. I write for information (at least, such is my chief motive) on a subject which, possibly, may have important bearing on the future social condition of civilised life.

I am, Sir, yours respectfully,

A DISPENSARY DOCTOR (WITH A SUFFICIENTLY LARGE FAMILY FOR HIS INCOME).

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I hope the discussion of this important question will not be allowed to drop until some practical result has been attained. It is a matter of greater importance to the professional and upper classes than to the lower, to whom children are often an assistance at an age when education is a heavy drain upon the resources of their superiors.

There appear to be three means of limiting the numbers of a family, which may be distinguished as the mechanical, the medical, and the moral. Of the two former we can only say that we have no desire to extend the practice of the Continental and Transatlantic systems, however effectual they may be, when calculated to undermine the purer principles of English domestic life.

The moral system is the only one open to discussion; and if the theory referred to by your correspondent *Medicus* is well founded, an immense step has been gained. The habits of married life in this country render such self-restraint as would be necessary to prevent procreation impossible in the majority of cases; but, if assured that nature has provided means for gratifying natural desires without violation of Divine laws and with impunity, there are few who would not exercise the requisite self-restraint during limited periods; and this could be adopted without the risk of extending the practice of illicit intercourse, which other plans would facilitate, for it is practicable only in the sacred confidence of married life, where both have the same interest and would be disposed to unite for the purpose.

Dr. Drysdale, in his reference to "*Prudentia's*" letter, discusses the subject of prostitution. I differ from him in some respects, but think the two questions have much bearing upon each other; for if habits of self-restraint are acquired in youth, in maturer years they will become natural; and it is to the rising generation we must look for any effectual check to the increase of population.

These habits are opposed by the existing practice of prostitution—the subject must not be mentioned to ears polite, but in the private hours of our youth is discussed freely, and there is no other of which it may be said with greater truth, a little knowledge is a dangerous thing. I think it may be considered whether additional restrictions should not be placed upon the exercise of their calling by such women. I would suggest that by a system of registration—I use the word advisedly, as contradistinguished from licensing—something could be done to remove the facilities for the excitement and gratification of the passions of youth.

Could not a short Bill be introduced into Parliament to provide for the registration by the police of houses used for immoral purposes, or in which two or more known prostitutes reside?

The machinery for visiting, &c., is already provided by the Lodging Houses Act, and I think by this means, by the registration of the names of the occupier, owner and freeholder, and by requiring under penalties that the words "Registered under the Act —, Chap.—," and with the registered number, should be painted on a conspicuous portion of the doorway or entrance, as is done over the entrances to places of amusement, &c., something would be done to effect the desired object.

Such houses abound in all large towns; many of those in London are on the property of noble lords who are ignorant, or appear to be, as to the purposes to which they are applied; such ignorance could not continue under a proper system of registration, while the law would annul any contract of lease as opposed to public morals, and afford ample powers to the respectable inhabitants to remove such nuisances from their neighbourhood.

As such characters would thus be driven from respectable localities and compelled to herd together in places which would soon become notorious, where they must be sought, I think one great temptation would be removed from the paths of the young of both sexes, and a great gain to public morals ensue.

F. L.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The following extract from a medical work may be of use in throwing some light upon the subject under discussion in your columns:—

"An interesting and important, though difficult and rarely discussed point in physiology, is the relation of the generative apparatus to the moral character, and the degree in which the former is subservient to and regulated by the latter. I think it would be found that it is so to a very great extent—greater perhaps than is usually recognised; and it is desirable that practical men should pause awhile upon a question of this sort, and not hastily commit themselves to opinions which may have much influence upon the well-being and happiness of society. There are no organs so much under the control as those of generation. Their functions are neither directly nor indirectly in the least essential to life, scarcely even to the well-being of the body. Indeed, which is more remarkable and unusual, they are scarcely essential to the maintenance of the structure of the organs themselves in perfect integrity. The functions of the testicle, like those of the mammary gland and the uterus in the female, may be suspended for a long period, possibly for life, and yet its structure may be sound and capable of being roused into activity. In this respect its qualities peculiarly adapt it for subserviency to man's moral nature. Not that it always yields a tame and willing submission: by no means. That stern struggle between the moral and the physical is one of man's greatest trials, and it is some satisfaction to know that if the victory be with the moral, it is not necessarily at the expense of the physical, but a positive good to both is achieved!"

I am sure you will agree with me, that the above remarks include some very important considerations: and if the writer does not clear the ground, he at least suggests how one part of the difficulty may be got over.

I shall be curious to see what your correspondents say on the subject of this extract.

I am, Sir, yours, &c.,

PHYSIOLOGIST.

ON THE CAUSATIVE AGENCY OF THE SKIN AND LIVER IN THE INDUCTION OF PHTHISIS AND OTHER SCROFULOUS MALADIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Under the above heading, in your issue of the 29th September, kindly forwarded to me by my brother, I find some remarks on a paper of mine which appeared some time ago in your valuable journal, by Dr. Luther, in which, as I think he hardly does me justice or interprets my article correctly, I beg you will give me an opportunity to set forth some of my views on phthisis in a clearer light. Dr. Luther says I assert oxygenating remedies cure phthisis, and quotes Dr. Savary to show that drugs rich in oxygen have been given under a misconception, from a visionary notion of furnishing that element to the blood. If he will have the courtesy to look again at my paper he will, I am sure, do me the justice to admit that it is not on the influence of oxygen in its ordi-

nary condition, but on oxygen in its more active allotropic state, ozone, I rely, as the following passage will testify, "At the same time we must inculcate daily ablutions of the entire body, open-air exercise, remove acidity by promoting oxidation, guard against unfavourable atmospheric influences and the occasional dearth of ozone by keeping the blood, as I may be permitted to say, ozonized, by potassa permanganas, which, according to Schönbein, contains two or three atoms of oxygen in that allotropic condition." This preparation possesses also the advantage of being a capital tonic, manganese being but little, if at all, inferior to iron in that respect. I invariably prescribe it on an empty stomach, but to females, who may object to its taste, I have given it on sugar, and I maintain that it is not decomposed thereby. At the present time I have a solution of the salt, into which many hours ago I dropped a portion of sugar without in the least altering or affecting its beautiful colour. Nondiscolouration evinces non-decomposition. The observations and reasonings which led me to look on ozone as a remedial agent in phthisis are capable of being either verified or shown to be fallacious by any one who takes the trouble. Having observed that the symptoms of a patient suffering from vomica appeared to be obviously influenced by atmospheric causes, I set about the investigation of the meteorological agencies, which, coinciding with the most conspicuous fluctuations of the patient, might reasonably be looked on as causative of them. By a careful comparison of the meteorological conditions which corresponded to an amelioration or an aggravation of the disease, determining this by the temperature, respirations, pulse and cough, &c., I came to the conclusion that electricity and ozone were the two chief factors in the modification of my patient's symptoms. I found an entire absence of ozone, or its marked diminution, correspond to an exaggerated cough, night-sweats, heightened temperature, &c., and an abundance of ozone coincident with a general improvement. The prevailing electrical condition of the atmosphere appeared to me to wield an equally obvious influence over the state of my patient (the ozonic condition being the same). The positive was beneficial, the negative injurious. The + El, with abundance of ozone, markedly ameliorated the symptoms. The — Elect, with diminished ozone, coincided with the catching of a fresh cold. The + Elect, with — ozone, or the — El with + ozone produced little or no effect, the influence for evil of the one being neutralized by the contrary effects of the other. Hence my inference—ozone is beneficial, its absence prejudicial; deduction—ozonize the blood. Positive electricity is serviceable, hence I endeavoured to supplement the enfeebled nerve power by the generation of thermo-electric currents, produced by the action of alcoholic drinks on the nerve tissue. Lallemand, Ferrin, and Duroy have shown that alcohol possesses for nerve tissue a remarkable elective affinity, seizing on the water of which it contains 80 to 85 per cent., it naturally produces condensation and liberation of heat, whereby the electric equilibrium of the cells becomes disturbed, and thermo-electric currents are generated; just as we see, produced by the unequal heating of a metal or of different metals, as in the apparatus of Marcus. This is not altogether an hypothesis, but is capable of demonstration, and I advance it on the results obtained by a series of experiments extending over two years not yet completed. By supplementing the enfeebled nerve power the functions of the system will be more healthily carried on, and the expenditure of nerve force thereby husbanded. The nervous centres, by the improved assimilation which must necessarily follow, rapidly recover from the enfeebled condition into which they have fallen. At the same time I never forget that alcohol, under certain circumstances, is capable of acting chemically on the nerve substance, and accordingly prescribe it in moderation. In addition, I, basing my practice on a series of experiments, prescribe veratum viride to calm irritation, remove irregular muscular contraction, soothe excitability, and enable the potassa permanganas to raise the effete materials to a higher condition of oxidations of more facile elimination. Accordingly, when the symptoms of acidity are well marked, when the tongue is red and dry, and the patient is constantly striving to keep it moist by stimulating the salivary glands by those movements of the lingual and buccinator muscles which produce a characteristic smack, when there is a poor appetite, nausea after eating, and tenderness on pressure at the epigastrium, I have found it especially useful. Also in the case of vomica containing much fluid, with harassing ineffectual cough, veratum viride is invaluable.

The two cases I selected for my paper fully illustrate the

value of my treatment. The 1st, showing the influence, not only over tuberculosis *sine vomica*, but with a grave secondary complication—epilepsy. The 2nd shows the expulsion of crude tubercle from one lung, and the filling up of a cavity in the other. Invaliding from a foreign station is not invaliding out of the service.

If Dr. Luther should not have the time to repeat my experiments, I think he will find corroborative evidences of their validity in a consideration of the following facts agreed upon by all.

1st. In the benefits derivable from residence in elevated localities. It is well known that the evidences of ozone increase with elevation, a fact which goes far to explain the increased elimination of carbonic acid, observed by Jourdanet on the plateaux of Mexico at a height of 2,000 metres, (the inhalation of oxygen remaining the same). The same observation applies to atmospheric electricity, "*C'est dans les lieux les plus élevés et les plus isolés, qu'on observe le maximum d'intensité*" (Ganot).

2nd. The immunity from the disease enjoyed in the Hebrides ascribed by Dr. McNabb to the abundant evolution of oxygen by marine algae, must be considered along with the observations of Kossman and Daubeny, that a large proportion of oxygen is converted into ozone at the moment of elimination by plants. And of Lieut. Chimmo who found a greater abundance of ozone at the Hebrides than in any other locality.

3rd. Residence in cities is notoriously unfavourable, here it is well known ozone is used up by respiration, and decomposing organic materials. In cities also electricity disappears, "*Dans les maisons, dans les rues, sous les arbres on ne remarque d'aucune trace d'électricité positive*" (Ganot)." Dr. Richardson found the oxygen of an apartment so spoiled by respiration, as to become in time unable to support life, incapable of being restored to its normal condition by the abstraction of the carbonic acid gas present, it is immediately rendered active by ozone or electricity.

4th. Easterly winds are prejudicial. May not this be explained by the observations of Dr. Moffatt, who found during a series of experiments made between Lat. 52° N. and 39° S., and Long. 83° E. and 25° W., that ozone disappeared when the wind was between North and East? I do not think Dr. Luther and I differ much in regard to the condition of the blood, for he says, "I dwell much on the acidity of the blood, and after enumerating its many other mischievous effects, *videlicet*, preventing oxidation." Here is an admission that oxygen is required, increased oxidation necessary.

I also agree with Dr. Luther that hepatic derangement adds its share to the morbid processes engaged in tuberculosis, but I look on hepatic as well as pancreatic disordered action as secondary, not primary. Bouchardat's views need substantiation. By irritation of the vasomotor nerves, I conceive the formation of bile in its normal quantity impeded, and to the diminution of this secretion I attribute the falling off of the hair and the rumbling in the bowels of phthisical subjects, inasmuch as similar results were observed by Dalton in dogs in which he established biliary fistula. I also agree with Dr. Luther in considering warmth as essential, but am of Dr. Cormac's opinion that pure air is at all times desirable.

From the conclusions that Dr. Luther draws from a bird's putting its head under its wing when about to sleep I am obliged to dissent, inasmuch as I cannot consider such an act demonstrates "That such pure air is not required by night as by day," but rather the opposite; inasmuch as if the act has any influence at all on respiration it must be such as would be exercised by a respirator, and we know that respirators are only required when some atmospheric impurity exists. Neither do I think warmth is the sole object sought to be attained thereby. For my canary, hung close to the fireplace, invariably goes to sleep in this way. I think the act is entirely instituted for the induction of sleep. The bird excludes the rays of light just as the old gentleman does when he throws his handkerchief over his eyes to take forty winks in his easy chair. For birds do not wait for night to allow nature's sweet restorer to steal upon them. Fishes seek the shade of the bank, nestle amongst the weeds, or hide themselves under stones when about to take a midday nap.

The coatmundy covers up its eyes with its long tail when about to sleep on the hearthrug. Moreover, in the case of birds, sleep is probably further promoted by the flexion of the neck producing cerebral venous engorgement. Everyone accustomed to travelling must have experienced a tendency to doze when looking at the scenery as he flies along in a railway.

carriage, if he retains his seat and looks over either shoulder, although a cool breeze may be blowing at the time. Apologising for the length of this communication,

I am, dear Sir, yours, &c.,

JOHN MULVANY, Assiat. Surgeon Royal Navy.

H.M.S. Martin, Ryde, I. W., Nov. 4, 1869.

Medical News.

UNIVERSITY OF LONDON.—The following are lists of the candidates who have passed the recent Sec. M.B. examination for Honours :—

MEDICINE.

FIRST CLASS.—Evan Buchanan Baxter (Scholarship and Gold Medal), King's College; Thomas John Davies (Gold Medal), University College; William Richard Gowers, University College; James Reginald Stocker, Guy's Hospital.

SECOND CLASS.—Clement Dukes, St. Thomas's Hospital; Herbert Lumley Snow, Queen's College, Birmingham, and University College; Ethelrid Desse, University College; Edwin Rayner, B.A., Paris, and University College.

THIRD CLASS.—Henry Flamank Marshall, Birmingham General Hospital, and University College; Edward Francis Willoughby, University College.

MIDWIFERY.

FIRST CLASS.—John Davies Thomas (Scholarship and Gold Medal), University College; Evan Buchanan Baxter (Gold Medal), King's College; Clement Dukes, St. Thomas's Hospital; James Reginald Stocker, Guy's Hospital; Edwin Rayner, Paris, and University College.

SECOND CLASS.—Herbert Lumley Snow, Queen's College, Birmingham, and University College; William Richard Gowers, University College; Edward Francis Willoughby, University College; Thomas Alpheus Buck, Guy's Hospital.

FORENSIC MEDICINE.

FIRST CLASS.—James Reginald Stocker (Scholarship and Gold Medal), Guy's Hospital; Edwin Rayner (Gold Medal), Paris, and University College; Edward Francis Willoughby, University College.

SECOND CLASS.—Herbert Lumley Snow, Queen's College, Birmingham, and University College.

THIRD CLASS.—Thomas Alpheus Buck, Guy's Hospital; John Davies Thomas, University College.

The following are lists of the candidates who have passed the recent examination in Medicine and Surgery :—

M.D. EXAMINATION.—(ENTIRE.)

Edward Casey, King's College; John Cavafy, Westminster Hospital; Henry Clothier, University College; Reginald Eager, Guy's Hospital; Henry Charles Hilliard (Gold Medal), Guy's Hospital; Thomas Richardson Loy, University College Hospital; John James Ridge, B.A., B.Sc., St. Thomas's Hospital; Edward Thomas Tibbits, University College.

LOGIC AND MORAL PHILOSOPHY ONLY.

Carey Pearce Coombs, St. Mary's Hospital; Henry Franklin Parsons, St. Mary's Hospital; William Alsept Richards, King's College; Edward Wynne Thomas, University College.

B.S. EXAMINATION.

FIRST DIVISION.—Clement Dukes, St. Thomas's Hospital.

M.S. EXAMINATION.

Thomas Mitchell, M.D., London Hospital.

APOTHECARIES' HALL.—At a Court of Examiners held on the 25th ult, the following gentlemen, having passed the necessary examinations, were admitted licentiates of the Society of Apothecaries, viz :—Messrs. Robert Gray, Armagh; Charles Oakes, Bayswater; J. W. Pinder, Leeds; and E. A. Waterworth, Newport. At the same Court (the 25th), Messrs. W. M. Noot, Middlesex Hospital, and T. H. F. Tothill, St. Bartholomew's Hospital, passed the first professional examination.

MESSRS. Macmillan & Co.'s new weekly, *Nature*, announces that the three annual medals of the Royal Society have been awarded thus :—The Copley medal to M. Regnault, one of the first among the many living French physicists and chemists; one of the Royal medals to Dr. Mathiessen, distinguished for his chemical and physical researches; while Sir Thomas Macleat, the Cape astronomer, with whose valuable contributions to science all are doubtless familiar, carries off the other. The medals were presented yesterday, at the annual meeting of the society.

We clip the following curious announcement from the *Gazette* of last week :—“The physicians, and Dr. Ricord at their head, are unanimous in declaring that the late illness of the Emperor, far from impairing his health, has, on the contrary, consolidated it. ‘His Majesty,’ says that eminent practitioner, ‘has found in the struggle with his malady, a

fresh and unexpected force. Pay no attention to fantastical and malevolent diagnostics; it is not the Emperor who is most surprised at this issue of this crisis; it is I.”

THE SEASON IN CORNWALL.—In the immediate neighbourhood of Penzance may be seen two or three apple trees in full bloom, while not only is the same evidence of the mildness of the season presented at Gerrans, but in the garden of Mr. Johns is a long row of peas, about 4 feet high, in full flower. Ripe strawberries have been gathered in several gardens; and at Pentewan, near St. Austell, many fine ripe raspberries, a few measuring from 2 inches to 2½ inches in circumference.—*Times*.

A REMARKABLE FAMILY.—There expired at Talskiddy, St. Colomb Major, Cornwall, on Saturday, Joan Tonkin, aged 96, whose faculties continued good to the last. She leaves 10 children of the united ages of 623 years, 49 grandchildren, and 98 great grandchildren. The deceased's husband, who was a farm labourer, lived 42 years on one farm at the weekly wages of 7s., notwithstanding which, no member of the family ever received parochial relief.

LONDON FEVER DENS.—The Vestry of Clerkenwell have lately come to the resolution to demolish the whole of a “property,” a block of buildings lying between Frying-pan-alley and Bit-alley, known as “Jack Ketch's warren.” The Sanitary Committee of the Vestry had reported that they quite agreed with the medical officer and surveyor of the parish, who had condemned the place as unfit for human habitation, and recommended the Vestry to demolish the houses, notwithstanding that owners and solicitors to owners had denied the right of the Vestry and had given notice of appeal to the Quarter Sessions. One member of the Vestry, Mr. Franklin, declared that the “warren” was composed of pest holes, and a source of trouble for years as a breeding-place of fever. Mr. Palmer said he had been in London all his life and had never entered a block of houses in such a terrible condition, and the place, fraught with misery to all its inhabitants, was the breeding-place of everything which was evil, it being obscured, without light or ventilation, and nothing but a fever-generating hole. Mr. Brooke expressed his delight at the prospect of having the “accursed spot” removed, for there had been attempts over ten years to remove a place where the squalid misery was heartrending to look upon. Several members objected to the action of the committee as being too hasty, and eventually a delay was obtained for the purpose of seeking counsel's opinion with respect to the powers of the Vestry. This opinion was given in favour of the Vestry, and orders thereupon issued for the demolition of the warren.

WE recently had occasion to notice and expose the fallacious assertions of an anonymous correspondent of the *Lancet* in reference to the surgical appointments at the Royal South Hants Infirmary. The statements made by him called forth an emphatic protest from Dr. Hearne, addressed to the editor of the same journal, and with his signature appended thereto. We observe that in the last number of the *Lancet*, the receipt of a communication is acknowledged as coming from Dr. Hearne, and in another column is the following announcement :—“F.R.C.S. (Southampton). We regret that the pressure on our columns prevents the insertion of our correspondent's lengthy communication.” Presuming that both these notices refer to one and the same thing, is it exactly consistent with the etiquette of journalism to treat as an anonymous communication that which is acknowledged in another form as bearing the personal *imprimatur* of the writer? Is it, moreover, consistent to give publicity to anonymous assertions, and then to deny the same publicity to an exposure of their fallacy, made in the name, and therefore upon the direct responsibility, of the correspondent who personally impugns their veracity?—*Southampton Times*, Nov. 27.

THE LATE DR. EASTLAKE.

It is with much sorrow that we have to announce the death of this talented and estimable physician, which took place at Paris on the 17th of last month.

At a time when a good and lucrative practice seemed opening out well before Dr. Eastlake, he was brought down to the extreme of debility by an attack of typhoid fever, followed shortly by a bad attack of rheumatic

fever; and thus he was completely laid aside from work during the whole of last winter, being attended most assiduously by his friends Dr. Scott and Dr. Gee, with whom were afterwards associated Dr. Walshe and Dr. Harley.

The attention and skill of these physicians brought their patient through a most dangerous crisis of disease, and in the summer Dr. Eastlake hoped to derive some good from a stay at Buxton. In this he was disappointed, for the weather at the time was cold and wet, so that in September Dr. Eastlake returned to town very little benefited.

Arrangements were then made for a winter in the South of France, and it was while on the journey thither that the hand of death was laid upon the doctor during his sojourn in Paris.

Dr. Eastlake received his early education at Westminster School; he subsequently studied in Edinburgh, Dublin, Paris, and Wurtzburg, and was an M.A. and Ph. D. of Heidelberg.

He was a Fellow of the Dublin College of Physicians, and a member of numerous learned and distinguished societies both in this country and abroad. Among various honorary appointments he was Physician to the British Lying-in Hospital, and Physician Accoucheur to the St. Marylebone Dispensary in Welbeck Street. As an author Dr. Eastlake contributed many short but useful articles to the journals, and to the transactions of the Obstetrical Society. One of these latter contributions on the management of the third stage of labour was reprinted as a pamphlet, and as such received much commendation and praise.

CONSUMPTION HOSPITAL, BROMPTON.

THERE is another vacancy at this Hospital caused by the resignation of Dr. Scott Alison, who for the last thirteen years has filled with singular diligence the office of physician. We are glad to note that the committee speak in an appreciative manner of the loss the charity will sustain by the retirement of Dr. Alison, whose kindness to patients, unquestioned skill and learning, exactitude and punctuality in the discharge of his duties, and courteous bearing have secured him the good will of his Professional brethren, and the confidence of a large clientelle. We sincerely trust he may long live to reap in private practice the reward due to his public services. His work on "Diseases of the Chest" is one of great originality and power, and promises that other material, of which he must have accumulated a store, may yet be given his Profession. We are glad to say that our own pages will again be embellished with contributions from his pen.

MANAGEMENT OF LUPUS ERYTHEMATOSUS.

W. H. Geddings, M.D., of Aiken, South Carolina (*Am. Jour. Med. Sciences*), in an extensive paper "On Lupus Erythematosus," coincides with Professor Hebra in the view that *lupus vulgaris* and *lupus erythematosus* are two separate and distinct diseases, in no way connected with each other. He regrets that Professor Hebra ever relinquished the name (*Seborrhœa congestiva*), which he first applied to lupus erythematosus.

The fact that lupus erythematosus occasionally gets well of itself, leaving only a flat thin cicatrix, admonishes us to be careful in the selection of remedies, and not to make use of those caustics which produce thick and uneven scars. The first step is to remove the scales, for which purpose strips of linen soaked in oil should be applied to the diseased surface, over which a piece of flannel should be bound. This application is to remain on until the scales become so soft that they may be rubbed off with ease. The following application may be made:—Moisten a piece of flannel with lukewarm water, and lay a small quantity of the soap upon it, and then rub the diseased patch with it until a good lather is formed, after which some of the soap should be spread upon a piece of flannel and laid upon the diseased surface. The frictions are to be repeated daily, reapplying the flannel after each operation. After the third day the treatment should be sus-

pending; and a new epidermis allowed to form. As soon as this has taken place, the part should be well washed with water, to determine whether the new epidermis is healthy. If it stand the washing, the disease may be considered cured; if not, the whole process is to be repeated. This simple treatment will in some few cases effect a cure; but in the majority it will be found necessary to resort to more energetic remedies. Hebra has sometimes effected a cure by cauterizing the part with strong liq. ammonia. It should be applied with a brush made of picked lint. After each application the diseased surface pours out a fluid not unlike that which we see in a case of eczema. The ammonia should be applied daily. Another application is a solution of iodine in glycerine. R. Iodini ℥j., Glycerine ℥j., Potass. iodid. ℥ss. M. It should be applied 3 or 4 times daily, until a thick brown crust falls off and enables us to see the condition of the skin underneath. Should it be necessary, the caustic should be reapplied. The application of iodine and glycerine is exceedingly painful.

This disease, which is more frequent on women than on men, may be called a rare one. Dr. Geddings has observed it only twenty times in upwards of 3,400 cases of skin disease; that is, in the proportion of 1 to 175. This average would appear to be large, as observations in other years show the disease to be much less frequent.

NOTICES TO CORRESPONDENTS.

Mr. R. M. CRAVEN, Hull.—Is thanked.

H. E. S., Manchester.—You will find the "Pass Lists" in our "New" column.

ANALYST.—The number for June 23rd containing the summary of our reports upon "Cocœa and Adulterations," is out of print. We propose shortly to reprint the whole series of analytical reports.

Dr. CHAS. TAYLOR, Nottingham.—You will find the letter of Dr. Ewing Whittle in page 447, May 26, of the present year, and the article by Dr. Drysdale to which that refers in the previous number, pp. 411-412.

The following original communications and letters are unavoidably left over till our next: F. S. A. on the Multiplication of Mankind; on a Sling for Treatment of Bed-sores, &c. By Surgeon Porter, 97th Regiment; case of Clonitis treated by Magneto-Electricity.

Dr. Woods will feel much obliged if the Editor will inform him whether the Dictionary of Chemistry (Wurtz's) reviewed in this week's Press is translated or only still published in French? Parsonstown, November 26, 1869.

Wurtz's "Dictionnaire de Chimie" is not, nor is it probable that it will be, translated into English. The introduction, however, which forms a complete monograph by itself, has been translated by Henry Watts. It is from the pen of M. A. Wurtz, and entitled "A History of Chemical Theory, from the Age of Lavoisier to the Present Time." This is published by Macmillan and Co. The Dictionary is published by L. Hachette et Cie, Paris.]

ON A SLING FOR TREATMENT OF BED-SORES ON SACRUM OR NATES, WHEN THE PATIENT IS OBLIGED TO REST IN THE RECUMBENT POSITION.*

By Surgeon PORTER, 97th Regiment.

SIMPLE as this contrivance, here presented in a rough sketch,† for the treatment of bed-sores may appear, I feel I am justified in bringing it before this Society, in consequence of the success experienced by its use in a case lately under my care, the particulars of which I beg to detail.

A sailor of H.M.'s — having received a severe injury of one of his ankles, was detained for a considerable time at a Sailor's Home and elsewhere, in hopes of recovering, which did not take place. On being handed over to my care, I found the lower ends of tibia and fibula in a state of caries, also the os calcis and astragalus. His condition was very low, and an extensive deep bed-sore over the sacrum and nates had formed, accompanied by a profuse foetid discharge. Amputation being considered the only means of saving his life, I performed the operation below the knee. A few days after the operation the stump presented an unhealthy appearance, there being a copious thin discharge from it, and his general health was on the decline. These symptoms I attributed to not being able to keep the bed-sore properly clean or dressed, in consequence of its being necessary that the stump should not be disturbed. The smell from the patient was most offensive. Air-cushions and pillows were of no use, in fact, worse than useless, as they became saturated with the discharge, and the former, from the nature of the material, heated the parts to which they came in contact, and in-

creased the offensive smell. Before amputation was performed the patient had been placed in a three-pole hospital marquee. As it was quite impossible other patients could remain in the same ward with him, I therefore took advantage of two of the poles to attach the sling. Twenty-four hours after I commenced its use, there were evident signs of improvement in my patient, who for the first time for a considerable period had refreshing sleep. The discharge from the stump had decreased and was more healthy looking, and there was little or no smell about the marquee. For eighteen days he was constantly on the sling with this result, that the stump healed and the bed-sore rapidly granulated. It was, of course, discontinued when the patient could alter his position without danger of injury to the stump. The sling consists of a strip of strong West of England canvas, 18 by 24 inches; at either end it is stretched on to pieces of strong wood about the diameter of the common round office ruler, which keep the canvas expanded when under the patient, and form means of fastening stays, which are spliced together and attached to three-inch blocks. These blocks have ropes passing through them, and blocks attached to the poles, by which means the sling can be raised or lowered. A piece of canvas, round in shape and six inches in diameter, is removed from centre of canvas, through which opening the sore is to be dressed and cleaned. In applying the sling it is necessary to place a doubled mattress or a pillow under the patient's shoulders extending to the loins, and a pillow under the knees.

Having experienced great difficulty on active service and in India in the treatment of bed-sores, from want of proper means of keeping pressure off them and preserving cleanliness, I venture to hope that this sling may be considered worthy of trial in camp hospitals, where advantage can be taken of the marquee poles, and as further advantages I beg to point out that it is very portable, not easily put out of order, and of moderate cost. To adapt it for a hospital ward it is only necessary to construct temporary uprights, which could be let into sockets in the floor and made secure by stays. My not being an artist will, I trust, be sufficient excuse for the imperfect condition of the sketches.

* This paper was read before the Army Medico-Chirurgical Society of Portsmouth, 3rd Nov., 1869.

† A sketch of the contrivance was handed round.

GLOSSITIS TREATED SUCCESSFULLY BY MAGNETO-ELECTRICITY.

(Under the care of Dr. ANDERSON, of Newtownhamilton,
Armagh.)

J. McG., aged twenty-three years, a stout healthy man, of swarthy complexion and regular habits, came to me on the 5th of November, complaining of pains in his neck in the parotid and tonsillar regions, and a difficulty of swallowing. He did not refer any pain to his tongue, and on examination I could not discover any mischief going on in the mouth or throat, and sent him home "to see if he would become ill." On the 6th, the pain continued and the tongue began to swell and redden, and coated with a clammy sordes: he felt as if it would stick to his jaws. To clean his mouth and remove the foul odour of his breath, I ordered him a mixture of potassæ chlor., ℥ij.; tinct. ferri mur., ℥ss. to 8 oz. of water, which he used first as a gargle and afterwards swallowed. This, he said, had the desired effect, but it did not serve to cool his tongue or mitigate his pain. On the 7th the swelling and redness increased, and he felt shooting pains through his ears. On the 8th I was called on to visit him, and he was then suffering from great pain. He was in dull spirits—pulse 96—very weak, and his tongue was now three times its own size, and of a deep red colour. His mouth was gasping wide, and the tongue, not having room enough, was slightly protruded. He was unable to articulate a single word, and I was in dread that suffocation might soon seize him. As he had eaten nothing since the 5th, and when he found it impossible to swallow even my simple mixture, I thought the sooner I could reduce the size of his enlarged "unruly member" the better. Passing over pressure as inadmissible, and incisions, and such caustics as carbolic acid, cupri sulph., and argent nit., which had been used a day or two sooner, might have rendered a "painful" relief, I had recourse to the magneto-electric machine, which medico-galvanists assert will cure anything but death, and which is especially supposed to restore the equilibrium of nerve force, the want of which, according to some pathologists, is the cause of all inflammatory disorders. On the evening of the 9th I attached two long thin pieces of sponge to the metal conductor of the machine, and passed a current of electricity into the tip and edges of his tongue, which was now of an enormous size. That night as he had done previously, he swallowed, by means of the gravitation of the fluid, a black draught, slept well, and the next morning, to my astonishment, he was able to swallow a bowl of oatmeal gruel. When I saw him first that morning he told me he felt as if there was a new tongue in his head—that he was almost free from pain. He could now speak so as to be understood, and could roll the tongue about in his mouth. The shooting pains had left his ears, and the mouth was secreting saliva in place of "sordes." This sudden improvement gave me courage, and I applied the current again. In the evening he returned with his tongue still nearer "the truth," and I repeated the application. The next morning, thirty-six hours after the first "shock," his tongue was of the normal size and feeling. Nosologists tell us that idiopathic glossitis is a rare disease, and especially rare as an uncomplicated affection. Its decrease of late years is doubtless owing to the partial abolition of "coursing" with mercury to salivation. When it arises in practice, and its course cannot be traced to this old mode of "jobbery," we are more ready to trust in any specific remedy. The causes are diminished, and hence the modes of cure are limited. What would check the inflammation of tongue arising idiopathically might fail to make the same impression on glossitis caused by mercury. In the latter case we would have asthenic inflammation owing to the destruction of the red globules of the blood; in the former the inflammation would be sthenic. To assert that magneto-electricity would act like magic on mercurial glossitis would

be to assume that it reproduced the red globules of the blood; to say that it cut short an acute attack of idiopathic glossitis which would probably have ended in suppuration, only implies that it imparted a new tone to that nerve force the excess or defect of which is a primary cause of every species of inflammation.

If second trials should confirm the specific virtue of the electric current as a remedy in idiopathic glossitis, it will bring with it the advantage of an almost painless operation, and exempt the "thick-tongued" sufferer from the annoyance of caustics and the troublesome act of swallowing medicines.

PTYALISM AS A SYMPTOM OF SYPHILIS.

By HENRY LEE, Surgeon to the St. George's Hospital.

A GENTLEMAN had well-marked constitutional syphilis. When I saw him he had not taken a grain of mercury. He was greatly distressed by a copious and constant discharge of saliva from the mouth; this was so great that it glued his whiskers every night to the pillow-case. The gums were red and inflamed, but not very tender or ulcerated. This state of things continued over some weeks without any mercury being administered.

A medical man had constitutional syphilis. He had used no mercury in any form, except an ointment which he occasionally applied to his hair, and which contained a very small quantity. In October, 1868, this gentleman wrote to me, "I don't know what could loosen my teeth and inflame my gums so much. I could not have been cold, as the weather has been so fine."

Another patient of mine whom I have seen for many months has lately had a severe attack of inflammation of the gums with a very considerable increase in the secretion of the saliva without having taken any mercury for upwards of a year. In this case there was, in addition, ulceration of the throat, which was not present in the other cases.

NEW VAGINAL SPECULUM.

At a recent meeting of the Philadelphia Obstetrical Society, Dr. Albert H. Smith exhibited a new form of vaginal speculum, which had been made at his suggestion by Mr. Kolbe. It is described at length in the *American Journal of Obstetrics* for November.

It is in form a bivalve, having a double movement, giving a parallel separation of the blades, and also the ordinary angular separation. This double movement was suggested first by Mr. Robert Ellis, of London, and adapted by him to his "new expanding" speculum, described in the *Transactions of the Obstetrical Society of London* for 1867; but his instrument, so far as appears, has not been brought much into use. Mr. Kolbe recently has made a very neat and simple modification of Ellis', giving a very useful instrument, as compared with any form of valve speculum previously in use.

Dr. Smith's speculum, adopting this principle of a double movement, is so constructed as to act as a double vaginal retractor, having the blades separate throughout their entire length upon one side, and connected by a square bar upon the opposite side, along which the blades slide with an independent motion. This movement is effected by means of a right and left screw placed in front of the bar, passing through the lower end of the pivot-slides which move upon the bar, and to which are fastened the blades. This right and left screw is operated by means of a flat head at one extremity, the turning of which causes both blades to recede uniformly from the centre of the bar, making a parallel separation without any change in the angle of the blades toward each other. The angular movement is effected by the handles of the blades working upon the pivot-joints by which the blades are connected with the bar; and as each blade moves in-

independently of the other, each requires its separate adjustment for retaining it in position; this adjustment being a screw and nut attached at one end to the blade, and the other passing through an eye upon the slide.

The blades are short, being only $3\frac{1}{4}$ inches in length, allowing the cervix to fall forward toward the vulva, entirely within reach of the finger, which condition, with the opening and separation of the blade entirely upon one side, enables the operator to have complete command of the cervix with the finger while the speculum is in position, the vaginal walls being simply kept out of his way, without any interference from the instrument with his manipulations, an advantage which is not found in Ellis' or any other valve speculum, having the vulvar aperture a closed ring.

The advantage of this arrangement will be manifest to any one accustomed to use the speculum, even in the most ordinary cases of uterine disease. This speculum is easily introduced, retains itself without the slightest difficulty, and exposes the cervix to a completeness that no other single self-retaining instrument will do. Thomas' speculum, so much used in New York City, gives an admirable view of the cervix, but requires to be held in position continuously, thus involving either the aid of an assistant or the constant occupation of one hand of the operator. Dr. Smith's speculum may be introduced with the convexity of the blades either antero-posteriorly or laterally; after introduction of the point toward the sacrum, the angular expansion of the blades enables the operator to find the cervix with little difficulty, when the movement of the screw separates the anterior portion of the blades, putting the walls of the vagina upon a stretch allowing the cervix to fall forward in easy reach of the finger which can be brought to bear upon its whole surface as far as the vaginal cul-de-sac. The entire openness of one side of the speculum facilitates the digital examination, as well as the investigation of the condition of the vagina, and especially the urethra and adjacent tissues.

In introducing a sponge-tent, so unsatisfactory an operation through any ordinary speculum, great advantage is given from the opportunity of ocular and digital examination, the tent being grasped tightly by the forceps, and directed by the finger in the vagina, without coming in contact with the vaginal moisture. The passage of the uterine sound is rendered much easier than with the speculum of ordinary length, the uterus not being forced upward and backward, and being allowed more of its natural mobility. In ligating, or excising a polypus or other growth from the cervix, the advantage of combined sight and touch will be very easily comprehended.

Figure 1 represents a profile view of the instrument, with the screw mechanism, as last introduced.

FIG. 1.

Figure 2 represents a profile view of the instrument as at first described in the Reporter.

FIG. 2.

Figures 3 and 4 represent the speculum expanded in the two ways, respectively, of parallel and angular movement, the relations of the blades being the same in both the old and new forms of the speculum.

FIG. 3.

FIG. 4.

Hospital Reports.

METROPOLITAN FREE HOSPITAL.

Cases under the care of Mr. JOHN WARNER.

A FEW days ago we observed the two following cases of eczema in the clinique of Mr. Warner:—

Case 1.—A girl of sixteen came with an eczematous eruption on the face, which had lasted as long as she could remember, and always in the same situation. There was a red and weeping condition of the integument, from each angle of the mouth downwards to the chin.

Case 2.—A woman, aged fifty-two, came with an eczematous eruption of the inner surface of both forearms, nape of the neck, and around the mouth. These eruptions consisted of a reddish surface, moist and covered with brawny desquamatory scales. She was treated for some time with lotio plumbi, and glycerine, which, however, not succeeding, Mr. Warner painted the surface over, as also in the case of case 1, with a twenty grain to the ounce solution of argent. nit., and in both cases administered 5 minims of Fowler's solution *t.d.* after meals.

Case 3.—A woman, aged thirty-five years, married ten years, had, a month after marriage, an eruption, and, some months after, a creeping sore on her face, which has left extensive scars. Never had either children or miscarriages, and was well for many years. When she was nineteen years of age she had sores on privates and eruption, and afterwards a bad leg. This leg has recently again become bad, after an interval of ten years. ℞ Pot. iod. gr. x. ex qq. ʒj. *t. d.*

Case 4.—A woman, aged twenty years, and five months pregnant, had had an eruption three months, roseola, and suffering from mucous tubercles on vulva without alopecia and sore throat, was treated by pot. iod. gr. v. aq. ʒj. *t. d.*

Case 5.—A case of tertiary pustulo-crustaceous syphilide in a woman aged thirty-two, who had been infected three years before, was treated by pot. iod. gr. x. aq. ʒj. *t. d.* Mr. Warner seems to treat all his hospital cases of syphilis, whether primary, secondary, or tertiary, with iodide of potassium. He objects to giving mercury, when unable to watch symptoms, and thus does not often give it to his public patients. We believe that Mr. J. Hutchinson, when at the Metropolitan Free Hospital, abandoned, for experiment, the use of mercury for a considerable period, at which time Mr. Warner was resident medical officer in the hospital.

Case 6.—Mr. Warner operated on a case of prolapse of the rectum on a man aged sixty-five, who had, he confessed, drank a good deal in his life. The prolapsed intestine was first touched freely by nitric acid, and when the slough

separated and the prolapse was slightly reduced, a considerable portion of tissue and hypertrophied integument was excised, the man being under the influence of chloroform. Not much blood was lost, and the parts were dressed with lint dipped in perchloride of iron, which arrested the venous oozing. The patient is much relieved by the operation, and the prolapse is greatly reduced in size.

ROYAL VICTORIA HOSPITAL, NETLEY.

Enlarged Spleen.

DR. MACLEAN tells us that in the Royal Victoria Hospital they have come to regard enlargement of the spleen, the result of malarial fevers, with little concern. Very rarely indeed does it happen that this condition resists the use of the ointment of the biniodide of mercury, applied over the enlarged organ in the same way as it is used in India for the cure of goitre. Since he first invited attention to this mode of treatment he has had every reason to be well satisfied of its efficacy. The biniodide is in daily use in the wards.

The following is a typical example:—

Private Jeremiah Murphy, 86th Regiment, age 28; completed 8½ years of service; invalidated from the Mauritius: admitted 14th Oct., 1868.

During his four years of home service the patient had good health, the same subsequently at Gibraltar and the Cape of Good Hope. At the Mauritius he was attacked by the prevailing fever, from which he suffered severely, having been in hospital there with intermittent fever at one time for twenty-one days, and after discharge "he often had two attacks in one day." It is reported that "his spleen enlarged enormously after every attack."

On admission this soldier was a perfect type of a man saturated with malaria. His skin was a dirty yellowish brown colour; what should have been the "white of his eyes" presented the same colour; his appetite was bad, he was languid, out of spirits, and incapable of any exertion. The spleen was enormously enlarged, reaching beyond the mesial line, and far into the pelvis, girth round the abdomen was 36½ inches. The left lung was pushed upwards by the enlarged spleen; lips, gums, and tongue almost white: heart sounds normal, but feeble. There was an enormous predominance of white corpuscles in his blood; the urine was red, deposited lithates, and contained albumen. The learned Professor says that, "treatment in this case consisted in the external use of the ointment of biniodide of mercury, perchloride of iron, in full doses (which was occasionally changed for the syrup of the triple phosphates,—quinine, iron, and strychnine). On the slightest indication of a disposition to attacks of ague (of which he had several), quinine was given in 10-grain doses twice a day. Under this management, with a liberal diet, he soon improved; the size of the spleen diminished rapidly; in process of time the skin lost its unhealthy colour, his appetite improved; the attacks of ague ceased, albumen disappeared entirely from the urine, and slowly red globules took the place of white. The spleen finally returned to almost its normal limits, and this man, whose career as a soldier seemed on admission at an end, was discharged in very good health.

"Sir James Simpson, Bart., having seen this case and several others from the Mauritius then under treatment in the hospital, advised me to make trial of a new drug, the nitrate of furfurine, a preparation from bran, which this eminent physician had found useful in similar cases. I procured a supply from Messrs. Duncan and Flockhart, of Edinburgh, and used it in this and several other cases of a like kind. It would be absurd after so limited a trial to speak with confidence on the claims of this new medicine. But this was the testimony of all the men to whom it was given, who had no preconceived notions on the subject,—viz., that when taken for a few days it improved appetite and digestion, and pleasantly stimulated the action of the bowels, almost always capriciously irregular in such cases.

I have procured a fresh supply, and mean to give it a more extended trial in cases like this, withholding other remedies.

"Nothing is more common than to find albumen in the urine of patients with enlarged spleens, and their systems charged with malaria; I have ceased to regard this with alarm, provided the urine is at the same time free from casts.

"The albumen almost invariably disappears (as in this case) as the spleen diminishes, and the blood is brought into a more healthy condition."

CANCEROUS AFFECTIONS SUCCESSFULLY TREATED.

DR. E. A. KUNKLER (*Pacific Medical and Surgical Journal*) in an extended article upon this subject, giving several cases which he had treated successfully, draws the following inferences:—1st, Cancerous affections are always the result of irritation, present or past, direct or sympathetic, single or multiple; and no cure can be effected unless the causes, if still present, are ascertained and removed. 2d, Inflammatory action in cancer is the result of irritation; the severity of the first depends upon the intensity of the last; and tonic inflammation will subside with the cessation of the irritation, while atonic inflammation will continue, although the original irritation might have ceased, and consequently atonic inflammation must always be attended to. 3d, Acute inflammation leads to suppuration, chronic inflammation leading to abnormal nutrition and induration of the affected parts, according to the degree of inflammation and tissues involved. 4th, Scirrhus cancer is an aggravated induration by fibrinous deposits, causing obliteration of blood vessels in the affected parts, whereby softening and mortification of these parts are occasioned. 5th, Encephaloid, colloid, and the fungoid forms of cancer are the result of various morbid processes involving different tissues and blood vessels. 6th, The cell formations observed in some carcinomatous affections depend on perverted plasma, in which the cells are floating, from which they imbibe an abnormal nutrition. 7th, The offensive odour in the advanced stage of cancerous affections is the result of the decomposition of the animal tissues, whereby sulphuretted and phosphuretted hydrogen are formed. 8th, The destruction of the tissues in cancer is produced by the effect of these fetid gases, especially by the sulphuretted hydrogen. 9th, To arrest the progress of cancer, the removal of the affected parts is sufficient only when the original irritation has subsided, and there is neither atonic inflammation nor induration in the neighbouring parts; but in all the forms of the disease proceeding from internal irritation, and from atonic inflammation and induration, no permanent cure can be expected unless all the pathological conditions are rectified, and the blood brought back to its normal standard.

Foreign Medical Literature.

QUININE AS AN ANTIPYRETIC.*

THE following remarks on the antipyretic properties of sulphate of quinia are extracted from the "Report of the Medical Department of the Royal Hospital, Christiania, for the year 1867" (*Norsk Magazin for Lægevidenskaben*, xxiii. Bind. 1. Hefte). The author, Dr. Fr. Stabell, says:—"I have nothing further of special interest to mention respecting these 33 cases of typhus, except some experiments which were instituted for the purpose of investigating the effect of single large doses of quinine as an antipyretic.

"This is a subject to which Professor Liebermeister, of Båle, has paid great attention, and he has published on it a long and very profound essay ('*Deutsches Archiv. f. Klinische Medicin*,' third volume, first and sixth parts). He ascribes to quinine a decided and almost invariable temperature-reducing effect; and in proof of this adduces a number of temperature observations. I shall communicate the results of two of the experiments which were

* Translated for the MEDICAL PRESS AND CIRCULAR from the *Norsk Magazine for Lægevidenskaben*, 1869.

made in 1867. They are not so numerous that one can, to any extent, draw a conclusion from them, nor are they intended to do more than to contribute their share towards the corroboration of the experiments which were subsequently made. Quinine was exhibited in doses of gr. xx. or gr. x. in six typhus cases, at several separate periods.

"I shall give a brief outline of the history of the case, with the variations of the temperature and pulse in two of these patients:—

"Karen Kristoffersdatter, aged fifteen, admitted Sept. 11, 1867. She had, fourteen days previously, had shivering, with subsequent nervous symptoms; all the time the motions were regular. On her admission, isolated rose spots were found upon the abdomen.

" 13	101.5	101.8	—	

"From this day the temperature fell gradually, and no more quinine was used. On the 2nd of November she was discharged, convalescent.

"While, then, this patient got, on September 23rd, six grains of sulphate of quinia three times a day, both the morning and evening temperature during the ensuing two days fell about a degree, but afterwards again rose, though she persevered with the same dose of quinine, until it attained its former height. On the 1st of October she takes her three quinine powders at once in the evening, and the following morning the temperature sinks lower than it had been at any time since her admission. This, however, is sufficiently evident, that the tempera-

ture on the evening of the 4th is equally low, although she has not taken quinine. Contingencies such as these should make one cautious in drawing too hasty conclusions. On the evening of October 5th we have a violent rise of temperature, the reason for which is assigned above; but the effect of quinine is not absent on this occasion either, just as three days later, when she got but ten grains only.

"Although these temperature reports demand much time and space, I cannot omit to notice, with some detail, another case, in which the effect of the quinine was so considerable and so constant that here we cannot assert, what we might in other instances be inclined to hold, that this effect is to be attributed either to the operation of chance or to inaccurate observation.

"Mrs. Janette Nilsdatter, aged thirty-one years, was admitted October 1st, 1867, from Sagene (Eriksen's brick manufactory). Eight days before she had had shivering and ordinary symptoms of fever, with constipation. On the abdomen was a scattered eruption, partly consisting of rose spots, partly of petechiae.

"I do not extend this table further, as the later notes possess no special interest. She was discharged convalescent on the 3rd of November. It appears, then, in this case, that while on the evening of the 3rd October, the temperature being 104.9°, the patient got twenty grains of quinine, the result was, that the next morning the temperature was nearly 7½° lower (97.5°), and nearly 5½° lower than it had been the preceding morning. On the 6th October she got twenty grains of quinine, with the effect that the evening temperature was nearly a degree lower than on the preceding or the following evening. Now, this is to be observed, as well in the present as in other cases, that the antipyretic effect of the quinine is more marked when it is seconded by the normal morning remission.

"I may also call attention to the fact that so pronounced an antipyretic effect of quinine as that in the cases mentioned above I have never since seen or found alluded to elsewhere, so that it may certainly be regarded as very exceptional. On the other hand, too, I have seen the quinine to have been altogether without effect; but this also is exceptional. In general, we may with safety venture to say that the effect is tolerably certain, especially when the remedy is given towards evening or in the course of the night. *Liebermeister* is said also to have

found that the longer the disease has lasted, the more striking is the effect. He believes that prognostic significance may be attached to the effect of quinine on the temperature. In a case which threatens to be of great severity the influence of quinine on the temperature is little or nothing, whereas it is considerable in a case which will have a favourable result. It appears to me that in this rests an acknowledgment that the disease is in reality not much influenced by the therapeutic agent in question. Since it fails exactly in the cases where it is most required, and is efficacious only where its exhibition is not called for, the use of quinine is, on the whole, manifestly of but little value. Although we can here, by means of an accurate physical instrument, measure the efficacy of the medicine, and although this, in the present case, is not inconsiderable, we must yet admit that it exercises no specific influence on the progress of the disease. Of the typhus patients who, at the time to which this report refers, took quinine in the way mentioned above, one died. The immediate cause of death in this case was hæmorrhage from the bowels. The patient had twice, in the course of the disease, taken an evening dose of 20 grs., and each time with perceptible influence on the temperature."

So far, Professor Stabell. In the same number of the *Norsk Magazin*, Professor Liebermeister's investigations on this subject are again alluded to in a report on the Treatment of Enteric Fever ("Om Behandlingen af Abdominaltyphus"). The use of quinine in heroic doses is thus spoken of:—

"Earlier experiences had imbued the author (*i.e.*, Liebermeister) with the conviction that the perils of typhus might be to a great extent lessened by an antipyretic treatment. Beside cold water, quinine in large doses had preeminently maintained its antipyretic efficacy.

"Some observations seemed to entitle us to hope that quinine, when given perseveringly and for a long time in repeated doses, might perhaps have a still better effect than when given in single large doses. Experiments were instituted on an extensive scale, but the results were altogether unsatisfactory. The considerable diminution of fever, which, almost without exception, was seen in a short time after the administration of a large dose, was not found; not once was the result the same when some considerable quantity was given in repeated doses as when single large doses were exhibited. No doubt the fever curve seemed to run somewhat lower where the quantities given were not too small. But the strong remissions, which are of obvious advantage to the patients, did not occur. It is also evident that the persistent use of quinine did not exercise any specific influence whatever in cutting short the disease. In consequence, the author, whenever he desired its antipyretic effect, employed full doses (20 or 30 grs., or less, according to circumstances) within as short a time as possible—at the most two hours, and repeated this dose, should the fever return after two days, but never before the lapse of thirty-six hours."

Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

NOVEMBER 22, 1869.

PETER MARSHALL, Esq., President, in the chair.

MR. DE MERIC exhibited a hypertrophied clitoris and nymphæ, which he had excised from a patient. He stated that infiltrations of fibrinous deposits were common, but hypertrophy connected with syphilis rare. He also mentioned a case of elephantiasis, with psoriasis of foot, which yielded to iodide of potassium, &c.

DR. TILBURY FOX objected to the term elephantiasis in these cases. He limited it to true leprosy.

MR. HENRY LEE brought before the Fellows a patient whose hip he had excised three years ago. The lad had perfect motion

of the joint, and walked daily seven or eight miles. He also produced a case of excision of the knee-joint, where the operation had been performed six months. The peculiarity of this case was, that he had left half of the patella, which was ankylosed. Mr. Lee then detailed six unusual cases happening in his practice. Case 1: That of an old lady, ninety years of age, who fractured her hip-bone. Six months afterwards she died, and provisional callus was thrown out sufficient to keep the ends of the bone in apposition. Case 2: That of a syphilitic patient, who lost nearly the whole of the tongue; but the disease was stopped by the use of the calomel bath and the free administration of sarsaparilla. Case 3: Disappearance of testicle in a patient suffering from inguinal hernia, for which the patient wore a truss; on leaving off the truss the testicle descended. Case 4: The patient struck her arm; abscess formed; remained open five months; fibrous ankylosis took place; another abscess formed; elbow-joint excised; unhealthy wound remained; arm amputated; good stump formed, which became very sensitive. After months of suffering the median and ulna nerves were dissected out, the extremities of which were enlarged, forming cartilaginous bulbs. Pain returned after a time. All the nerves were then divided near the armpit; pain unrelieved. The humerus was then removed at glenoid cavity; the wound readily healed, and the patient free from pain. Case 5: Embolism simulating syphilis. An officer was suddenly prostrated; had eruption on skin; pain in bones; one leg extremely swelled, then the other, with pain and redness of skin, but with little œdema; right eye became affected; lost sight; disease unaffected with remedies; echymosed spots beneath conjunctiva; black patch on tunica albuginea; cornea sloughed. Case 6: Double vision with one eye; sees two distinct objects with either eye; and when both eyes are open, by pressing on the globe four objects are seen.

A very interesting discussion followed, in which Drs. Hare, Gibbon, Messrs. Brodhurst, Dunn, Weeden Cooke, Spencer Watson, Gant, Gay, and De Meric took part.

ST. ANDREW'S MEDICAL GRADUATES' ASSOCIATION.

THE PRESIDENT'S ADDRESS.

DR. RICHARDSON, F.R.S., President, delivered the Address on Thursday evening last.

Having thanked his fellow graduates for the position he held, he stated that medical men live to heal, and he was bold to claim for them that, but for them, many now living would be dead. He therefore took as the subject of his address, the "Science of Cure," and proceeded to treat of the obstacles and methods of advancement.

Speaking first of the former, the President said:—The first load we have to cast off is general dogma, and the use of meaningless phrases and conceits, which are allowed too readily to be confounded with principles of science. We have to escape from the fangs of the learned without wisdom, in this effort; for it has happened that individual men have laid chains on us for generations by mere dogmatic and senseless speculation. Allow me to illustrate this truth by an example. In the beginning of last century, there flourished at Halle a learned medical scholar, by the name of Michael Albertus. Michael taught the practice of medicine in the University of Halle, with *clat* unbounded. An industrious man, he left no less than 385 essays behind him, not one, possibly, with a single poor fact; yet all influencing his days, and the days that came, and even the days that are. Full of speculative fancy leading to nothing, and wanting utterly in experimental foundation, our learned Michael took it into his head to divide the process of curing into three great branches, and he was good enough to devote a special essay to the elucidation of each branch. His first essay he named, "De curatione per contraria;" his second, "De curatione per similia;" his third, "De curatione per expectationem." The dogma enunciated in the first of these essays, because it seems to cover the largest view of curative medicine, has been the most orthodox, and in distinction of it, the term Allopathy has been applied. The dogma enunciated in the second of these essays, "De curatione per similia," seized upon by another wilder and more concentrate dogmatist,

than the master, I mean Hahnemann, who was about six years old when Albertus died, and who was trained in the same University, has been converted into a pretended all-curative system, under the name of Homeopathy. The third of these essays, "De curatione per expectationem," seized on by another concentrate dogmatist, has also been converted into a pretended system, under the name, the Expectant Treatment; and has been the delightful resort and resource of all the timid sceptics for many generations. In fine, these three divisions of so-called curative medicine remain as actual systems to the present hour; absolute systems for men to live and practise by; yet all gross and imbecile assumptions, each a curse blighting science, and saying to medicine, You may be a practice, a system, a school, but a true science you shall not be. Now I think the time has come when we should manfully declare ourselves freed, not from one, but from all these dogmas. If a patient come to me with a limb broken and bent, I straighten that limb and place it firmly in its natural, as distinguished from its unnatural, position; but it were insult to tell me that because this is my practice I am an allopathist. If a patient come to me and say, "I have eaten something which makes me faint and inclined to vomit," I will give that patient an emetic, and relieve him of his anxiety; but it were an insult to tell me that because I do this I am an homeopathist. If a patient come to me and say, "I have a sadness of spirit which I cannot overcome," and I see that he has no physical evil, I may decline to prescribe any specific remedy, but may assure him of his safety, and tell him in other words, after Horace:—

"What if thy heaven be overcast,
The dark appearance will not last,
Except a brighter sky;
The god that strings the silver bow,
Awakes sometimes the muses too,
And lays his arrows by."

And if this man, waiting for the brighter sky, as I advise and assure him, does in time see it and recover, I have truly treated him; but it were an insult to tell me that because this is my practice I am a follower of those who carry out the "expectant method."

The other obstacles to advance noticed were, "Individual experience that cannot be made general experience, patent to all who will learn it, and convincing to all;" and thirdly, the "fear of popular criticism and popular demand—in other words, fear of fashion and its caprices."

The President then considered the methods of advancement, and first of all spoke of the necessity that exists for condensation of that which we now partly understand. Having illustrated this by various examples, he continued as follows:—

I could multiply these illustrations to any extent; but enough has been submitted to prove, I trust, the proposition from which I started, that we want an interval to rest from search for new knowledge that we may consolidate the knowledge we actually possess.

I notice, secondly, that in approaching towards a science of cure it is an essential matter to know what are the natural boundaries of cure. When we are practically to say, Here and now our art, our skill, ends? To this question, in my opinion, the answer is that our skill ends only when in the living organism the natural cycle of life is completed. To my minds all diseases which occur between the first and second childhood are simple accidents; accidents as simple and as pure as collision or other physical misadventure; accidents to be avoided or prevented to a major extent, or if incurred, to be cured, if the curer has sufficient time to exert his curative skill. In this boundary, though it may seem limited to minds enthusiastic beyond reason, the practitioner of medicine finds ample scope for the noblest development of his power. To some ultimate fact he must bend, as must every student of natural science. A Newton may march up to the law of gravitation, and show on definite principles that the earth does truly attract all things to itself; but at this point even a Newton must needs stop, feeling that with the discovery of the law the power of the mind given to man finds its natural termination, and that to ask to know more is to assume a desire to take the place of the Supreme will that designs the law. And so the healer, carrying up his research to the limit of the human intellect, may assert laws, but there must stop. Forcing his conclusions beyond this point, he is led into the impossible difficulty of inventing a new nature, of devising a scheme out of his range altogether, by which the evolution of life out

of death shall be superseded by the introduction of perpetual life in the same form of living organism. Absurd problem! Within the natural boundary, then, the healer is safe, and all the extension and grasp of his intellect is occupied with a series of questions, than which none can be nobler, none worthier, the highest intellectual capacity.

I might dwell at this stage on the question of the prevention of the physical accidents with which life is surrounded from its first to its last and natural stage; but I am dealing with cure, not with prevention, and I therefore have to consider the scope and dimensions of cure. In other words, when the physical accident of disease has presented itself to us in any form, how shall we, within the natural limits, endeavour to save from unnatural death?

In studying the question thus proposed, the primary object is to ascertain how far any skill which we may possess is actually demanded as skill to be enforced, as rule of doctrine and of practice. The case is before us: is it a case where the sufferer will recover without any artificial aid; or is it a case where certain well-known and proved artificial assistance will assist recovery; or is it a case where there can be no recovery in the absence of artificial assistance; or is it a case altogether incurable? Unfortunately, up to the present time the natural division of diseases into these groups has received no serious consideration, and so we are apt to mix up skill with no skill, the active with the inert. To those who merely pretend to cure, this unmeaning and confused admixture, in which all is maze and noise, is shelter and satisfaction. In the confusion who shall discover the pretender from the earnest labourer? In this maze the pretender can walk from morning to evening, from year to year, from age to age, and his experience shall be, that of a certain number of sick treated, a certain number shall die, a certain number shall recover; a certain number shall doubt him, and a certain number shall lift him up as the greatest of curers, in whom they have what they call faith; faith, that is, in the man, not in his knowledge as a something that should be known. In this mazy crowd, in sorry truth, every shade of pretence finds its Alsatia. The man who dispenses infinitesimals which is arithmetic is far too weak to encounter; the man who disbelieves out and out, and bows and laughs inwardly, and looks on; all here are one.

But to earnest men this maze can be no shelter, no hiding place. And so I say to them, it is time they were out of it; time they knew the boundaries, the limitations of cure. I will dwell on this topic a moment longer, in an endeavour to open the way to new thought. We shall then, I think, relieve ourselves of much embarrassment if we can at any time come to some common standard of thought on the question whether there be any such distinct process as may be fairly demonstrated natural cure of disease. The *vis medicatrix nature*, what is that? Is it a word or a fact? We dwell upon it as if it were a fact; we dwell upon it as if it were a principle on which we can often rely altogether, and on which we can always rely to some considerable extent. Is this correct belief? In my way of thinking the belief has, in the abstract, no basis whatever; by which I mean that nature goes her own way without putting out any hand to us for our special and particular aid. If nature were a curer *as is* supposed, then all diseases were spontaneously curable, and all other curers than herself were impostors. But nature pursues her way with men as regardless of their infirmities as of their powers: her general course being toward some grand and unknown end in which the individual sinks into his true insignificance by the side of the vastness of her structure, work, design. The physical living being is born, and by the force of birth is launched into space; but from the moment it is on the earth it is under the physical influence of the earth. As when I take a stone and cast it into the air, it moves for a time against gravity, then finds a point in which there is almost balance between the initial velocity and the attraction, and anon begins in gentle curve to fall, until it has fallen and lies, dead; so man, passing through his curve, endowed with initial velocity or motion of life, is making really and always towards the earth. He is weak, the earth is dragging him; he is faint, the earth has drawn him nearer; he dies, the earth takes him to herself. I speak, of course, now only of the physical man.

Having dwelt on various other methods of advancement, the President concluded his address in the following words:—

"I treat, God cures." Thus bold Ambrose Paré, who, said his enemies when he replaced the seething iron by the ligature, "put life upon a thread." 'Twere a sin even for our friends the pioneers to forget so grand an exclamation. I hope they will retain it in their hearts reverently. Not as the outer

confession of their uselessness in this world, but as the inner consciousness that they are the instruments of a Supreme Intelligence, which, drawing nearer and yet nearer to them as they grow—

"Day by day familiar
With his conceptions, act upon his plans,
And form to his the relish of their souls,—

will, in proportion as they are prepared to receive it, fill them for their work with that eternal and celestial light, by which, in the fulness of time, all truths of Nature shall be revealed to the faithful children of Nature.

Literature.

ATTFIELD'S CHEMISTRY.*

IN 1867 Dr. Attfield brought out, under the name of "An Introduction to Pharmaceutical Chemistry," the first edition of the above work. It proved a success. This year the author, on issuing his second edition, has adopted a more ambitious title, and, as may be imagined, the volume has grown in bulk, viz., from 400 to about 600 pages.

We believe that this manual has been already adopted as the class-book by many of the professors in the public schools throughout the United Kingdom. From text books, says the author, having a similar object it differs in three particulars: first, in the exclusion of matter relating to compounds which at present are only of interest to the scientific chemist; secondly, in containing the chemistry of every substance recognized officially or in general practice as a remedial agent; thirdly, in the paragraphs being so cast that the volume may be used as a guide in studying the science experimentally. The author then commences by giving advice to the student as to the method he should pursue in reading for special purposes. He addresses the chemist, *sui generis*, the medical student, and the aspirant to the major and minor pharmaceutical examinations ("pharmaceutical students").

Amongst many of the special features of this book we may mention the following as peculiar to itself and worthy of being particularized:—

The table of elements, with symbols and *derivations of names*, is given most fully.

The care with which everything that may be useful to the student is noted is certainly a special feature of Dr. Attfield's work. In our previous notice of this book we dwelt upon this point, and we cannot refrain from giving another illustration.

"QUANTITVALENCE.—Turning from the *weights* of atoms, their *value* may now be considered; their *quantivalence* (from *quantitas*, quantity, and *valens*, being worth) may be stated. Here, again, hydrogen is conventionally adopted as the standard of comparison. Oxygen in its relation to hydrogen is bivalent (pronounced thus, biv'-a-lent, of double worth, from *bis*, twice, and *valens*); an atom of it will displace two atoms of hydrogen, or combined with the same number, nitrogen is usually trivalent (triv'-a-lent, from *tres* and *valens*), and carbon quad-riv'-a-lent (from *quatuor*, four, or *quater*, four times, and *valens*)," &c.

The questions and exercises given at intervals are almost too difficult for the medical student; but it is always in the power of the teacher to rectify this point.

The insertion of progressive tables of analyses at intervals through the work is a novel idea, well calculated to bring on the practical student in that *art*. A considerable space is devoted to chemical toxicology, to the examination of urine, quantitative analysis, and dialysis.

The Index is anything but a contemptible part of a book, and we once heard of a reviewer who constructed most of his reviews after a perusal of this part of the work. Although we never put it to this use, we hold the opinion that it is a most valuable adjunct to a book of this class; and we have rarely come across a more carefully constructed one than that contained in Dr. Attfield's "Chemistry." The author has made a study of his own book, and produced an elaboration of the first edition which will meet with special favour amongst teachers. In pharmaceutical chemistry applied to the Pharmacopœia we know of no rival. It is therefore particularly suited to the medical student.

* Chemistry, General, Medical, and Pharmaceutical. By J. Attfield, Ph.D., F.C.S., &c. London: J. Van Voorst. 1869.

CURRENT LITERATURE.

THE fifth volume of the "St. Bartholomew's Hospital Reports" opens with a notice of the late Dr. Edwards, who assisted in editing former volumes of the series, and who too soon followed his predecessor, Dr. Jeaffreson, to the grave. The practical essays that follow bear the names of Savory Callender, Paget, Lowe, Tuckwell, Coleman, Gee, Godson, Lloyd Williams, Holmes Coote, Owen Richards, Thomas Smith, Church, Duckworth, and Vernon. The enumeration of these teachers and alumni of St. Bartholomew's is sufficient to show the varied nature of the contents of the volume. The contributions are all too well finished to render it easy to give an account of them, and those who look to such works will prefer to possess them and judge for themselves. Possibly we may be able at a future time to extract some of the more interesting cases, as we did on a former occasion, and thus give those readers who cannot see the Report itself some specimens of its contents.

A third volume of the "Liverpool Medical and Surgical Reports" has appeared. It is edited by Dr. Braidwood and Mr. Harrison, and contains, in addition to the usual essays, the transactions of the two medical societies of Liverpool. It thus presents a succinct account of medical science in Liverpool. The contributors are—Drs. Inman, Braidwood, Wollaston, Turnbull, Ewing Whittle, Lyster, Davidson, De Zouche, and Messrs. Hakes, Harrison, Brown, Hamilton, Banks Walker, and Bickersteth. The Liverpool School is certainly ably represented in this volume.

The second volume of the "Transactions of the Clinical Society" is also out. It contains thirty-six communications, though we are surprised to miss from it more than one of those which we anticipated with the greatest certainty. This omission must surely be an accident, for the Society is scarcely old enough to have degenerated into the cliquism which has done so much to damage others.

Summary of Science.

BY C. R. C. TICHBORNE, F.C.S., M.R.I.A., ETC.

[The Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

SPONGE TENTS.

MR. HOUGH (Ohio) makes these sponges with the aid of alcohol, having noticed that strong alcohol will quickly set the fibres of common sponge after having been moistened.

The sponge is first thoroughly moistened with water and pressed as dry as the strength of the hand will permit, it is then forced into the desired shape by mould or other means, and then immersed in alcohol. If the spirit is sufficiently strong, 90 to 100 per cent., the sponge is immediately set into the given shape, which it retains perfectly after the pressure or mould is removed. It is then hard, firm, and inflexible, and may be trimmed to a sharp point.

HYDRATED SILICATE OF MAGNESIA

Has been used as a substitute for bismuth in epidemic cholera, diarrhoea, &c.

It is prepared by precipitating a warm diluted solution of Epsom salts with a solution of soluble glass entirely free from lead, until it ceases to produce a precipitate. It is then washed and dried. It forms a soft, light, tasteless powder, and is given in five to ten grain doses.

ON THE PREPARATION OF PURE OXYGEN IN THE COLD.

Cosmos gives the following process as being recommended by M. Bœtger:—If we introduce in a flask furnished with a delivery tube a mixture of equal parts of peroxide of lead and peroxide of barium, and add diluted nitric acid, the reaction at once commences. The effervescence is tranquil, and the gas is collected under water. The oxygen made in this manner is said to be very pure.

PRESERVATION OF ANATOMICAL SPECIMENS.

The same number of *Cosmos* recommends the following:—The preparations it is wished to prepare are dissected in water. They are then treated with a saturated alcoholic solution of corrosive sublimate, and then preserved in vessels filled with pure water. It is only necessary to occasionally replace any water lost by evaporation.

ALBUMEN.

Dr. Méhu uses the following mixture for the detection of albumen:—Crystallized carbolic acid, one part by weight; commercial acetic acid, one part; alcohol, 90 per cent., two parts; mix and keep in a bottle. This fluid is intended to detect albumen in urine; to 100 grammes of urine are added 2 c.c. of commercial nitric acid; and next, after thoroughly mixing 10 c.c. of the carbolic acid solution. This reaction is said to be very superior to the use of nitric acid alone.—From Foreign Report of the *Chemical News*.

M. CHEVREUL ON THE METRICAL SYSTEM.

It appears from M. Chevreul's paper that M. Brisson first proposed that the unit of measure should be taken from nature. He read a paper on the 14th April, 1790, entitled, "On the Uniformity of Measures of Length, Capacity, and Strength, and on a new Method of constructing the Toise to be used as a Standard."

The Bishop of Autun had previously proposed, in the National Assembly, that a uniform system of weights and measures should be made compulsory by law throughout the French Kingdom.

The units of the measure of length proposed by M. Brisson was the length of the pendulum beating seconds at the latitude of Paris, which length had been exactly determined by M. de Mairan, and equalled 3 pieds 0 ponce 8 17-30ths lignes, French measure. The Commission preferred the 10,000,000 part of a quarter of the meridian of Paris. The metre was respectively fixed at 3 pieds 11'442 lignes in 1795, and 3 pieds 11'29 lignes. In 1840 M. Puissant found that there was an error in the calculation of the meridian distance of Montgony and Formentera, and he found that the length of the metre should be 3 pieds 11'375 lignes.

ON THE QUANTITATIVE DETERMINATION OF URIC ACID IN URINE.

The Rev. V. Harcourt, in a paper on the solvent treatment of uric acid, states that the usual methods of estimating this acid are not reliable, and gives the following:—A fourth of the urine of twenty-four hours is evaporated to three fluid ounces; it is treated with a mixture of hydrochloric acid and alcohol in equal parts, each being 2.5 per cent. of the urine employed. It is allowed to stand forty-eight hours, drained on a small filter washed with alcohol (methylated spirit), and then with equal parts of acetic acid and water. The colouring matter and phosphates, &c., are thus removed, and the uric acid is of a light colour, and perfectly, though confusedly, crystalline.

The advantages of this method over those heretofore in use are shown in the experiment which follows. In urine having an acidity of 5 grains per pint, the nitric acid method of Dr. Thudichum gave 1.16 grains of impure uric acid. The ordinary hydrochloric acid method gave 5.53 grains; the method above described gave 9.9 grains of uric acid.

CHLOROUS ACID.

Liquid chlorous acid, as described by M. Brandan, has a deep brown colour, and is very fluid. Even below 0° the vapour exerts a considerable pressure. When freshly prepared the fluid boils about half a degree above 0°. If the fluid is suddenly brought to a temperature of about +8 to 10°, it explodes with great violence. It cannot be kept without spontaneous decomposition. The gas given off from this liquid exhibits the well-known greenish-yellow colour of chlorous acid. The specific gravity of the liquefied gas at 0°, referred to water at 4° (the point of greatest density of water), is 1.3298.

IS NITRIC ACID FORMED DURING A THUNDERSTORM?

Mr. Pepper says that when the spark from the great induction coil at the Polytechnic is passed through common air the result is a red colouration when blown against damp litmus paper. In order to ascertain whether the acid product was nitric acid, the "flaming" spark (nine or ten inches in length) was passed through a bottle containing distilled water, from which another tube passed to the air-pump on drawing the air slowly over the spark, and passing the former into the bottle, nitric acid was obtained in large quantities, so much so that it could be detected by the smell and taste as well as by the ordinary tests. The popular notion that nitric acid is always produced during a thunderstorm would, therefore, appear to be correct. Also, it is evident that the purifying influence of a thunderstorm is a popular idea founded on facts.

This coil is one of the largest yet made. The total weight of the great coil is 15 cwt., and that of the ebonite 477 lbs.

The primary wire is made of copper of the highest conductivity, and weighs 145 lbs. The diameter of this wire is 0.0925 of an inch, and the length 3,770 yards. The number of revolutions of the primary wire round the core of soft iron is 6,000, its arrangement being 3, 6, and 12 strands. The secondary wire is 150 miles in length, and weighs 606 lbs. The spark is 12 inches long.

VEGETABLE EXTRACTS FOR CULINARY USE.

M. Berjot has applied for this purpose the ordinary process for preparing vegetable extracts, which he evaporates in vacuo in a similar manner to those made for pharmaceutical use, one gramme of these extracts being sufficient to convert one litre of bouillon into good soup.

ACTION OF NITRIC ACID UPON EXTRACT OF INDIAN HEMP.

Messrs. Bolas and Francis found that when the resinous extract of Indian hemp was treated with nitric acid, sp. gr. 1.32, a violent action, accompanied with a copious evolution of nitrous fumes, took place. When the action had subsided, the flask was heated for five hours in a water bath; the residual resin was again treated with nitric acid, sp. gr. 1.420; the clear acid solutions were then evaporated to dryness on the water bath, the resinous portion remaining in the flask being again treated with nitric acid, and so on until the whole was dissolved. The residua obtained on evaporating these acid solutions were then washed with water and dissolved in spirit, from which it crystallized in long flat prisms. When pure it is white, and gives an alcoholic solution neutral to test paper. It does not contain nitrogen. It gave on combustion numbers agreeing with the formula—

The acid liquors which have deposited "oxy-cannabin" yield on further evaporation a small quantity of an acid substance, which crystallizes in plates.

TORSION AND TRANSFIXION AS A MEANS OF ARRESTING ARTERIAL HEMORRHAGE.

Dr. R. McKinnon suggests (*N. O. Journal of Medicine*) as a means of arresting hemorrhage, the torsion and transfixion of the artery. Let the bleeding vessel be seized with a pair of torsion forceps and twisted until it assumes a cord shape, so that no blood can pass through the twisted portion, then pass a needle from the cutaneous surface, as recommended by Simpson, in acupressure, and instead of passing the needle over the vessel, have it to transfix the twisted artery, and then pass it into the fleshy parts beyond. The twisted artery is thus made secure against untwisting, and if the torsion is maintained no hemorrhage can possibly occur. In as short time as it may be deemed necessary for the needle to remain, they should be removed, when all sources of irritation from staunching instruments are got rid of. The tunnel is then placed in the most favourable condition to heal by first intention.

INCONTINENCE OF URINE.

Dr. F. B. Wood was called to visit a patient, 14 years of age, who had been troubled, from early childhood, with incontinence of urine to such a degree that it was passing from the urethra, almost constantly, night and day. The penis had an elongated prepuce which was firmly adherent to the glans penis. Concluding that this condition was the cause of the trouble, circumcision was performed, and the adhesion broken up. The wound healed rapidly, and the incontinence was entirely relieved. The patient can now retain his urine eight or twelve hours without difficulty.—*Cincinnati Lancet and Observer*.

CARBOLIZED DRY EARTH.

Dr. Derby, of the Boston City Hospital, has of late been treating bad suppurating wounds and severe burns with "carbolyzed" dry earth—one part of carbolic acid to 100 of pulverized kiln-dried earth—with the most satisfactory results. Carbolyzed dry earth, also carbolyzed bran prepared in the same manner, have also been used by the same surgeon for treating cases of compound fracture, with the effect of maintaining the bones in good position, and obviating the offensive odour so common and objectionable in such cases.

REGISTERED FOR TRANSMISSION ABROAD.

THE MEDICAL PRESS AND CIRCULAR is published simultaneously in London, Edinburgh, and Dublin, every Wednesday morning. Price 5d. Stamped 6d.

By Post to Annual Subscribers, £1 2 6

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, DECEMBER 8, 1869.

THE COLLEGE OF PHYSICIANS OF LONDON.

Who is there who will any longer dare to say that discussions are of no use? At the present day, it seems that changes which would, in the 18th or 17th century, have required at least two or three generations to ripen and to be carried are now no sooner well discussed than they are likely to be acted upon. Would any man in his senses have believed, a year or two ago, that the College of Physicians of London would ever take the trouble to think of any measure that would be popular, or likely to be of benefit to the profession at large, and through this means to the public? Well, we have found that in the midst of this seeming coldness, there were yet some warm human hearts beating, and that where we thought there were but dignitaries, there were also to be found men who can think of the interests of the nation they belong to, as well as of their own pockets. The College of Physicians is about to inaugurate great changes. It proposes to set on foot an examination for the whole of England, licensing persons to practise all branches of the healing art, just, indeed, as has long been in vogue in Germany, under the title of Staats-Examen, and in France. In addition to this, however, the College proposes that two other bodies for granting similar licences to practice should be established in Ireland and Scotland. We don't exactly see what would be the use of this threefold division of the licence-granting body. Why not have one body sending delegates to each of the great towns in Britain and Ireland, instead of three? Are the three parts of this kingdom not yet sufficiently welded together by means of railways and telegraphs, to be able to act together in such a simple affair as this? It has long been a fixed article of our faith, that there will never be any of that wide-spread feeling of fraternity which ought to exist among the members of our humanizing profession, until we have one diploma which all must obtain, before being admitted as qualified to hold any of the Government posts, or Poor Law appointments

throughout the land. In acting as it has recently done, the Council of the College of Physicians of London have earned the warmest praise of the whole of our Profession.

Of course it would not be right of us to blink the fact that a small number of able writers are opposed to all granting of degrees or qualifications to practise by any Government. A distinguished and most thoughtful writer in the *Westminster Review* and in the *Medical Mirror* has recently recommended that, instead of adopting the method of State examinations, which Germany and France have so long made use of, we ought rather to advise the State here entirely to withdraw all licences to practise from every one of the corporations at present entitled to grant them. In fact, according to the writer, the public should be left entirely to choose its own medical adviser; and he would, we believe, be inclined to say that any body of men that chose should be allowed to issue a series of certificates calling it a degree in medicine, as is done in the United States, and that the State should not have the privilege of appointing any set of examiners for medical degrees any more than it possesses the power of instituting a set of examiners in law, or in the trades of baker, butcher, or other callings; we don't exactly understand, however, what objection (if any) the writer referred to could make to the State being allowed to examine any candidate anxious to enter the Army Medical Service, or the Poor Law service. Medical officers of the Army and Poor Law are public servants, and ought, of course, to be examined, if possible, by public test. If they passed such an examination, would not that be the same thing as taking a degree? And if these were admissible for public servants, what objection could there be to any person taking this degree and thus being stamped as a person considered fit by the State to hold any of its situations of trust in the medical profession? We are inclined to believe, however, that the writer in the *Westminster Review* would not much cavil at these remarks. What we presume he objects to above all is the fact that, at present, a host of licensing bodies unite in nothing good, but simply in their zeal not to defend the public from bad practice so much as in the persecution of any persons who, however able, may attempt to practise at all, unless having passed through one of the many portals into the profession. We have no hesitation in saying that we agree with him, if he means this, that the principle of *caveat emptor* should hold good for medical men in civil life, as it does for clergymen, for shoemakers, &c. In fact, it is the height of folly for any corporation of men in society to expect that they can be secured in the sole monopoly of any art. If a foolish gentleman prefers calling in an unlicensed person, when he has dislocated his shoulder or contracted syphilis, we don't see why he should not be allowed to suffer for his mistake, provided the person called in had not fraudulently represented that he had taken any certificate. There are, perhaps, some not exceedingly skilful practitioners even in the Profession: and it seems better that we should prove our superior skill, not by prosecutions, but by better practice than that of bone-setters, old women, and other irregular practitioners. But we must say that we entirely concur in the opinion of the College of Physicians, that the time has now come when our licence to practise is amply sufficient. The machinery is ready to our hand. We have the Medical Council. This body may be rendered more efficient by the plan proposed by Dr. Prosser James, and all that would then be required

would be, that a certain number of examiners should hold courts at stated periods in various towns of the kingdom. After these State examinations were passed, which should entitle its holders to practise in public situations all branches of the healing art, there could be no objection, and much good might arise from as many persons as possible joining the various Universities, Colleges of Physicians and Surgeons, which then also might be made more agreeable places than they have hitherto been for their members. Why should the College of Physicians not be a kind of Club for its members, for reading, not only the medical papers, but other newspapers? Some years ago we complained of the miserable accommodation afforded in the College to the members even, and observed that, seeing that the Fellows of the College were merely chosen by an absurd test, joined to the payment of some fifty guineas, it was rather too bad that they should monopolize the library and the snuggest rooms in the house. This selfishness is now about to disappear. The library is to be opened to Members as well as Fellows, and the Licentiate is to be admitted to the lower rooms. For our own part, we wish that the way of becoming a Fellow were a little more dignified transaction than at present. By dignity we mean, of course, that the Fellowship should be given to persons who have passed a superior examination, and shown themselves more learned than the common run of Members. The Fellows of the College of Surgeons are submitted to an examination. We know that they have attended longer at hospitals than the Members; but, with the most ardent inquiries we have made, we confess we have never been able to learn how any Fellow of the College in Trafalgar-square has been appointed. Such things don't suit the end of the 19th century. Change them quickly, brethren, and let us make human life nobler and more worth living. Don't say a thing is to stand merely because it is there, or because it is English. *English* ought to be the best, and the name should not be applied to contemptible farces any longer.

MR. GOSCHEN'S MINUTE.

WE have heard a good deal of late about the hard-heartedness of Guardians of the Poor. Probably much of, or all that has been said may be true enough. At any rate, it is evident that, whenever well-to-do people see a great deal of the poor, they are apt to become callous to their sufferings, and often forgetful of their duty towards them. Mr. Goschen points out that there is a clear distinction between charity and what every poor person has a right to—namely, sufficient shelter and food to keep him from starving. The spirit of the Poor Law of 1834 is as follows:—It has been found by the investigation of that noted Committee which sat upon the question, and which contained the names of Ricardo and many other celebrities among its ranks, that all systems of granting relief to the poor, which do not attach some disagreeable to the relief granted, tend more or less to pauperize and lower the condition of the very class it endeavours to assist. The only way in which true relief can be effectually granted to the poor, it seems, is by taking them into the workhouses, and separating the sexes, so as to render the workhouse life as barren of attractions as possible, without being in any way unwholesome. All out-door relief to able-bodied persons is absolutely prejudicial; and the only exception to

this rule seems to be in the case of medical relief, which seems to be a thing which no poor person would ask for unless unable to work.

Dr. Chalmers, while in Glasgow, long held out against the English Poor Law, even when conducted in the most perfect spirit of impartiality. He alleged as his reason that, whenever the least educated classes were assured of obtaining an existence of however meagre a kind without labour, they would deteriorate, become less independent, and more helpless. And, indeed, it must be confessed that the population of Glasgow were at present in a more deplorable condition than it was when the great divine and economist lived in it.

Nevertheless, if the Poor Law of 1834 were carried out more strictly, and there were not such a set of twaddling pseudo-philanthropists abroad, to write in our daily papers about "treating the poor with charity, and extending the out-door relief so as not to hurt the feelings of the sensitive poor," &c., &c., we must say that we do prefer the idea that the life of none of the citizens of this realm should be abandoned to chance. Plain and sufficient food, shelter, and clothing, may and ought to be assured to us all when in distress; and certainly an adequate supply of pure air is quite an indispensable necessary of life, both in the workhouse and in the infirmary department. But we cannot see why the infirmaries are not under the same management as the workhouses. It is clearly unfair that persons with any means, even when sick, should be allowed to enter a hospital maintained by other less lowly-minded citizens; and hence we suspect that these Highgate and other Poor-law Hospitals may more or less degenerate into asylums for maintaining persons who would not be allowed to enter a workhouse. Charity is a noble thing. Let us have hospitals, by all means, where persons when sick can be admitted if they can show any just claim to the generosity of their fellow-citizens; but it will no longer be charity if every person who is sick has at once, although not destitute, the right to entry into one of these "grand hotels" for the sick, such as that at Highgate. It seems to us that the Poor-law Medical Service of Ireland ought to be a model to us in London. At any rate, we are quite in a difficulty at present as to what to do with our sick poor.

DR. M'DOWEL AND SIR PATRICK DUN'S HOSPITAL, DUBLIN.

THE recent appointment of a Surgeon to Sir Patrick Dun's Hospital, Dublin, in the room of Dr. B. G. M'Dowel, has been for some weeks the subject of much speculation in professional circles. The entire circumstances have been laid before his professional brethren by Dr. M'Dowel, and we are, therefore, entitled to express a judgment on the transaction.

We have endeavoured to remove from Dr. M'Dowel's statement, as far as possible, the character of an *ex parte* defence, which indeed, it scarcely deserves to be called, and have formed our opinion altogether on the correspondence, which is of itself as eloquent as any words of Dr. M'Dowel could make it.

We quote, however, the opening lines of the document, as they are simply statements of fact:—

"Early in the month of October an Official Statement, signed by the Senior Lecturer, appeared in certain of the

morning papers, to the effect that the Board of Trinity College were about to appoint a Surgeon to Sir Patrick Dun's Hospital, in the room of one of the Surgical Staff who 'had retired.' A few days afterwards a document was sent to each of the Demonstrators in the Medical School of Trinity College, and was also published in the papers, stating that on Saturday, the 30th October, the Provost and Board of Senior Fellows of Trinity College would proceed to appoint a Surgeon to Sir Patrick Dun's Hospital, 'in the room of the Professor of Anatomy and Surgery, whose connexion with the hospital had ceased.' It soon, however, became very generally known that the Professor of Anatomy had not retired, nor had his connexion with the hospital voluntarily ceased; but that, in point of fact, he had been summarily dismissed."

From his own narration we learn the circumstances under which Dr. M'Dowel was dismissed. He had been called on Saturday morning to see a patient brought into hospital in consequence of a fall from a scaffolding eight feet high, and, having seen the patient, he did not think that any serious injury had been sustained, in which view, he says, his colleagues concurred. In the evening the patient was worse, and Dr. M'Dowel was sent for, but being absent from home another of the surgeons visited the case; while Dr. M'Dowel, being, as he says, unaware that the case had assumed any serious aspect, did not visit the hospital on Sunday, and, as the patient was attended by the other surgeon, he was not sent for. On Monday he saw the patient, who had then rallied, and continued to do well for several days, when he was seized with meningitis, and died on the tenth day.

For having omitted to visit the hospital on the Sunday, when a case which proved ultimately fatal was in charge, the Board of Governors reported Dr. M'Dowel to the Board of Trinity College, who passed, and acted upon, the following resolution:—

"The Board of Governors of Sir Patrick Dun's Hospital having represented to the Provost and Senior Fellows of Trinity College that the attendance of Dr. M'Dowel at the hospital is irregular and insufficient, it is resolved that the Provost and Senior Fellows will, in compliance with the School of Physic Act, dispense with the delivery of Clinical Lectures by Dr. M'Dowel, and appoint a surgeon to attend the hospital in his place, should the Governors of the hospital consider such a step to be necessary."

Two questions arise in the consideration of these circumstances. In the first place, was Dr. M'Dowel's offence such as to justify so cruel a punishment as that to which he has been subjected? We believe that the entire voice of the Profession will declare that the individual instance of neglect of duty (if it can be so described) was utterly disproportioned to the punishment inflicted.

Sunday visits at hospital are, we imagine, in the absence of urgent calls, almost as much the exception as the rule; and the dismissal of a surgeon for such a cause is, as far as we know, utterly without precedent, and, therefore, a measure of great harshness.

No doubt, the gravity of the cases under treatment, or the habitual repetition of the neglect, would go far to aggravate the offence; and if the patient were dangerously ill, or if disregard of his duty were the habit of Dr. M'Dowel, the Governors and the Board of Trinity College could urge some extenuation of their act.

But neither of these contingencies appear to have occurred, for Dr. M'Dowel declares that neither he nor his colleagues had the least reason to suspect a serious issue of the case, and the fact that for several days before his death no unfavourable symptom existed is a corroboration of the statement.

But the resolution of the Board charges Dr. M'Dowel's attendance as "irregular and insufficient," and their presumption would seem to be that this occasion was but one from many instances of neglect. To this statement Dr. M'Dowel opposes a flat contradiction, and the Governors of Sir Patrick Dun's corroborate him by their acts. He writes:—

"The charge of irregular and insufficient attendance must have been since preferred against me, on what grounds I do not know, and I respectfully request that it will not be assumed to be true until proof is given. On the other hand, I beg to state, in my own defence, that I was on duty at Sir Patrick Dun's Hospital for five months during the medical year just ended. That during the three months that I acted in my turn as clinical surgeon, I was never absent on any one occasion from my clinical duties, nor did I fail to deliver any one clinical lecture; and that during this period I performed several capital operations, and treated an unusual number of severe accidents with uniform success. Subsequently, at the close of the clinical session, I took charge of the hospital during the months of August and September, and my absence on one day formed the subject of the communication between me and the Governors of Sir Patrick Dun's Hospital, to which you refer."

So far there is a contest for veracity between Dr. M'Dowel and the Governors, but, as far as the correspondence informs us, with all the probability on Dr. M'Dowel's side. If their allegation were true, the Governors would, no doubt, be able to quote frequent reprimands administered by them. They do not do so, and the conclusion is obvious that the charge of irregular and insufficient attendance is unsustainable.

There is a second consideration, however, which, supposing Dr. M'Dowel to have been as culpable as the Governors could show him to be, would place them and the Board of Trinity College in an undesirable position.

They took upon themselves to dismiss Dr. M'Dowel without making the least inquiry, or permitting him a word of defence, for over and over again he demanded an investigation, and directly contradicted their statements, without receiving from them the consideration or justice which every gentleman accords to his groom.

Such despotism could not possibly be justified towards anyone, but towards a gentleman of an educated profession and a Professor of Anatomy and Chirurgery in the University of Dublin it is simply insufferable. We recognize in it the spirit which has so frequently violated good taste and diplomatic tact in matters connected with the School of Physic, and which has given so often to the acts of the Board of Trinity College the appearance of overbearing and want of courtesy. We identify it with the half tolerant disregard with which the request of hospital physicians and surgeons of Dublin has been treated, and we warn those who have the responsibility of advising such a line of proceeding, that the day is passed when the Profession was content to endure, and when Universities and Boards were all powerful and all dominant.

AN IMPORTANT DISCOVERY.

M. Maurice Boncherie, of Paris, lately read an interesting paper before the French Academy of Sciences, extolling the injection of a solution of sulphate of copper into wood, to increase the durability of the latter. The best way to perform it is by displacing the sap and then letting the wood dry in the air. To prove his assertion, M. B. exhibited some railway sleepers laid down in 1847, which were found to be in excellent preservation, and harder than common dry wood. The wood owes its excellence to the combination of oxide of copper with the cellulose of the wood.

SCOTLAND.

MEDICO-CHIRURGICAL SOCIETY OF
EDINBURGH.

WEDNESDAY, DECEMBER 1.

Dr. OMOND, President, in the chair.

DR. P. H. WATSON exhibited, 1. A cast of the foot of a child from which he had removed the os calcis and astragalus for disease of these bones. An incision only was necessary on the inner side of the foot, and no care was taken to preserve the periosteum; the result was a serviceable foot with very slight deformity. 2. Characteristic specimen of oxalate of lime calculus, removed from the bladder of a boy aged 17. The symptoms had lasted for years, and had led at one time to a suspicion of disease existing in the rectum. On his admission into hospital Dr. Watson at once suspected the presence of vesical calculus, and by examination was enabled to determine its nature. Owing to this, taken in connection with the undeveloped condition of the patient's urethra, extraction was effected by the lateral operation, in preference to lithotripsy. 3. Specimen of epithelial cancer of the right upper lip, where it was found necessary to excise a portion of the right superior maxillary bone, in order to remove the entire disease. 4. Parts removed in a case of excision of the knee joint.

DR. JOSEPH BELL showed:—1. An exostosis which he had removed from the fibula of a young man. 2. An interesting specimen of fracture and dislocation of the cervical vertebrae, caused by the fall of a heavy sack of flour on the head of a man while asleep. On dissection, four of the cervical vertebrae were found to be fractured without displacement, and the cause of death was due to the dislocation forwards of the left lower articular facet of the fourth cervical vertebrae, allowing of pressure upon the cord. The cord and its membranes were uninjured. Dr. Bell was of opinion that, had traction been employed, as in the case of dislocation of other joints, the man's life might have been saved; and should a case again occur in his practice, he would be inclined, if leave were obtained, to employ means for the reduction of the dislocation.

MR. ANNANDALE showed:—1. Casts of a foot before and after the operation for talipes. 2. Case of medullary cancer of the femur, in which he had amputated at the upper third of the thigh, and after securing the vessels had dissected out the head of the bone. This method he considered preferable to amputating at the hip-joint, as in his view it lessened the risk of fatal shock. 3. Case of malformation of the rectum, in which the anal orifice was a cul-de-sac, of one inch in depth. 4. Fatty tumour which he had removed from the groin of a patient who, he stated, had travelled seven hundred miles to have the operation performed.

DR. ARGYLL ROBERTSON showed an eye which he had removed on account of violent neuralgic pain. The choroid and sclerotic were the seat of great inflammation.

DR. JOSEPH BELL read notes of three cases of recovery from acute pyæmia. The author, after remarking upon the extreme rarity of the recovery from this complication in operative surgery, proceeded to narrate three cases of well-marked acute pyæmia occurring after operation, and all terminating favourably. The principles of treatment consisted in supporting the patients' strength by nourishing diet, milk, and lime-water, eggs, &c., taking care to administer everything warm. Warm drinks, with or without stimulants, seemed to mitigate the severity of the rigors. In one case quinine was given, which, however, had to be discontinued, as it was found to disagree with the patient.

DR. MATTHEWS DUNCAN believed that, had Dr. Bell included those cases of so-called puerperal fever, many of which came under the observation of the obstetrician, he would have found the recoveries from acute pyæmia greater

than he supposed. Puerperal and surgical were simply cases of acute pyæmia. He was always in the habit of combining quinine and iron in the treatment of such cases. The difficulty in cases of recovery was the uncertainty as to the correctness of the diagnosis.

DR. DOUGLAS read a paper on a case of recovery from abscess of lung, occurring in a girl of fifteen. The symptoms consisted of long-continued paroxysms of coughing, intolerably fetid sputa, and extreme prostration. Small opiates and inhalation gave great relief, while the factor was destroyed by a single drop of carbolic acid placed upon the sponge of the conducting tube of the inhaler. The patient was always able to take a considerable amount of nourishment. The author agreed with Stokes, Watson, and others on the infrequency of this disease.

THE PRESIDENT then delivered his valedictory address, which chiefly consisted of a short review of the business which had occupied the attention of the Society during his term of office. Of the members who had died during that period, the list included the names of some of the most popular and accomplished men in the Profession:—Dr. Macaulay, of London; Dr. J. G. M. Burt, Dr. Robert Hamilton, Dr. Seller, Dr. Begbie, and Mr. Archibald Dickson.

The following office-bearers were then elected for the year 1869-70:—

President.—Professor Bennett.

Vice-Presidents.—Prof. Sanders, Dr. Thomas Keith, Dr. Matthews Duncan.

Councillors.—W. S. Carmichael, Esq.; Dr. William Gordon, Dr. John Duncan, Dr. Thomas R. Fraser, Dr. J. D. Brakenridge, Dr. Claud Muirhead, Dr. A. G. Miller, Dr. Angus Macdonald.

Treasurer.—Dr. George W. Balfour.

Secretaries.—Dr. Argyll Robertson, 40 Queen street; Dr. Grainger Stewart, 32 Queen street.

THE Marquis of Bute has given £1,000 to the building fund of the University of Glasgow.

GEORGE OGILVIE, M.D., has been elected President of the Aberdeen Medico-Chirurgical Society.

JOHN LINTON, M.D., F.R.C.P. Ed., has been elected one of the ordinary Physicians of the Royal Hospital for Sick Children, Edinburgh, vice Thomas Grainger Stewart, M.D., F.R.C.P. Ed., resigned; and Dr. T. Kay Gray has been elected an assistant extra physician, vice Linton.

At a meeting of the Fellows of the Royal College of Surgeons, Edinburgh, held on Saturday, December 4, Dr. James Bell Pettigrew, Pathologist to the Royal Infirmary, was elected Curator of their Museum, in the room of Prof. Sanders.

LORD RECTORSHIP OF ABERDEEN UNIVERSITY.—It is understood that, in compliance with the urgent request of a number of the students of Aberdeen University, Mr. Grant Duff, M.P., the present Lord Rector, will yet allow himself to be nominated for re-election. Sir Wm. Stirling-Maxwell, Bart., having agreed to become a candidate, there will thus be a contest. A large committee has, we believe, been appointed to secure the re-election of the present Rector, while Sir William's supporters are also working assiduously in behalf of their candidate. Considerable excitement is manifest among the students. The election takes place on the 24th inst.

PROPOSED SALE OF WATSON'S HOSPITAL TO THE MANAGERS OF THE ROYAL INFIRMARY, EDINBURGH.—Lord Ormidale has issued an interlocutor in the action of suspension and interdict at the instance of Ballantine and

others against the Edinburgh Merchant Company and Governors of George Watson's Hospital. His Lordship passed the note of suspension, but refused *in hoc statu* to pass the interdict. He refrains in the meantime, while the case has not been matured for judgment, from expressing any opinion on the merits of the questions raised by the parties.

Notes on Current Topics.

Mania-a-potu.

It is stated as an interesting fact, in the *Philadelphia Reporter*, by Dr. Henry Yale Smith, that he has never seen a single case of mania-a-potu in the negro race. Dr. Autrey adds to that fact that he has never seen a case of delirium tremens in the Indian race, in twelve years' practice of medicine in Mexico, where three-fourths or more of the entire inhabitants are Indians, and who are much given to drink with excess, and drink the very worst of liquors. This is a fact that attracted his attention very forcibly, as he had met frequently with cases in other races of people. These two important facts have very naturally suggested the question: is only the European race subject to this disease?

Recent Researches on Artificial Tuberculosis.

The November number of the *Edinburgh Medical Journal* opens with a communication on this subject by Dr. J. B. Sanderson, which forcibly suggests to us the old quotation *Palmam qui meruit ferat*. There is, unhappily, in our profession an occasional forgetfulness of the claims of prior or independent investigators which we deeply regret, and Dr. Sanderson seems to have allowed most important facts of the kind to escape his memory. In the paper we have mentioned and which purports to have been read at Leeds, he says:—

"In April 1878, Dr. Wilson Fox and I published for the first time experiments showing that tuberculosis may be produced in animals traumatically. I happened to have precedence as regards the date of publication, but the experiments were made independently and at about the same time. I produced tuberculosis in the guinea-pig by the insertion of setons, Dr. Fox by the insertion of various non-tuberculous products, and also by setons. This result has since been abundantly confirmed by ourselves and by others, especially by Professor Cohnheim, who produced the required injury, not by setons, but by the introduction of a variety of foreign bodies, in themselves harmless, into the peritoneum. In each case a cold abscess was produced around the foreign body as the primary effect, and tuberculosis supervened."

This looks as if the author were anxious to give honour to whom honour is due, but to us it displays either strange ignorance, or, still more, strange carelessness. Putting aside the work of foreigners who first started the subject, let us look at what has been done by Englishmen. A year before the date named the question had occupied the attention of the Pathological Society of London, as our own reports will prove. In April 1867, Mr. Simon stated at that Society that he had produced tuberculosis by inoculation—in fact, he endorsed the views of Villemin. At that meeting Dr. Andrew Clark announced that he too had been engaged in experiments, and that he had produced the same effects by inoculation with non-tuberculous matter. Moreover, he doubted whether the product-

in any of the experiments of Villemin, Simon, himself, and others, were identical with human tubercle.

We have had the curiosity to turn again to the magnificent monograph of Dr. Wilson Fox (revised by us last year), and we find, in page 3, that he renders justice to Dr. Clark in this matter, and thus proves himself too thoughtful or too conscientious to claim more than his due.

We trust, now that we have pointed out the matter, that Dr. Sanderson will agree with us that the true spirit of science requires this feeling of honour to prevail amongst all investigators.

The Archbishop of Canterbury.

It appears that Dr. Tait, on rising on Thursday morning, 18th November, had a convulsive seizure, followed by left hemiplegia. The palsy of the left arm still continues; but the left leg is no longer paralysed. The treatment has been of the stimulating kind now in vogue. He is now residing at Broadstairs. Messrs. Walter and Raven, Mr. Haden, and Dr. Gull, have all been in attendance. The latest telegram gives better hopes of the Archbishop's restoration to health.

Death from Descending a Well.

A WELL-SINKER, at Windlesham, a few days ago was lowered down to his work by his wife and another labourer; but became asphyxiated on getting to a certain depth. Mr. Mason, a courageous nursery gardener, descended, only to meet with a similar fate; and his brother also descended, and became unconscious; but fortunately was hauled up in time to save his life. Of course this points to the danger of descending wells without first ascertaining that a candle will burn, or causing the entry of pure air into the well beforehand. A little knowledge of the elements of physiology, it has been said, is far more useful to men and women than even reading and writing.

Admission of Pauper Patients into Hospitals.

THE authorities of King's College Hospital cannot entertain the proposition made by the Poor-Law Board to take in pauper patients. They believe that they have no more room than is required to accommodate patients sent by subscribers. All of this points to the necessity of the early consideration of the whole system of hospital relief in London. Our own idea is, that there will have to be instituted a certain number of central offices to which all the sick can go and get tickets of admission into the hospitals according to the number of beds vacant. Many cases in subscribers' hospitals are very trivial.

The Proposed Royal Society of Medicine.

THE Meeting of Delegates from the various societies likely to form the Amalgamated Society, was held on the 30th ultimo, when one of the difficulties towards the proposed union was found to be the expense of the Pathological Society's Transactions. It was not known whether the Amalgamated Society's funds would be sufficient to allow of the sum necessary for carrying out the publication of those costly volumes. It is much to be regretted that there could not be some amalgamation, as the ex-

pense of belonging to so many societies is very great, and a little giving and taking would, we imagine, make it by no means impossible to lessen such expenses; but, it must not be concealed that many gentlemen are afraid lest, in joining the Medico-Chirurgical Society, they should get a little into the power of pompous so-called high-class physicians and surgeons, who might wish to keep up the *dignity* which renders the meetings of that Society so very dull.

Lincoln County Hospital Centenary.

A SERMON was preached in favour of this charity on Thursday, 25th ultimo, by the Bishop of Lincoln, in which he showed how the erection of hospitals for the sick was due to Christianity. At the dinner which followed, the health of the "Medical Officers" was responded to by the veteran Alderman Snow, who said he had been 50 years Surgeon to the institution, and by Dr. Mitchinson, who praised the Institution as one which did excellent service, both to the poor and to the Medical Profession.

Unique and Remarkable Case of Extra-Uterine Fœtation.

DR. LECLUYSE gives a remarkable case of this accident. A woman of twenty-eight, with deformed pelvis, was operated on, and delivered by Cæsarean section, August 15, 1866. She again became pregnant and in labour on March 23, 1868. On examination, the fœtus could be felt beneath the abdominal walls; but the pains shortly ceased, and it was determined to postpone the operation of section. In a few days a vaginal discharge of menstrual or bloody character appeared; no motions of the fœtus were felt, and the lower portion of the abdomen formed a kind of sac for the fœtus.

Cæsarean section was now performed with every care, and a seven or eight months fœtus removed, which was well developed, and dead. The placenta was adherent to the intestines. The wound was closed by sutures, save at the lower part, from which the umbilical cord was allowed to depend, as it was not thought possible safely to detach the placenta by reason of its vascularity. On the fifth day the placenta was decomposed, and part of it removed; the patient died on the tenth day. On examination after death, it was found that the intestines bore no imprint of the placental attachment; but, what was most remarkable and interesting, the uterus, about the size of a goose egg, was found in the right iliac fossa held by strong adhesions, and on its anterior aspect, and a little to the left of the mesial line, was the open wound left by the incision made in the former Cæsarian operation. The sides were cicatrized separately, and left a hiatus through which the ovum had escaped, and formed this remarkable and perhaps unique example.

Syphilitic Gummatous Deposit in the Lungs.

At the meeting of the Société Impériale de Chirurgie for the 27th October, M. Depaul exhibited the lungs of a child that died in ten hours after birth, the mother suffering at the time from mucous patches of the mouth and vulva, and papules of the hands. The child died of asphyxia, the result of imperfect dilatation of the air-cells, as the *post-mortem* examination showed that the admission of air was very limited, and that in the pulmonary

parenchyma a number of dense nodules were deposited, which, on microscopic examination, were identical in structure and appearance with the well-known syphilitic gummatous matter. Thus, while in some cases the development is in the shape of deposit in the liver, in others absence of the thymous gland, the occurrence of this form of lung deposit shows that no organ is free from the influence of the poison.

In this Journal we have recorded from time to time cases of gummatous deposit on the heart, and also on the liver, occurring in Mr. Morgan's Clinique at the Westmoreland Hospital, Dublin.

Varicose Dilatation of Lymphatics.

M. TRELAT has recorded a remarkable case of varicose dorsal lymphatics of the penis, which arose as follows:—A healthy man, aged twenty-six, accidentally struck severely the dorsum of the penis against the corner of a table. The contusion was followed by dense œdema of the organ and of the scrotum. Several little tumours formed, with some relief to the pain, and on opening them a jet of fluid appeared, which, both to the naked eye and on microscopic examination, proved to be lymph, showing that a remarkable dilatation of the lymphatic vessels had taken place, tantamount, in fact, to a varicose condition.

Such a condition has been previously noticed by Ricord, Demarquay, and others, and specially commented on in the thesis of M. Binet.

A Displaced Spleen causing Symptoms of Strangulated Inguinal Hernia.

A REMARKABLE case was submitted to the Société D'Anvers by M. Kurns of a woman, aged forty, who was admitted to hospital apparently suffering from strangulated left inguinal hernia, characterized by pain, fecal vomitings, feeble and rapid pulse, &c., and the occurrence of a tumour about the size of the fist in the right iliac region. Vigorous treatment was resorted to, calomel, injections, &c., and even potential cautery, but without success. On *post-mortem* examination, adhesions were found to have formed between the omentum and the intestines, and flakes of pus in several positions. The tumour was found to be the spleen held by pseudo-membranous bands to the abdominal wall, and also to the intestines, which were very much dilated beneath it. The splenic vessels formed a large cord leading to the left hypochondriac region, but the substance of the organ was normal.

This occurrence may aid practitioners in doubtful or difficult hernial cases, and lead to the more frequent use of gastrotomy.

Swedish Lady Doctors.

THE "Carolinska Institute" in Stockholm has expressed its willingness to admit female students to its lectures in the public hall. Instruction in anatomy will be given to ladies separately. Clinical lectures also will be given separately to female students, but the Carolinska Institute requires that those who join this class shall possess the same preparatory knowledge as the male students—viz., a degree of knowledge corresponding to the so-called university certificate of having passed a successful examination in medico-philosophy. In order to facilitate women qualifying themselves for the above class, the indefatigable Dr.

Schach has opened for ladies a higher course of medical instruction (in Stockholm), amongst whom two or three have expressed their desire to study medicine. The University of Stockholm has lately published its programme under an organised system, and intends to receive women students as well as men. After this we suppose that some of the London Hospitals will in a few years be obliged to open their doors to women.

The Latest Mesmeric Feat!

LE PERE HERVIER, Docteur en Sorbonne, &c., proclaims how, in a few minutes, he was thoroughly cured by Mesmer, and triumphantly points out a tree which grows before his door on the boulevards which was magnetized by Mesmer. Several sick persons have been healed by being near the tree. It preserves its leaves longer than any of its neighbours, and in spring is always the first to put them forth!

The Repression of Mendicity.

LAST week a large and influentially attended meeting of the inhabitants of Paddington was held at Westbournehall, Paddington, for the purpose of establishing a committee for the district in connection with the Central Society for Organizing Charitable Relief and Suppressing Mendicity. Sir Francis Sandford, occupied the chair, supported by the leading clergy and parochial authorities of the parish. Resolutions in accordance with the objects of the meeting were adopted.

Surgical Aid Society.

THE annual meeting of this useful charity was held last week at the London Tavern. This is the 7th year of the Society's existence. The Society has relieved 975 men, 1,377 women, and 419 children, from all parts of England, Scotland, and Ireland, 619 of them were relieved last year. Since its establishment no less than 3,211 appliances have been given out by the Society: the most numerous being elastic stockings, leather knee-caps, &c., of which 1,562 were supplied. £587 was spent during the year in surgical appliances, or surgical fees: the annual subscriptions were £455, life subscriptions being £450. The report shows a small balance in the treasurer's hand.

The Parisian Medico-Legal Society.

IN recently concluding its session, this Society appointed certain of its members to investigate, during the vacation, the following questions: Poisoning by croton-oil; the application of photography, drawing, and various processes of mensuration, to legal medicine; the resistance of newly-born children to asphyxia, and tattooing. Messrs. Devergie, Mayet, Mialhe, Raynal, and Roucher, were appointed to investigate experimentally all questions relating to poisoning by phosphorus.

"Sweet Quinine."

THIS article, extensively advertised as an active preparation of the alkaloid quinia, is said to have proven on analysis to be nothing but cinchona mixed with impure powder of liquorice root. Such an imposition on the profession, and, worse than that, on thousands of sick people, deserves the severest condemnation. It is a swindle of the

most aggravated character, and the man who is responsible for it, if the above statement be correct, should not escape the severest penalty of the law.

Insanity in America.

By the census of 1860, it appears that there were 23,999 insane persons in the United States and Territories, at that date, an increase of 8,389 during the previous decade. Probably there are nearly 30,000 insane persons now. In 1860 there were 40 hospitals for the insane in the States and Territories; and more will be reported in the next census.

These 23,999 insane persons are probably members of nearly that number of families; and stand in ties of endearing relationship to many times that number of kindred; all affected, more or less, with the sorrow that dwells in the homes of the insane. Thus, the insane and their sympathising friends must be counted, in America, by hundreds of thousands.

A New Direction for Medical Literature.

EFFETE and musty modesty gives way rapidly in these enlightened days to "philosophic liberalism" and plain-spoken utilitarianism. The most secret facts of our lives are now made subjects of daily discussion in medical periodicals, and it is well that, within proper limits, such matters should receive consideration under conditions in which public decency shall not be offended.

Discussion of such subjects in purely medical circles and for scientific objects is necessary. The publication of them one inch further is abominable in itself, and would be disreputable to our profession. The public cannot gain, and must be demoralised, by sexual disquisitions, and nothing can justify the circulation amongst them of allusions and instructions which for them can have hardly any charm but that of prurieny.

We have read in the *Philadelphia Reporter* a review of a book entitled "The Physical Life of Woman; Advice to the Maiden, Wife, and Mother. By Dr. Napheys, Member of the Philadelphia County Medical Society." Not having been favoured with an inspection of the volume, we quote from the *Reporter* a description of its contents, which have moved the reviewer to expressions of sublime satisfaction and approbation:—

"We welcome Dr. Naphey's book as a timely and beneficial work.

"It is divided into three parts. The first defines the distinction of the sexes, and treats of puberty, its dangers and hygiene, and of love. Under the latter head some sound physiological advice is given on 'choosing a husband,' on the effects of marriage on woman and man, on the intermarriage of relations, on the age of nubility in man and woman, on the dangers of too late and too early nuptials, on divorce, on the best time of year to marry, and so forth.

"The second part is the wife. It commences with some salutary hints under the heading '*the wedding night*,' and devotes a number of pages to such inquiries of universal hygienic interest as, shall man and wife occupy the same room and bed? what kind of bed is most healthful? *the indulgence and restraint of sexual desire*; the dignity and propriety of the sexual instinct; sterility; over-production, and the limitation of offspring; *the production of the sexes at will*; the signs of pregnancy; the prevention and nature of mothers' marks, &c.

"The literary character of the book is deserving of all the praise which we can bestow upon it.

"Before publishing it, the author submitted the advance sheets to several eminent medical gentlemen, who have endorsed it in the highest terms.

"As the book is published 'by subscription only,' it cannot be obtained through booksellers, but it will be sent post-paid, by the publisher, to any address on receipt of the price; and he informs us that orders of ten or more copies will be filled and sent by express at a very liberal discount to physicians who would wish to place it in the hands of their patients, or students who will act as agents. It is selling with singular rapidity already."

If the author has dealt with the subjects which we have italicised in the foregoing extract without "offence to the most sensitive delicacy" he must be indeed the most subtle of writers. But in such discussions elaborate delicacy is almost as suggestive as absolute obscenity; and, in our opinion, no possible involutions of the author's meaning could make such subjects even moderately decent.

We are wont, at our side of the Atlantic, to describe the obscene quackery which pollutes our newspapers in very unequivocal expletives. How shall we phrase our censure of the author who, within the ranks of our own profession, puts forth such abominations in such form that they "can be sent by the publisher post paid, to any address?" What credit shall we accord to the medical journal which notices such lucubration in terms of adulation? and what estimate may we form of the moral status of our profession, where such a work may emanate from an A.M. and M.D., and member of a medical society, be openly approved in a professional periodical, and be offered "at a very liberal discount to physicians who wish to place it in the hands of their patients?"

Cheap Meals for the Poor.

A MEETING was held last week at the Cannon-street Hotel, for the purpose of considering the best means of providing cheap meals for the poor during the winter. The chair was taken by Sir Wm. Tite, who in opening the proceedings, stated that the object was not to promote the sale of any particular kind of meat, but simply to establish depots and cookery-houses, where good and cheap meals might be provided for the working classes, and which depots should be within convenient distances of their places of employment.

Mr. Solly, senior surgeon, St. Thomas's Hospital, bore testimony to the excellence of the fare in Norton Folgate, especially the sausages. As a medical man, he could assure the meeting that the best way to keep the poor free from epidemics was to keep them well-fed. (Hear.) In the great hospitals, the nourishment did more for the patients than the greatest medical skill. (Hear.) The resolution was, like the preceding one, unanimously agreed to.

Sir William Tite, when acknowledging a cordial vote of thanks, observed that a dinner for 1,200 persons, which, he understood, was the number entertained at Lambeth Baths, was a hard test of both food and cookery. They had, *per contra*, the evidence of his friend Mr. Solly, a man who liked good dinners—(a laugh)—and who had been perfectly satisfied at Norton Folgate, especially with the sausages. (Laughter.) They would now set the committee to work, and he was happy to say that they had already nearly £500 in hand—a good beginning.

The meeting then separated.

Royal Medical and Chirurgical Society.

ON Tuesday, Nov. 23rd, there was read at this Society, under the auspices of Mr. John Marshall of University College, a paper by Dr. William Meyer, of Copenhagen, on "Adenoid Vegetations in the Naso-pharyngeal Cavity; their Pathology, Diagnosis, and Treatment." According to the author there exists a certain form of defective speech, often accompanied by imperfect hearing, which is found to be dependent on the presence of exuberant growths of vegetation in certain parts of the naso-pharyngeal cavity. These, he thinks, are occasioned by gland-like vegetations growing beneath the mucous membrane. Symptoms were, the effect on the speech, and flattening of the nostrils, with, in some cases, deafness. The diagnosis is to be made by touch, by means of the forefinger introduced into the cavity. The treatment recommended was to remove the growth by means of a ring-shaped knife, which caused a good deal of bleeding; or, as auxiliary means, the nasal douche, or nitrate of silver, or galvanic cautery applied to the parts. The paper was written in admirable vernacular; but it was a heavy paper, and Mr. Marshall alone gave cases to illustrate what was meant by the author. Of 700 orphans at Haverstock-hill School two presented the characteristic faces, and there was certainly obstruction to the finger behind the soft palate.

Correspondence.

LARGE FAMILIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Though not uninterested in the important debate going on in your columns, I confess to being surprised at the attempts of your correspondents to divert it from a medical into a theological discussion. It appears to me that, in a medical journal, the medical aspects of a question properly find a place, and that differences of religious opinions should never be imported.

Begging the attention of your correspondents to this,

I am, Sir, &c.,

PRACTITIONER.

[We quite agree with our correspondent as to the limits of the discussion. We have been obliged to refuse insertion to several letters on this ground; and the exigencies of our space demand that in future our correspondents must strictly confine themselves to the medical aspects of the questions on which they write.—ED. MED. PRESS & CIRC.]

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having seen so many communications on the subject of large families, and not having noticed that any of them mention what I consider one of the chief sources of this political evil, I beg to introduce it to your notice in a few words.

Our modern mothers seem to have lost a great deal of that love and tenderness for their offspring which used to be displayed in former times by the women suckling their infants with the proper provision that God had given them for the nurture of the tender children. In these days the breasts of a mother seem to be of no use whatever but to afford doubtful signs of pregnancy.

In olden time, wet nurses were only in demand when the mother had died in giving birth to her infant, or by the means of some puerperal disease was forbidden to nurse; but now nothing seems to have milk but the poor peasantry and beasts, as even wet nurses have been dried up by the all-powerful influence of the convenient bottle. The moment an infant awakes from its slumbers and cries out, the nurse runs for "the baby's bottle," and thrusts the india-rubber

teat into the child's mouth, which teat is designed after the shape of its mother's nipple, to deceive the tender mind of the child, which design is, I fancy, a patent humbug, as how could a mind so young require a deception, when it rarely, if ever, felt or saw its mother's nipple? But the latest patentee fancies they require an extra deception, as the precocious infants of the present day won't be satisfied with a nipple alone, they must have a breast, and also have it christened "Mamma" into the bargain, for fear of its refusing it if it was called a bottle. The patentee says, "Its action is the nearest to nature. It is the only one which supplies all the benefits derived from nature itself," &c., &c.

Now, Sir, every medical man and most mothers know that a woman, as an almost universal rule, won't conceive while she is nursing; so if a woman nurses her child properly—that is, for twelve, fifteen, or eighteen months—she can't have children with a less interval between their births than twenty-one, twenty-four, or twenty-seven months, and probably not even so short a time. Whereas, now many of these milkless mothers have a baby nearly every eleven months, which, I think, is too fast to be pleasant.

One of your correspondents, "A Layman," suggests that fathers and mothers should give advice to their marrying sons and daughters. Now, what the fathers are to say to their sons is not in my present province to say; but let the mother's advice to her daughter be, "My dear child, if God gives you children, He has also given you breasts wherewith to suckle them in their tender age; so your duty to your child and society is to eschew the feeding bottle and suckle your infant."

In conclusion, let not patentees or manufacturers think that this letter is a crusade against their productions; it is only a common-sense view of a social evil. Feeding bottles will still be of use when mothers are diseased or removed by death, or when the time comes for the mother to give up nursing; but the present unlimited use of them is prejudicial to mothers, infants, and society at large.

Hoping you will excuse my first trespass on your valuable space, I remain, Sir, yours, &c.,

JUSTITIA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In respect to this important subject, the Paris correspondent of the *Times* gives us information which adds great interest to the discussion going on in your columns, and constitutes the most important contribution to the debate I have yet seen. I send you an extract from the *Times* of last Saturday (December 4), which your correspondents would do well to ponder. Alluding to the lecture of M. Paradol, the Paris correspondent says:—

"He did but give it a passing glance, purposely abstaining from dwelling on a subject which, in some of its bearings, is better adapted to the study of the physician and the physiologist than for discussion in a public lecture. But it comes within the scope of the journalist, and especially of the foreigner whose business it is to observe and report upon the condition and the ways of France and Frenchmen, to examine one branch of that subject of which he is constantly reminded by what he sees and hears, and also not unfrequently by the criminal records of the country. If the population of France increases so slowly that it may, for all practical purposes, be regarded as stationary, this is partly due to the reckless manner in which the children of large classes of the population are abandoned, in their tenderest infancy, to mercenary hands. From Paris especially, but also, in a greater or less degree according to circumstances, from the provincial towns, a stream of newly-born infants constantly flows into the rural districts. The mothers must work; they cannot afford to keep their children at home. More value is attached to their labour than to the welfare and life of the helpless being committed to a stranger's hands. Only the higher classes can indulge in the luxury of a wet nurse at home. Shopkeepers and, generally, the trading and toiling population of the city send their children away. They for the most part do not even see the place whither they are taken, but learn the name of the village or hamlet from a certificate furnished by the mayor of the locality. From time to time they visit their children, but usually at long intervals, because it is often far away, and they have so much to do at home that, between

business and pleasure, they have no time left for their offspring. In France, as you know, women take a more active part in the business of life than in most other countries, and this is especially the case with the trading classes. The tradesman who takes to himself a wife does not regard her merely as an affectionate companion, the mother and nurse of his children, the keeper of his house, but he makes her also the watchful guardian of his mercantile interests, his chief saleswoman, his bookkeeper, and his corresponding clerk. It is the general and almost universal practice in France that the young married woman should be her husband's chief assistant in his business. No mercenary aid, it is argued, can be so valuable, so zealous, or so cheap as hers. The bride steps from the church to the counter, desk, or workroom. When children come they must be got rid of; time is too valuable to be employed in watching and tending them. And so they are despatched into the country to some woman who 'makes it her trade to take nurselings.' The results are obvious enough. The maternal care, which nothing can replace, is wanting, and the mortality is far greater than in countries where a different system prevails. Of course, the poorer the people who thus put out their infants the less they can pay, and the greater is the neglect to which the children are exposed. But even where the payment is liberal the security is small. I will cite an example that came to my own knowledge. A prosperous tradesman, still in the full vigour of life, married a young wife, who was forthwith installed as his head clerk. A child was born, and sent out to nurse in the country. Probably the parents visited it as often as is usually the case, and took the usual precautions, but the child died. Another followed, was also forthwith rusticated, and likewise died. The same thing occurred with a third, fourth, and fifth child. The father, having realized a competency, disposed of his business. A sixth child was born, and reared at home, thrived well, and is still alive and likely to remain so. The parents are healthy people, and it is only fair to suppose that, had the five children had the same chances as the sixth, they would also have lived and flourished. It may be said that this was an exceptional case, but it is no rarity to hear of healthy children dying out at nurse, and, if we may believe the revelations of the French papers, the vigilance of the local authorities is by no means uniformly sufficient to check the malpractices of those child-farming women, who, if they do not actually poison the children, are guilty of neglect and ill-treatment such as almost equally entitles them to be considered murderers. There exists in France an association for the protection of children, but one does not hear much of it, and most assuredly its action can do little to stem the frightful evil. A remedy is hard to suggest for an abuse which has become so rooted in social usages, and yet it is impossible to believe that it will for ever remain uncorrected in a country where M. Paradol lately assured us that 'children are loved with a tenderness often excessive.'"

Hoping you will find room for this extract, which shows that the leading paper has taken up the topic started in your Journal, I am, &c., T. C. D.

Dublin: December 6, 1869.

* * Several letters, from want of space, are unavoidably postponed.

NOTICES TO CORRESPONDENTS.

F.S.A.L.—The discussion on the Multiplication of Mankind is not exactly a medical one, and we cannot, therefore, spare more space for it.

PASS LISTS.—In the lists forwarded to us for publication in our last, from the University of London, the name of Mr. Dukes Clement of St. Thomas's Hospital, was omitted in the Examination for Honours, First class, B.S.

Dr. J. P. LEWIS.—If possible in our next.

"AN M.A., F.R.C.S., ON LARGE FAMILIES."—In as early a number as our space will permit.

A NON-MEMBER is referred to the special article upon the subject of Scholarships in the University of Cambridge, which appears in another column.

MR. J. DAVIES.—The Law is somewhat obscure upon the subject; we will, however, ascertain the best mode of procedure, and let you know.

PROFESSOR MACLEOD'S corrected proof had not reached us at the time of going to press.

DR. BIRCH.—Your letter with the Reviewer's reply, shall appear in our next.

P. C. S. LYDD.—The answer will appear in our next.

The Medical Press & Circular.

Lecture.

THE OBLITERATION OF VARICOSE VEINS. A CLINICAL LECTURE.

By HENRY LEE, Surgeon to St. George's Hospital.

THERE is at present in the hospital a man named R. C., æt. twenty-three, who was admitted eleven months ago, with varicocele of the left side. The left testis had then nearly wasted away, and the dilated veins were painful. He had for two years and a half been under the care of different medical men, and had taken large quantities of medicine without relief.

On the 5th February, two needles were passed between the enlarged veins and the *vas deferens*, and slight pressure was applied to the veins by means of ligatures passed over the ends of the needles. The veins thus compressed by the ligatures were then divided midway between the two needles, by subcutaneous section.

On the day following the operation, the testis of the affected side was very tender; the next day it was swollen; the ligatures over the needles were removed.

Feb. 9th. The needles were removed; the patient was quite easy and free from pain.

Feb. 10th. A considerable amount of thickening had taken place in the scrotum on the left side.

Feb. 14th. The left testis appeared about twice the size that it was when he was admitted.

He now left the hospital and went into the country. Upon his re-admission, eleven months after the operation, the veins which had been then obliterated had not again enlarged, but the left testicle had nearly regained its original and natural size. He had experienced no pain in the part since leaving the hospital, and had remained without inconvenience. Of late, however, he had been suffering from some pain in the right testis; the veins on that side were somewhat enlarged, and the testis he believed had become smaller than formerly. Recognizing the symptoms, as he believed, with which the atrophy of the left testis

commenced, he came to town of his own accord in order to ascertain whether the disease could be averted by the same means as had formerly been adopted on the left side.

I take the foregoing as the text of a lecture because it is one of a large number of cases of enlarged and varicose veins which have been operated upon in this hospital, and an opportunity is now afforded to all those who are interested in the subject, of observing the results of the operation nearly a year after it was performed.

My principal object, however, in recurring to the subject of varicose veins and their obliteration, is to review concisely the causes which have prevented an apparently very simple operation from having been as safely practised in former times as at present; and what I have now to say will apply equally to varicose veins of the leg or of the scrotum.

Sir Everard Home was at one time in the habit of applying a ligature to the *vena saphena major* in cases where the veins of the leg were varicose. In these operations the skin was divided, and a silver needle with ligature was passed under the vein, and the vessel was tied. It was erroneously supposed at that time, as I have already stated, that the lining membrane of a vein when irritated would secrete lymph, just as a serous membrane might, and that the opposite sides of the vessel would thus be glued together.

Mr. Travers, in his very valuable observations on wounds and ligatures of veins, has expressed the idea generally prevalent in his day in the following words:—"The inner membranes of arteries and veins are susceptible of the adhesive inflammation. In veins the inflammation extends from the point irritated towards the heart. The lymph coats the vein like a fringe." The following account, taken from Mr. Travers' work, affords a description of the effects occasionally observed in his day after the operation of placing a ligature upon a vein:—

"I remember about the year 1801, when the operation of tying the saphena major vein was frequently practised for varicose ulcers of the legs, an elderly woman being the subject of this operation, which was performed in Guy's Hospital, a little above, and on the inner side of the knee. Inflammation of the vein followed, and several abscesses

formed in the direction of the vessel, below the ligature, on the inner side of the calf of the leg. It was accompanied with great constitutional disorder; some of the abscesses ulcerated, others advanced with great difficulty to the surface, and the patient died, worn out by excessive irritation. In a second case, that of a man who had drunk hard, two ligatures were made upon the vein, and the vessel was divided between them. In three days the man complained of pain in the course of the vein from the place of its division to the groin: an inflammatory blush appeared upon the leg, extending from the knee to the ankle, and on the succeeding day considerable swelling. The pain above the ligature extended to the bottom of the belly, and the thigh became swollen and tender upon pressure; the constitution sympathized with the local disease, and without the formation of abscesses as in the former case. This man died, as it appeared, from extended inflammation of the vein."

Mr. Hodgson mentions two cases in which the division of the varicose vein terminated fatally; the first on the morning of the fourth day, the second on the seventh or eighth. The same author relates a case from the practice of Mr. Freer, of Birmingham, in which the ligature of a varicose vein was followed by pain in the chest, hurried and laborious breathing, and vomiting of blood four hours after the operation, which symptoms were immediately relieved by the removal of the ligature. The operation was followed by fever and vomiting, and retention of urine, when performed on another varicose vein of the same patient six weeks afterwards, although the ligature was removed immediately after its application; and again by similar symptoms of constitutional disorder, when repeated upon two other veins after an interval of nine weeks, the ligatures being cut away immediately after their application. The fever went further on the latter occasion; the patient was attacked with delirium and severe vomiting on the second day; the symptoms continued on the third and fourth days; on the sixth she was slightly delirious, and her respiration much oppressed. "In this case," says Mr. Hodgson, "the obliteration of the vein was the consequence of the application of a ligature which was immediately removed."

In the fifth volume of the *Edinburgh Medical and Surgical Journal*, Mr. Oldknow, surgeon, of Nottingham, communicates the following important narrative:—

A young man, about twenty-three years of age, of plethoric habit, had been troubled for the last two or three years with painful ulcers about the inner ankle of the right leg, which repeatedly healed, and broke out again, so as to prevent, in a great measure, his attendance to business; he, therefore became desirous, on my representation, of having the saphena vein tied, it being varicose to within a hand's-breadth of the knee. The operation was performed in the following manner. An incision, three-quarters of an inch long, and about one inch and a-half above the distension, was made through the skin, immediately over the vein, and in the direction of its course. The cellular substance was then carefully divided, the vein lying deeper than usual, until its upper surface was completely exposed. A probe armed with a double ligature was passed under the vein, taking care to include nothing with it, it being clearly dissected from the surrounding cellular membrane upwards and downwards as far as the extent of the first incision, and then tied. The portion of the vein between the two ligatures being afterwards cut out, the lips of the wound were brought together by a suture and adhesive plaister, with a view of healing it by the first intention. The patient was then put to bed, and directed to use a cold embrocation. On the second day he took some opening mixture. Third day, the wound was dressed, and appeared wholly united, except when the ligatures came out. The suture was cut out, and a fresh adhesive plaister applied. On this day he complained of pain in the lower part of the limb, that is, from the lowermost ligature, along the vein down the foot, to use his own expression, as if the blood in the veins

were endeavouring to overcome the obstruction caused by the ligature. This sensation was, however, entirely removed by applying a bandage moderately tight, from the toes upwards. On the fifth day there appeared a little erythematous blush about the wound. He had a trifling epistaxis, and I thought proper to take from him sixteen ounces of blood, which was not inflamed; the purging mixture was repeated. Sixth day, complained of a little pain on the inner side of the knee, in the course of the vein; but there was no external inflammation at that part. The lips of the wound began to separate. In the evening he was suddenly seized with a violent rigor, succeeded by a hot fit, and symptoms of great vascular action, and some tendency to delirium. Pulse 130; hard and full, therefore sixteen ounces of blood were taken from the arm; it gave instantaneous relief, and was followed by the sweating stage, which continued several hours, and was succeeded by a state of quietude, soon, however, interrupted by a recurrence of the same train of violent symptoms, at first about once in twenty-four hours, but gradually increasing in frequency, and diminishing in strength, till nature became exhausted; death closing the scene twenty-two days from the operation.

For the first four or five days after the rigor, the wound discharged pretty freely, and by making strong pressure about the knee, a little matter was forced from it. The inflammation crept gradually up the vein, which was evident from its peculiar cord-like feel, and from giving pain on pressure, until it reached the groin, the inferior part getting well as the superior became bad, so that the wound was nearly healed before death, the ligatures having separated about the fourth day. There was no tumefaction of the cellular membrane, no enlargement of the glands in the groin, no superficial inflammation on the thigh. There was, it is true, a slight redness of the skin when the poultice was removed (for the thigh, along the course of the vein, was covered with cold poultice), which entirely vanished on exposure to the air. The medical treatment was strictly antiphlogistic; the patient was repeatedly bled, and with apparent relief every time. Two days, however, previous to his death the vital principle was so exhausted as to need the use of cordials.

Mr. Abernethy believed that it was the ligature that produced the inflammation of the veins in the cases in which such serious mischief followed, and he recommended that the vein should be divided instead of being tied.

Sir Benjamin Brodie adopted Mr. Abernethy's suggestion, and instead of tying the *vena saphena*, cut it across, and applied a compress and bandage. The patient had venous inflammation, attended with very severe typhoid symptoms, and died within four days after the operation. Now, in all the cases to which I have alluded the interior of the divided veins was closed by fibrin only, deposited from the blood. Such a bond of union is constantly liable to give away, and the contents of the veins are then carried into the general circulation. Coagula in veins are in this way, as I have already explained, very readily removed, and if formed from healthy blood, they often appear to produce very little inconvenience to the system. But if these coagula have already begun to undergo morbid changes, if they have already become mixed with other secretions in their neighbourhood, then the most severe symptoms of blood poisoning may be produced. When a vein is simply divided, a certain amount of hæmorrhage necessarily follows, and the blood thus effused may undergo morbid alterations, as it lies at the open mouth of the vessel, and these same diseased actions may be readily communicated to the blood still within the vein, and be thus propagated to every part of the body.

The operation of tying a vein affords no security against such accidents; for in accordance with an observation made by Sir Benjamin Brodie, as the ductus choledochus, or the intestinal canal, will heal after the application of a ligature, without the continuity of the canal being destroyed, so it appears to be with divided veins under certain circumstances. Whenever the circulation through a vein is

thus restored, the coagula of fibrin which temporarily obstructed its canal are, sooner or later, carried into the general circulation.

It appears to us strange, in the present day, that so many centuries had elapsed before a simple mode of securing a bleeding artery was discovered; and it appears almost equally strange that, although surgeons of the highest intellect in the present generation have, in successive years, given their attention to the best mode of operating upon varicose veins, no method should have been adopted by them for effectually closing the vessels during and after the operation. As in former times the actual cautery was used for the purpose of arresting hæmorrhage, so are there still in modern surgery those who prefer the actual cautery or some form of caustic, to the simple mode of closing a vein which I have described in a previous lecture. There has very recently been in this hospital a young woman who had had, I believe, upwards of a dozen sloughs made, on her by the actual cautery, and in a recent number of the *Lancet* the same mode of treatment is advocated by a distinguished surgeon attached to one of our metropolitan hospitals.

Sir Benjamin Brodie some years ago applied the caustic potash over clusters of smaller veins, in order to produce their obliteration, and Mr. Mayo subsequently adopted the same treatment for varicose veins of a larger size. Sir Benjamin Brodie has left us the result of his experience in the following words:—"The application was very painful; the slough took a long time to separate; the sore took a long time to heal, and altogether it was a very tedious process."

Introductory Lecture

DELIVERED AT THE

UNIVERSITY OF GLASGOW,

NOVEMBER 2ND, 1869,

By GEORGE H. B. MACLEOD, M.D., F.R.C.S.E.,

Surgeon to the Royal Infirmary and Lock Hospital; Regius Professor of Surgery.

GENTLEMEN,—I beg to thank you all most sincerely for your kind and encouraging welcome, and I thank in a special manner my learned colleagues and many professional friends who have so greatly honoured me by being present to-day.

I gladly embrace this, the earliest opportunity afforded me, of acknowledging most warmly the generous and hearty sympathy accorded me by the students of the Glasgow School of Medicine during that honourable contest which has ended by my election to the Chair of Surgery in this ancient University.

It will not appear strange to those who have known the aspirations of my professional career, that I should feel deeply thanked for the position I now occupy. I hardly ventured to anticipate, during the currency of the last ten years, that I should again enter, as Teacher, these venerable Halls, where I was educated, and with which so many early and happy days are associated. It is this very day ten years ago that I stood here before to begin a course of Surgical Lectures. Then I had but entered on civil practice, and though I undertook the work assigned to me it was with great hesitation and fear, as I possessed but little experience as a teacher. I replaced one who had ever been to me a warm and constant friend, and who then lay at the point of death. The great reputation as a teacher and practitioner which Dr. Lawrie had so long sustained made my task the more difficult; and if, after his death, I obtained a most generous support when applying for his Chair, it was, I believe, more from the partial kindness of my friends than from any success I could boast of. However, I failed to

secure the succession, and thus made way for one whom you have all learned to admire and respect,—one whose connection with the School has brought it much renown, and whose great merits and distinguished services will, I doubt not, long leave an impress for good on its history.

I cannot on this occasion forget that during the interval which has elapsed since the period I have just referred to, I was indebted to the Andersonian Medical School for the inestimable advantage of obtaining a field for my energies, and for the acquisition of that experience in teaching which is so essential to my future success, and I most gratefully acknowledge the generous support I all along obtained while a member of that School, the friendly intercourse I enjoyed with the Teachers, and the kindness accorded me by the Students. It is in no small measure to my connection with the Andersonian that I attribute the present realisation of my wishes.

Before passing from this short introduction I would further add that if anything could augment the satisfaction I now feel in the prospect before me it is the recollection that I will be allowed to lecture one session, at least, in this old class-room, where I sat as a student, before passing to that palatial residence provided for our "Alma Mater" by the generosity of the nation and the energy of the Senate.

Medicine, Gentlemen, as you know, is a science which aims at preventing, curing, or alleviating disease, and prolonging life by a careful study of the various textures and functions of the human body, the affections to which they are liable, and the remedies which experience has shown to influence them. The practical application of those rules or precepts which observation and experience have approved constitutes the "art" of Medicine. In recent times Medicine has greatly improved her scientific position, and has sought from all the collateral sciences whatever can aid her progress. It is, unfortunately, true that from the nature of her field of inquiry, it is impossible she can ever claim the distinctness and perfection of one of the more exact sciences (as, for example, Mathematics or Chemistry), yet we assert for her an amount of precision and authority greater than that popularly ascribed to her. We do not acknowledge the justness of Voltaire's sarcasm when he likened the physician to a giant with a club laying about him in the dark; or the yet more terrible assertion of Sir A. Cooper, that "Medicine was founded on conjecture and improved by murder." The samespirit, too, is evident in the popular proverb, "The doctor is to be more feared than the disease;" or again (from the Spanish), "Consult the disease but not the physician." Even men of the highest repute among ourselves have not failed to malign her. Dr. James Johnson, long editor of the *Medico-Chirurgical Review*, left this opinion on record:—"I declare as my conscientious conviction, founded on long experience and reflection, that if there were not a single physician, surgeon, apothecary, midwife, chemist, druggist, or drug on the face of the earth, there would be less sickness and less mortality than now prevail;" and Sir W. Hamilton—no mean authority—declared that "Medicine in the hands in which it is vulgarly dispensed is a curse to humanity rather than a blessing." These are strong assertions, and not devoid of truth if Medicine be not studied and practised *scientifically*.

"Medicine," said Lord Bacon, "is a science which has been more professed than laboured, and yet more laboured than advanced, the labour having been more in a circle than in progression; for I find," says he, "much iteration but small addition." This is no time to discuss the reason of this admitted truth, though the germ probably lies in the fact before hinted at—viz., the nature of that subject matter about which Medicine exercises herself. The best commentary on Bacon's charge is probably the celebrated aphorism of Hippocrates, "Life is brief; art is long—experience is fallacious; judgment is difficult." The medical philosopher has to study the most abstruse and obscure, if still the most noble, of all problems—the human body, so wonderfully made, and endowed with such delicate and infinitely varied functions, and moved by

that subtle, mysterious, ungraspable force which vanishes like a shadow when we seek for it.

"Life is brief," so that even the most energetic worker catches but a glimpse of the illimitable ocean of research which lies beyond him. "Art is long," so long that if we work a lifetime at a minute department of the vast whole we cannot exhaust it. "Experience is fallacious," so that what is accepted as true to-day may be and often is rejected and ridiculed to-morrow. And "judgment is so difficult" that few possess that clear, well-balanced mental capacity which is required to give the science any true impulse. It is, doubtless, the want of precision, and, for a time, the apparent confusion, which marks medical studies that so often dishearten and discourage those who pursue them. The student is daily acquiring in the class-room and hospital ward many detached facts and observations which in time supply him with "a respectable chaos of accidental knowledge;" but for long he fails to grasp their connection and relationship to one another, and so his heart sinks within him. But let him persevere and wait. In time the missing link will be found; the omitted facts and observations will come, till at last the mist which enveloped him will roll away, and his mental vision, no longer confined to the narrow tract on which for the moment he stood, will range far and wide over the promised land, and illuminate the path he would pursue with the light of an intelligent comprehension. Let those, then, that falter, and grope, and hesitate, take courage. They suffer only as did those who went before. Let them add fact to fact with care, accuracy, and system, not being repulsed or discouraged by the dryness of the details, and let them wait. Order will come out of confusion, and light out of darkness.

Surgery is that department of Medicine which in its older and stricter sense occupies itself with the manual part (only) of the profession. Celsus thus defines it:—"Surgery is that branch of Physic which informs us how to cure or prevent disorders by the assistance of our hands or instruments, or by the application of external remedies." So long, however, as its province was thus restricted, Surgery filled but an inferior position in public estimation, and it was for long exclusively exercised by slaves, or the servitors of the priests (who became the physicians) in common with the craft of the barber. Its emancipation was painfully slow, and not without much labour; but in our day it occupies no mean place, and its votaries are no servile dependants.

It is customary to assign affections of the external parts of the body to the Surgeon, while the Physician undertakes the charge of the cavities and their viscera; yet it is hardly necessary to say that in actual practice such a distinction is not adhered to. It is plainly impossible to draw a strict line between the departments, as few ailments are so circumscribed in their action as to allow of a distinct classification. If the division I refer to were adhered to, how do skin diseases fall to the care of the Physician, and affections of the bladder and purulent collections in the cavities to the Surgeon? Very many of the diseases which by common consent are placed on either side, so dovetail and overlap, and are so combined, that only in theory can they be discovered. "The Surgeon," said Liston, "must be a Physician, and something more—*i.e.*, he must be able to recognise and combat such general and constitutional conditions as exist and influence the results of the disease or accident he is called on to treat. He must be well instructed in the effects of diathesis, temperament, habits, sex, occupation, and the numerous other influences which make up the factors of the problem to be solved, and he must be able to use with acumen the internal remedies called for. The Surgeon is not, as some would represent him, a mere mechanist—"a superior farrier," ever engaged in torturing and hacking the human body. Unlike the mechanist, he cannot manipulate his materials without taking cognizance of the overruling and pervading vital reactions. His aim, in our day, at least, is chiefly to prevent disease by an

intelligent examination of its causes, and a striving to cure it *without* the knife, an appeal to which he always deeply deploras, but which he assumes when the life or health of the tree demands the removal of a useless or mutilated branch. The true Surgeon looks on the mechanical as a subordinate but yet important part of his craft, and he hopefully anticipates the day when, either by the better enlightenment of the public as to preventive measures, or by the greater perfection of his own art, the operative part of his profession will be greatly curtailed. The Physician, though ignorant of Surgery, may succeed, but he will prove but a sorry Surgeon who knows not the principles and practice of Medicine.

As the body is one and indivisible—likened by Hippocrates to a circle in which each part returns into the other—so, whether we practise Pure Physic or Pure Surgery, we must study and treat the frame as a whole. Our diseases are so commingled and mutually reactive, they receive and give out so many impulses on all sides—being influenced so greatly by the condition of all the organs—and in turn acting so potently in originating or augmenting other changes, that neither Physicians nor Surgeons can close their eyes to all outside of their own special sphere. It was after hopelessly trying, in the wards of a London hospital, to distinguish between the domains of Physic and Surgery, that the Japanese Ambassador is said at last to have exclaimed, thinking that he had seized the idea, "Oh! I see, the medical wards are those in which you kill patients by physio, *not* by cutting off their limbs." Now, it is because of this close interconnection between Physic and Surgery that it is so difficult to arrange a course of Lectures on Surgery without trespassing on the province of other teachers. It were well for all parties, teachers and taught, if the suggestion of Mr. Simon to the General Council were adopted of instituting a short general course of Pathology and Therapeutics which would be preliminary and introductory to all those lectures which touch on such subjects, and so allowing the Professors of Medicine and Surgery to restrict themselves to their own special departments. It must, I think, be conceded that it is to the department of Physic that those reproaches of uncertainty mainly pertain to which reference has been already made. Many internal complaints are so difficult to recognise, and are so little amenable to treatment, that the ability of the science to cope with disease is apt to be called in question. Medical men themselves, judging hastily and rashly, are often led to form extreme views. They frequently claim too much for drugs, and their own powers of discrimination and management; or, having failed to secure such success in the treatment of their cases as their early sanguine hopes anticipated, they have ended by becoming altogether sceptics in Therapeutics. In former times the first opinion was more prevalent than at present. Polypharmacy reigned triumphant, and everything was done or attempted by the pure force of Physic. Men but too often ignored or but little appreciated that silent, ever-active, and all-pervading power, which, veiled under many names, and concealed by many strange conceits and false beliefs, now termed the "vis medicatrix," and then "the physician within the skin," was all the while labouring to restore the dilapidated frame, and to correct what the busy meddler was deranging. The boastful therapist took credit for results solely due to the vital recuperative power of the body itself. "God cures," says the Spanish proverb, "and the doctor pockets the money." In our time a better estimate is made of nature's resources and of our own, and thus, though we interfere less, we may be vastly more useful to the sick. We do not pretend to cure the disease, but we try to remove such obstacles as we can to nature's effort, and we cherish, direct, and control those natural processes by which recovery is accomplished.

Surgery, however, is not so open to strictures of uncertainty and obscurity as Physic. Its field of operation is, for the most part, more patent, its remedies

more capable of being grasped and understood, and its successes more evident and impressive. Richard Wiseman well said long ago, "He that shall duly consider the deplorable misery of mankind, and how much it wanteth relief in such a multitude of instances, must needs acknowledge us to be what antiquity hath long since called us—viz., 'the hands of God.'" Sir B. Brodie has added his testimony as to the satisfactory nature of surgical practice when he says, "The pursuit of what is called Pure Surgery, such as it is in large cities in connection with an hospital and a medical school, is more replete with interest, and on the whole more satisfactory, than any of the other branches into which the medical art is divided."

But, further, the department of Surgery is in our day taught in two great divisions, which are in no way distinct or separable, as some would make us believe, but one and indivisible, though necessarily taught apart. I refer to Systematic and Clinical Surgery. It is difficult to comprehend the obscurity which has been thrown over their respective jurisdictions. When properly taught the one ought to supplement and supply the deficiencies of the other. It is not necessary to depreciate the one in order to commend or exalt the other. *Both* are requisite to the full and satisfactory teaching of Surgery; and fortunate is the instructor who, like myself in this School, has the inestimable advantage of combining both courses and methods of education. Such a union of offices is to my mind essential, and should exist in every School.

Here, in the class-room, it will mainly be my endeavour to inculcate the Principles of Surgery—*i.e.*, those doctrines or generalisations which have been derived from long observation and experience, and which lie at the very foundation of our art. These systematised generalisations being, as it were, the essence of multiplied isolated observations, are in turn applicable in their evolution to numberless individual cases, and he is the best practitioner who intelligently grasps and ably applies such principles. It is the possession of such principles, and the being guided thereby, which raises a medical man from the grade of a paltry trader to the rank of a scientific practitioner.

Again, the very terms used in discussing the science of Surgery must be defined and explained to you in the class-room. The physiology of disease—pathology—must be carefully discussed, and all that is known of that most important department, "the natural history" of surgical disease, must be narrated. It was a true saying of Dr. Grant's that "there is no curing a disease by art without first knowing how it is cured by nature." Beyond this, I must here instruct you in Surgical Therapeutics, in the use of the various mechanical appliances employed in practice, and also in the performance of those operations which we require to have recourse to when other measures fail or are hopeless.

In the clinical course, on the other hand, you will see the practical application and illustration of principles—you can study the living picture and learn to value the colouring which individuality gives to that general delineation or type of the affection described to you in the class-room. By the bedside you will be taught to exercise your senses—your eye, and ear, and touch; how to recognise the origin and progress of the various affections, how to elicit a clear and connected history of the case, and to sift and balance the evidence concerning it. You will also learn how to connect symptoms with pathological changes, and how to modify remedies and appliances to suit special requirements. Thus, then, in one sense, the systematic course may be said to describe the science of Surgery, and the Clinical, the practical part of the subject. Both, I say again, are necessary to you, and if as much as is possible be taught (as it should be) at the bedside, much will yet remain to be learned in the class-room. The half-uttered denunciations of the present day against systematic lectures is due to their bygone abuse, and the former neglect of clinical instruction; but it

must be evident to any candid mind that both methods of instruction are really required, and that if they are made to complement and aid one another they will best accomplish the end in view. It is impossible to dispense with systematic instruction so long as it is thought desirable to systematise and arrange our knowledge, and establish a fitting connection between the different parts of medical education—so long as it is considered necessary that the surgeon should be instructed in the various well-founded views suggested to explain what is obscure and undemonstrable—so long as all the diseases met with by the practitioner, and the different stages and methods of treatment are not presented to the observation of the student in the hospital. Without it no correct judgment can be looked for in the wards, and no intelligent comprehension of what is there described, nor even of the terms used in its explanation.

I have in the foregoing remarks used the term "Clinical instruction," and not lecturing, as the latter phrase is not in any sense applicable to what should constitute such communications, which are often of the highest use when they have reference to some trifling accident or incident occurring in the progress of a case in the hospital wards.

As regards instruction in principles, I would still further add that it is only by the fit understanding of sound principles that sound practice can be attained. "To deliver rules—unqualified and absolute rules"—said John Bell, in his usual nervous style, "into the hands of untaught men, were to put a two-edged sword into the hands of an idiot." If anyone rely on the practical observation of disease *alone* for his alter guidance, and neglect the study of those principles from which practice springs, and which are themselves founded on past experience, he will ever be at a loss. Few cases so resemble one another as to allow of an absolutely similar treatment, as there are in each instance so many individual circumstances to be considered, that no one can safely rely on a recollection of what he has seen done in similar cases to meet the exigencies of practice, while his doing so will debase and degrade his profession. With well established and understood principles, however, to fall back upon, the Surgeon can never be at a loss. Let me tell you what the great Hunter said on this point: "The principles of our art are not less necessary to be understood than the principles of any other science, unless, indeed, the Surgeon should wish to resemble the Chinese philosopher whose knowledge consisted only of facts. In that case the science must remain unimproved until fresh facts arise. In Europe philosophers reason from principles, and thus account for facts before they arise. Too much attention cannot be paid to facts, yet too many facts crowd the memory without advantage any further than they lead us to establish principles. By an acquaintance with principles we learn the causes of disease. Without this knowledge a man cannot be a Surgeon."

(To be continued.)

Original Communications.

NEW PROCESS FOR THE ESTIMATION OF NITRITES IN POTABLE WATER.

NITRATES are very generally found in the well water of towns, and are usually accompanied by nitrites, the base of these salts being either potash, soda, or lime. Different methods have, from time to time, been proposed for estimating the latter salts (the nitrites); but none of them, we believe, have been found satisfactory. At a recent meeting, however, of the Dublin Scientific Club, a process was explained by Dr. Apjohn which would seem to be very easy of execution, and to constitute a complete solution of this chemical problem. Its rest upon the following facts, with which most chemists are acquainted:—

1st. That a solution of a nitrite mixed with one of

iodide of potassium will, when treated with dilute sulphuric acid, yield free iodine.

2nd. That when a nitrate is present instead of a nitrite, and, along with it, iodide of potassium, the addition of sulphuric acid develops no iodine, provided the solution is sufficiently dilute.

3rd. That free iodine can be determined volumetrically with great precision by means of a standard solution of hyposulphite of sodium.

The development of the iodine is the result of the two following reactions:—

Corresponding, then, to every atom of nitrous acid one of iodine is set free, so that if the amount of the latter be known, that of the former is also determined.

As already stated, the amount of free iodine is got by a solution of hyposulphite of sodium, dropped from a volumetric tube into the liquid containing the free iodine until it becomes colourless, in virtue of which the iodine is converted into iodide of sodium, and the hyposulphite of sodium into tetrathionate of sodium.

The volumetric solution of the hyposulphite usually containing one-tenth of an atom of the salt, such quantity will correspond to one-tenth of an atom of iodine, and of course to one-tenth of an atom of nitrous acid, *i.e.*, to 4.7, the integer, 47, being the atomic weight of the acid. As an illustration of this method he mentioned that upon a recent occasion he found that the iodine set free in an experiment required 79.5 measures of the hyposulphite, from which datum and the following proportion:—

$$100 : 79.5 :: 4.7 : x$$

the nitrous acid $x = 3.737$ grains.

ON HASCHISCH IN HYDROPHOBIA.

By Professor POLLI, of Milan.

AMONG the effects resulting from the administration of a large dose of haschisch, I have been struck by the singular impressionability to slight currents of air, and to the glittering of bright bodies; and especially have I noticed the sensation of a species of suffocation, a sensation which seemed to me to be analogous to that which would be produced by a layer of cotton wool adhering to the pharynx. This singular alteration of sensibility inspired me with the idea of making a trial of haschisch in the treatment of hydrophobia—an attempt to treat an incurable and mysterious malady by a no less mysterious remedy.

A man, aged thirty-eight years, was admitted into the Grand Hospital of Milan on May 12, 1860, who had been bitten by a mad dog a month previously, and who was already suffering with all the symptoms of hydrophobia. I determined to treat him solely by haschisch. I employed the brown black extract which I had used in the experiments on myself. He was made to swallow half a gramm (7.7 grains) of it every four hours for five times, so that he took altogether $2\frac{1}{2}$ grammes (38.5 grains) of this extract of Indian hemp. It was cut into small pieces and placed on the tongue; the swallowing of the drug was assisted sometimes by a little sugar, sometimes by a little milk, and sometimes by a little tincture of aniseed. The action of the haschisch taken by the mouth was aided by enemata of an aqueous infusion of coffee, 80 grammes (3.8 ounces) of powdered coffee to a litre (1.76 pint) of water, which was repeated. In a period of little less than twenty-four hours this hydrophobic patient had taken two and a half grammes of extract of Indian hemp, and a litre of infusion of coffee by the rectum. This treatment did not dispel the characteristic phenomenon of horror at the swallowing of water or of any fluid; neither was there freedom of alvine dejections or of emission of urine. The patient remained very constipated, and the urine had to be re-

moved by the catheter. The patient succumbed fifty-six hours after his admission into the hospital; but the evident effect of the haschisch taken was an amiable good humour, a species of gaiety, and of reliance on medical aid; and the cessation of the delirium, the terror, and the convulsive madness which seizes on all hydrophobic persons to such an extent that it is necessary to use physical constraint. Bright light, also, the reflection of shining bodies, currents of air or of the breath, which are insupportable by ordinary hydrophobics, in him produced no disagreeable impression. This patient was left at liberty, that is, without any bonds, lying free on his bed; and this tranquil state lasted forty-eight hours after the commencement of the treatment by haschisch, and was only interrupted by some convulsion or grimace, which slowly became more frequent, and by the menace of suffocation from the foam at the mouth as the mortal symptoms increased, until his death.

The haschisch, without curing the hydrophobia, removed the greatest part of its horrible symptomatology; a result accomplished neither by opium, nor by morphine, nor by daturine. Haschisch, then, is the best palliative or sedative in hydrophobia. It changes a raving, unmanageable, suspicious, aggressive maniac, who bites and who curses, into a poor invalid, content and tranquil, who blesses you.

Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

NOVEMBER 29, 1869.

PETER MARSHALL, Esq., President, in the chair.

MR. SPENCER WATSON read notes of a case of traumatic cataract, remarkable for the presence of symptoms similar to those met with in idiopathic glaucoma, all which symptoms subsided after the removal of the cataract by the linear incision.

MR. E. CALTHROP exhibited an umbilical belt made of black india-rubber. Instead of the central pad, two wedges of wood encircled by an elastic cord are made to act laterally, and close the umbilical opening.

DR. SEMPLE exhibited two specimens of heart disease; the first was large, fat, soft, and flabby, cavities larger than usual, pulmonary and tricuspid valves healthy, but the tricuspid orifice very large; the mitral orifice was large enough to admit four fingers; there were four aortic valves. The points of interest in the case were, that the patient complained of dyspeptic symptoms, the dilated condition of the cavities, great patency of the auricular ventricular orifices, and the four aortic valves. The other specimen was a contrast to the first; there was extensive disease of the aortic valves, almost bony, the mitral orifice very small, and the valves hard and rigid. In this patient a presystolic and systolic murmur at apex was heard at the angle of the scapula, and a systolic and diastolic murmur at the base.

DR. COCKLE read a paper entitled, "Further Notes on Pulsating Tumours of the Neck." This paper was to be considered as a complement to a former one, read before the Society at the close of its last session. Two additional cases of dilatation of the innominate artery were detailed, in one of which, independently of the pulsating tumour in the lowest part of the right side of the neck, aneurism of the upper half of the left carotid artery existed, attended by forcible impulse and remarkable locomotion of the vessel; this was exhibited for examination by the Society. In both cases existed signs of implication of the aorta, but in the latter the murmurs audible over the heart and aorta were attended with certain peculiarities which offered difficulties in the way of differential diagnosis. In adverting to these difficulties, the author was led to offer some remarks upon the subject of cardiac murmurs generally, pointing out the difficulty at times of determining either the precise time during a cardiac revolution at which such murmurs are heard, or the exact seat at which they are generated. The diagnosis of these tumours from some other affection of the chest and neck was

then briefly alluded to, but more especially the points of difference between them and ordinary aneurism of the innominate artery from which they clearly are to be separated. These more especial points of difference were stated to consist in the peculiar intermitting prominence of the tumour, in the constant complication of dilatation in the aorta, in the indefinite duration of the affection, and, according to the author's experience, in its exclusive occurrence in females about the middle age.

DUBLIN UNIVERSITY MEDICO-CHIRURGICAL SOCIETY.

A GENERAL meeting of this Society was held in the Museum Buildings, Trinity College, on Friday evening, 10th inst. The chair was taken at 8 o'clock, College time, by the auditor, Mr. Francis C. Crossli, B.A.

The minutes of the previous meeting having been read and confirmed, Mr. S. Underhill read a paper on "Peritonitis," in which he gave a very interesting account of the symptoms, pathology, and treatment of this disease.

Mr. G. Goode proposed and Mr. Palmer seconded, a vote of thanks to Mr. Underhill.

Mr. J. Brereton then read an account of a case of pyæmia, and also one of compression of the spinal cord from injury, both of which cases were in the City of Dublin Hospital. He also exhibited to the Society a new splint.

Messrs. Palmer, Niven, H. O. Moore and the Auditor then addressed the meeting, which shortly after adjourned.

Foreign Medical Literature.

IMPERFORATE HYMEN.*

BY GOTTFR. CONRADT.

THE following may, perhaps, not be devoid of interest to readers of the Magazine.

On the 26th of last September, a girl aged 18 came under my care. She gave this history of herself. Her parents, workpeople in this town, have always been healthy; she is herself the fifth of seven children; as a little child she had rickets, and, at 13 years of age, scarlatina; but, otherwise, she had enjoyed uninterrupted good health until the completion of her fourteenth year. After this period she began to complain of occasional severe pains in the lower part of the back, without these, however, appearing to have occurred with any fixed periodicity. They have, meanwhile, become steadily worse, and within the past nine months they have reached such a height that she has been obliged to keep her bed for several days at a time. During the last few months there have supervened shooting pains low down in the belly and out into the hips.

About two years ago she rather suddenly experienced a sensation as if something pressed and burst down from the interior towards the external genitals. This feeling has latterly been constantly on the increase, and to it has gradually been added a frequent desire to make water, as well as a difficulty in micturition, which has by degrees increased. The bowels, which formerly were regular, have of late become constipated, and the motions also are passed with difficulty. All these unpleasant symptoms have, within the last eight or ten days, increased to such a degree that she has been obliged to keep to her bed.

The patient is of middle height, well made, with fully developed mammae; but she is rather thin, and has a suffering expression of countenance. Besides the symptoms mentioned above, she complains of languor, headache, want of appetite, and thirst; she is somewhat hot and flushed; the tongue is clean and moist; pulse, 92. There is nothing abnormal to be discovered in the chest; the abdomen is not distended, is soft; the lowest portion of the same, especially just over the symphysis, is found to be tender; the percussion sounds are everywhere resonant, but on making deep pressure immediately behind the pubis a rounded tumour is felt, the closer examination of which is, however, prevented by the tenderness and tension

of the abdominal parietes. On inspection of the external genitals the vulva is seen gaping, the labia majora and minora stand out from each other; on further divaricating them nothing can be seen of the orifice of the vagina, the latter being closed by a smooth, bluish-red, tense membrane, which is pushed forward in the shape of a hemisphere of the size of a small apple. When the patient stands upright the hemispherical swelling becomes larger; when she assumes the horizontal position, smaller. On nearer investigation, fluctuation is perceived through it. The perinaeum is likewise slightly swollen. On introducing a finger into the rectum, the calibre of the intestine is found to be considerably diminished, so that the finger can with difficulty, and only by following the posterior wall, be pushed onward. No uterus can be detected, but as high as the finger can go a fluctuating tumour is felt through the anterior wall of the rectum. On making an examination through the rectum, and by simultaneously pressing on the tumour which projects from the vagina, a still more evident fluctuation is noticed. Through the urethra, which is also pushed upwards, a catheter can, with some difficulty, be drawn inwards to the bladder. By means of it there was passed off about half-a-pint of normal looking urine.

Castor oil was administered as an aperient.

On September 30th an opening was made with a sharp-pointed bistoury about the centre of the fluctuating tumour, after which there slowly oozed out some 32 ounces of a dirty, viscid, inodorous fluid.

October 1st. She has slept well during the night. She is in every respect better,—no pains anywhere. Pulse, 92. The puncture has closed: a slight dilatation at both sides is made with a sound, consequent on which there is again some discharge.

October 4th. She complains of shivering, alternating with heat, headache, thirst, pains in the lowest part of the abdomen, which is moreover tender. The tumour before spoken of is no longer to be felt. Pulse, 108. Bowels regular; during the past 24 hours, slight discharge. She got opium internally, and was ordered a wet stupe with turpentine.

October 5th. Pain and tenderness less. Pulse, 100. Bowels regular.

October 6th. No pain; very slight tenderness; general health good. Pulse, 88. Discharge is thin, somewhat fetid. Washing out with water was practised twice daily through the opening.

October 10th. The discharge ceased. Neither pain nor tenderness. Passing of water and motions regular. Pulse, 72.

As the opening which had been made in the hymen showed an inclination to contract, a sponge-tent, prepared for the purpose, was inserted into it, and was left therein for the night. This was twice repeated, each time with some days' interval. After the sponge-tent was removed, repeated washing out with water was practised. After the third insertion of the sponge-tent the opening was of such a width as to admit of the passage through it of the index-finger, and an exploration was made: the vagina felt wide, without rugæ, the cervix uteri very small, the os open, no tenderness in any part.

October 24th. The menses made their appearance without pains or indisposition.

At the end of November I saw her again. She had a few days before had her menses, after a month's interval, without distress; her appearance and general health were, in every respect, satisfactory. On exploring, the vagina is felt to be more contracted, with a tendency to rugæ. The cervix uteri, moreover, small, the os not so much closed as is usual in virgins.

Malformations of the female organs of generation of such a kind as to become the subject of examination and treatment at the hands of the practical physician, do not, as a general rule, belong to the class of frequently occurring cases; and, as to the one here mentioned, it is so rare that many physicians enjoying an extensive practice have never seen it, while even gynecologists by profession relate but isolated instances of such cases.

In our medical literature there is to be found an observation on "Imperforatio Hymenis," by Brincken, District-Physician of Flekkefjord (Eyr, 1834, Vol. 9, No. 2). In the collected foreign medical literature for the years 1866 and 1867, so far as I have been able to ascertain, hardly a score of communicated cases are to be met with (cf. Virchow's *Jahresbericht* for the present year).

With regard to treatment, it may seem scarcely worth while to mention it, as it must have occurred to everyone that a sufficient incision, and a consequent opening through which

* Translated for the MEDICAL PRESS AND CIRCULAR from the *Nord Magazin for Lægevidenskaben*, xxiii: Bind. 3 Hefte. 1869.

the blood might escape, were all that was in this case required. Several physicians also—for example, Pervin, in Paris; Tuckwell,* of Oxford, and others, have communicated cases which were successfully treated in this way. Yet, the majority recommend great caution in the operation; for instance, West, in his work on the "Diseases of Women," says that we should remember that death has sometimes followed so simple an operation as the incision of an imperforate hymen; Raciborski, in his "Traité de la Menstruation," relates several instances of death from this cause. Marion Sims, in his "Clinical Notes on Uterine Surgery," warns us in the most earnest manner against this apparently so simple incision.

From the experience of these and many other gynecologists it is established, at all events in cases where a very large collection of fluid is found within the closed membrane, that the evacuation of the same should go on as slowly and gradually as possible, in order that the uterus may gain time to contract as its contents flow out. Only a small puncture should therefore be made at first, and subsequently, if required, the opening may be extended. As an example of how dangerous a profuse evacuation is, Sims mentions that a young girl, in whose case there occurred spontaneous rupture of the hymen, and an escape of a large quantity of pent-up menstrual blood, died a few days after. That, however, such a case may sometimes turn out well is proved, apart from the successful operations of Pervin, Tuckwell, and others, by the case communicated by Scanzoni of a girl aged 19, who, after suffering from dysmenorrhœa for two years, on a spontaneous rupture of the hymen occurring suddenly, lost two pounds of blood, and was quite well after it.

Although experience has thus sufficiently proved that the result may be favourable after either mode of proceeding, still, in the operative treatment of imperforate hymen, it will be most advisable to adopt that method which, though far slower and more complicated, is yet, in all probability, the surer.

SCOTLAND.

EDINBURGH.

THE first ordinary meeting of the Royal Society of Edinburgh took place on Monday, the 6th inst. Lord Neaves, one of the vice-presidents, occupied the chair, and delivered the inaugural address, which consisted of a series of biographical sketches of members of the Society who had died during the year. He noticed first the late Dr. Begbie, speaking of him as a friend and as a successful and eminent physician. Among other members noticed were, Allan Dalziel, Dr. Robert Dyce, Professor of Midwifery, Aberdeen; M. Florens, Dr. Graham, Master of the Mint; Principal Forbes, Charles P. F. Martius, Dr. Sellar, Edinburgh; Dr. Wardrop, London; and Professor Penny, Glasgow, of whom Lord Neaves spoke in terms of great admiration.

THE University Court met on Monday, the 6th inst. The following decision was adopted as to the memorial of the Royal College of Surgeons regarding the chair of clinical surgery, upon which parties were heard at last meeting:—"Having duly considered the memorial of the Royal College of Surgeons, proposing an alteration in the system of teaching clinical surgery in the University, and having heard the statements made at last meeting on behalf of the College, and also those made by Professors Spence and Lister, the Court resolve that, in present circumstances, it is not expedient to comply with the prayer of the memorial."

THE acting committee of the managers of the Royal Infirmary, Edinburgh, have issued a circular letter, addressed to the 212 persons who dissented against the proposal to build the new infirmary on the grounds of George Watson's Hospital. In it they call attention to the fact, that

* "On Three Cases of Imperforate Hymen with Retention of the Menstrual Fluid." By H. M. Tuckwell, M.D., Physician to the Radcliffe Infirmary, Oxford, &c.—*Brit. and For. Med. Chir. Review* for July, 1867.—TRANSLATOR.

the public meeting of the subscribers to the building fund, held on the 19th ult., unanimously approved of the course which the managers are adopting, and they respectfully appeal to those opposed to the change of the site, either to recall their dissent or maintain a neutral position. The number of subscribers who have expressed dissent is, as has been stated, 212, representing subscriptions amounting to £4,516 12s., and of these only six or eight have intimated their intention to withdraw their subscriptions. Considering the strong feeling which the discussion of this subject has called forth, it is but reasonable to hope, that now, when the excitement is abating, many, whose names appear in the list of dissentients will withdraw from the position they have assumed. Both parties are actuated by the same desire, namely, to provide suitable accommodation for the sick poor; and while a minority are opposed to the locality selected for the carrying out of this object, it is creditable to them, and calls forth our admiration, that so few have allowed private feeling to influence their pecuniary contribution, and encourages us to believe that hearty co-operation of both parties in the good work will soon prevail.

ABERDEEN.

LORD RECTORSHIP OF THE UNIVERSITY.—The following telegram received in Aberdeen from Mr. Grant Duff, regarding the above vacant office, indicates his willingness to be put in the hands of his friends:—"I am most unwilling to stand against Stirling-Maxwell, but if he is content that his name should be used as the watchword of the Educational obstructives, make any use of me you please. If, however, he gives you satisfactory assurances, you have the fullest authority to withdraw my name at any moment."

GLASGOW.

WE regret to have to record the death of Dr. John Macfarlane, late Professor of the Practice of Medicine in Glasgow University, which took place on the 7th inst. Since his resignation in 1866 of his chair, Dr. Macfarlane has retired from practice. He made many valuable contributions to medical literature, and was greatly esteemed for his geniality, unflinching kindness, and extraordinary sagacity.

ANALYTIC REPORT ON DUBLIN XXX PORTER.

FROM the evidence given before the Parliamentary Committee, and from the published reports extant, it would appear that most of the great porter brewers do not adulterate. The nearest approach to anything of this kind would seem to be in the use of salt, and that only to a moderate degree. It is, however, equally well known that as a rule the porter is not bottled by the brewers, but by men who make bottling a special business; or, what is more frequently the case, it is bought in the wood by the publicans, or retailers, and bottled by them. It is self-evident that the name of a good brewer upon the label is not always a guarantee for the quality of the porter.

The object of the present report is to examine the quality of porter sent out by one of the best known bottlers in Dublin. The bottles were labelled "*Guinness's Dublin Stout, XXX, Brewed for Exportation. Bottled by John Bebe.*"

The samples were examined in the following manner:—*Specific Gravity.*—The porter was exposed for some time with occasional agitation, until the excess of

carbonic gas was eliminated. The gravity was then taken in the ordinary manner, at 14.5 C. It was found to be 1.0195.

Alcohol.—The alcohol was distilled off, and after being made up to the original volume by the addition of distilled water, it was found to have a specific gravity of .9914, which represents 10.9 per cent. of proof spirit as being present in this porter.

Solid Matter (organic and inorganic).—A known quantity of the porter, being evaporated, it was found to contain 4,816 grains to the imperial gallon, nearly half of the organic constituents (4,690 grains) consisted of saccharine matter.

Ash.—On incineration, the ash, or inorganic constituents of the porter, were 126 grains to the gallon. Two points were particularly examined as regards this ash: 1st, the amount of chloride of sodium; the chlorides were under .05 per cent., calculated as Na Cl, therefore it is evident that salt had not been used to any extent, if at all, in the brewing of this porter. 2nd, the ash was perfectly white, which fact indicated that no green copperas had been used for producing the so-called "head;" the ash was rich in phosphates and potash, and otherwise presented the ordinary composition of a cereal ash.

Nitrogenous Matter.—125 grains of the porter, evaporated to dryness, and then burnt with soda lime, were found to contain 2.32 of nitrogen per 1,000 grains, which represents about 1.8 per cent. of albuminous substance, or about 1½ per cent. of the solid matter present.

The acetic acid present was 3.5 grains in 1,000 grains of porter.

It is evident from the above analysis that this bottled porter represents fairly Guinness's XXX stout, a genuine and pure porter containing more than the average quantity of alcohol.

We give the result in a tabular form:—

	Grains per gallon.
(Specific gravity, 1.0195.)	
Alcohol (proof spirit)	7,630
Solid matter	4,816
Saccharine matter	2,300
Ash	126
Albuminous substances (nitrogen, 132 per cent.)	574
Acidity (acetic acid)	245

In speaking of the London porter, one of the most popular lecturers on food says that that beverage (of which there are prodigious quantities consumed) is miserably drugged in the public-houses. Its strength is reduced by water, and its qualities are brought up again by treacle, liquorice, and salt, and various narcotic agents which are added to make up for the loss of alcohol. To such a condition has the porter-drinking population been brought, that they do not know genuine porter when they drink it, and having acquired a taste for its wretched substitute, they reject the unadulterated article.

The specimen examined may be viewed as the type of a pure beverage, and where the desire for fermented malt liquors is indicated by natural taste, few beverages would combine such nutritious value with mild stimulating properties.

In drinking a glass of porter (½ pint) similar to that analysed, the consumer takes in about 1¼ ounce of pabulum (including the alcohol) of easy digestibility. In stimulating property, a glass of Guinness's porter of the above quality is equivalent to one half its bulk of moselle or good claret, a wine-glass of sherry, or an ounce of brandy.

SCHOLARSHIPS AND EXHIBITIONS IN NATURAL SCIENCE AT CAMBRIDGE UNIVERSITY.

THE following is a list of the Scholarships and Exhibitions for proficiency in Natural Science which are likely to be offered at Cambridge during the ensuing year. This list is eminently valuable to *non* but *intending members* of the University, as presenting at once a comprehensive and concise account of the whole, free from the more precise and distributive detail necessarily entered into by the serial notices issued from time to time as vacancies occur.

TRINITY COLLEGE.—One of the value of about £80 per annum. The examination (in Chemistry, Physics, and Physical Geology, including Meteorology, and the elements of Mineralogy), will be in Easter week, and will be open to all Undergraduates of Cambridge and Oxford. Further information may be obtained from the Rev. E. Blose, Tutor of Trinity.

ST. JOHN'S COLLEGE.—One of the value of £50 per annum. The Examination (in Chemistry, Physics, and Physiology, with Geology, Anatomy, and Botany) will take place on the 29th and 30th of April, and will be open to all persons who are not entered at the University, as well as to all who have entered, and not completed one term of residence. In this College, moreover, Natural Science now is made one of the subjects of the regular College Examination of its students at the end of the academical year, in May; and Exhibitions and Foundation Scholarships will, in consequence, be awarded to students who show an amount of knowledge equivalent to that which in Classics or Mathematics usually gains an Exhibition or Scholarship in the College. In short, Natural Science is on the same footing as Classics and Mathematics, both as regards teaching and rewards.

CHRIST'S COLLEGE.—One to four, in value from £30 to £70, according to the number and merits of the candidates, tenable for three-and-a-half years, and three years longer by those who reside during that period at the College. The Examination will be in 1870, and will be open to the Undergraduates of Christ's College, to non-collegiate Undergraduates of Cambridge, to all Undergraduates of Oxford, and any students who are not members of either University. The Candidates may select their own subjects for examination. Besides these there are three other exhibitions, perfectly open, which are distributed annually among the most deserving students of the College.

CLARE COLLEGE.—One of the value of £50 per annum. The Examination (in Chemistry, Chemical Physics, Comparative Anatomy, and Physiology and Geology) will be on March 30, and will be open to students intending to begin residence in October. The candidates must show such acquaintance with Classics and Mathematics as will qualify them to pass the previous examination.

ST. PETER'S COLLEGE.—One of the value of £60 per annum. The Examination (in Chemistry, Botany, and Comparative Anatomy and Physiology) will be in June, and will be open to all students who are not members of the University, or who have not commenced residence in the University.

DOWNING COLLEGE.—One or more, according to the merits of the candidates, of the value of £40 per annum. The Examination (in Chemistry, and Comparative Anatomy and Physiology) will be in March and will be open to all students not members of the University, as well as to all Undergraduates in their first term.

SIDNEY COLLEGE.—Two, of the value of £40 per annum. The Examination (in Heat, Electricity, Chemistry, Geology, Physiology, and Botany) will be in October, and be open to all students who may enter on the College boards before October 1.

Although several subjects for examination are in each

instance given, this rather to afford the option of one or more to the candidates than to induce them to present a superficial notice of several; indeed, it is expressly stated by the authorities of some of the Colleges, that good, clear, knowledge of one or two subjects will be more esteemed than a general knowledge of several.

Candidates, especially those who are not members of the University, will, in most instances, be required to show a fair knowledge of classics and mathematics, such, for example, as would enable them to pass their previous examination.

There is no restriction on the ground of religious denomination in the case of these, or any of the Scholarships or Exhibitions in the Colleges or the University.

Further necessary information may be obtained on application to the Tutors of the respective Colleges.

It may be added that Trinity College will give a Fellowship for Natural Science once, at least, in three years, and that the authorities of most of the Colleges are understood to be willing to award Fellowships for merit in Natural Science equivalent to that for which they are in the habit of giving them for Classics and Mathematics.

REGISTERED FOR TRANSMISSION ABROAD.

MEDICAL REFORM.

THE present position of Medical Reform deserves the serious consideration of every member of the Profession, and is not unworthy the attention of all who take an interest in the general welfare of society. That some change is necessary is admitted by all who think upon the subject. The Medical Council, which was to effect so much, has not given satisfaction; its own members admit the Acts by which it rules ought to be modified. It has demanded more extensive powers, but it has not exercised all those with which it is clothed. Its apologists tell us that it has published a Pharmacopœia and a Register, but the cost at which this has been accomplished is a public scandal. Nor do we admit that the Council was necessary for either. The Colleges of Physicians used to give

us a Pharmacopœia without expense, and the Register does not supplant the Directory issued by private enterprise. Education is yet a moot question, and expensive inquiries are still going on. The Profession is robbed and the public imposed upon by unregistered persons. The corporations continue their opposition to justice, their competition downwards, their petty rivalries. Obstructions flourish—learning languishes. Yet we are paying thousands yearly for a Council which was to have been representative, but has refused to claim its birthright. What is the remedy? All true reformers have insisted that the Council should be a representative body. As such it might safely be intrusted with the whole control of the Profession. Some reformers, amongst whom Dr. Andrew Wood is conspicuous for his zeal, would create new constituencies, and have a certain number of Councillors elected by the registered practitioners residing in the three Kingdoms. Others, and, no doubt, a large majority, prefer the simpler plan originated by Dr. Prosser James, and frequently supported in this Journal. He would merely extend the franchise of the corporations, so that every Member, Licentiate, or Fellow of a College, and every Graduate of a University, should have a vote in the election of the Member of Council chosen by that body. This simple act of justice would transform the Council into a truly representative institution—a Medical Parliament of which we might be proud, and in which the public would have confidence.

The relative popularity of these two plans of reform was well illustrated at the meeting of the British Medical Association at Leeds. The ruling powers of that powerful Association, who usually carry everything before them, urged upon their members the former plan which they had for months been pushing with all their influence. Yet on Professor Haughton proposing the latter plan, it was carried, in spite of all official pressure, by an overwhelming majority of the assembled members. The next day, indeed, the managers contrived, in a much smaller meeting, to pass a resolution that Professor Haughton's amendment need not be insisted on in communications with the Government. It is but right, however, that everyone should know that the Association, in its largest meeting, unhesitatingly approved the plan of Dr. Prosser James, a scheme that has obtained the sanction of thousands of other practitioners, and that leading statesmen have declared the original Act of 1858 was intended to introduce. Why is it not now in operation? We are bound to reply solely because the Medical Council has neglected its duty. In a letter addressed to the President, read at the opening meeting of last Session (see report in MEDICAL PRESS AND CIRCULAR), Dr. Prosser James made a final appeal to that body. He asked it to recommend the several Colleges and Universities to extend their franchise in the election of its members. We know that six members of the Council were in favour of the suggestion, and yet they suffered it to be buried in a committee. By this one act the Council proved itself in discord with the Profession, and unworthy of confidence. But for this self-complacency and obstinacy we might never have heard the cry of “disestablish and disendow” it, which is now being raised. If the Council persist in being a mere petty oligarchy, what interest has any one in it? Why should any one resist the sentence “Cut it down; why cumbereth it the ground?” And this sentence, be it understood, has been pronounced by a powerful party.

Each of the corporations of which it is composed seem likely to be shortly engaged in a struggle for existence, and what will then become of this Council, which has proved itself too weak to control the bodies over which it was placed, too thoroughly imbued with their spirit for independent action, too divided to be able to amend its own constitution, too self-opinionated to adopt the reforms proposed by those outside itself? A house thus divided against itself cannot stand, and the Council may, by its perversity, drag the whole Profession down in its fall.

That it is in imminent danger no one need any longer be ignorant. We have already mentioned the suggestion that has been mooted in some quarters to abolish the Council, and institute a small body of Crown-appointed nominees to govern the Profession. In such a case, farewell to all hope of self-government. The Profession would at once sink in the estimation of all honourable men, and might, henceforth, be abandoned as a calling which had no dignity. The proposer of such a scheme should be apprised that 20,000 professional men will not suffer their rights to be thus summarily taken away, and any member of the Profession who supported it should be ostracised by every one of his brethren. No! a thousand times rather the halting, weak Council we have, with its capacity of being easily transformed into a noble medical parliament, than such an abandonment to the tender mercies of a Government bureau.

There are two notices on the books of the House of Commons. The one simply to enforce on the Council the gentle measure of reform which Dr. James asked it to adopt. The other, by Sir John Gray, who has taken up the question in earnest, is to introduce a Bill of which, we believe, that reform will form a part. We sincerely hope the Profession will not wait until too late before it unequivocally expresses its judgment. Procrastination is dangerous. As time wears on plans are being matured, and a surprise may in reality be effected. The medical Members of Parliament should not be left in the dark, and others should be made to feel how influential a section of any constituency the professional men may be. At any rate we must speak out, and denounce the monstrous notion of destroying our chance of self-government by subjecting us to a bureau of Government nominees. We cannot believe that a Liberal Government can be induced to support a scheme so manifestly opposed to all the traditions of its party; nor do we imagine the greatest admirers of centralisation would wish to extend it to a learned Profession, which has always occupied itself with advancing the interests of mankind, and the only fault of which is its patient endurance of the many disadvantages under which it labours.

THE ALLIED UNIVERSITIES' CLUB.

THIS Journal numbers amongst its readers a large proportion of University graduates, so that the many subjects that interest University men as such are naturally discussed in our columns. That they have not been neglected by us is sufficiently obvious to all who have been accustomed to take up our paper. Oxford, Cambridge, Dublin, London, the Scotch Universities—all in turn have some great question at issue, and each is noticed by us as it comes forward. There are, too, many points in which all the Universities have an equal or a common interest, and others which embrace every seat of learning throughout the world. These larger questions have less chance of discussion than

the smaller ones, but are in many instances of the highest importance. It would be well were they to obtain more general recognition. We are led into these remarks by the formation of the Allied Universities' Club, which offers a sort of centre around which the alumni of all Universities may rally, where they may meet and discuss the questions that concern them, and where they may cultivate that social intercourse with each other which it is not easy to attain elsewhere.

London contains worthy representatives of all the British, and many foreign, Universities—men, too, many of them, who would be glad to meet the graduates of sister seats of learning, and talk over what concerns each—men who can appreciate the idea of a Club of educated gentlemen, and who will be glad to join it. A Club is distinct from an Association, or we should at once be told that there is no room for any new organization. What with societies, associations, unions, and here and there a mis-named Club, there is plenty of opportunity for discussion of certain set questions. But this is a very different thing from the intercourse of a real Club. We think the Allied Universities' Club an excellent idea, and sincerely wish it success. This it ought to attain, as we observe it has already secured the adhesion of Graduates in Divinity, Medicine, Arts, and Law. It will, therefore, not belong to any one profession, but include all. As our Profession is not a rich one, it may be worth while to mention that the first list of names is not yet filled up; but that as soon as it is, according to the usual custom in such cases, the entrance fee will be considerably increased. The Allied Universities' Club is started on the proprietary principle, so that individual members incur no liability beyond their subscriptions (£5 5s. per annum). We have read over the rules, and find nothing in them to which to object. The Club-house is, to our mind, one of the best that could have been selected—12 Grafton street, W. The rooms have a full view of Albemarle street and St. James's street, down to Marlborough House, and in the season cannot fail to be appreciated.

MR. GOSCHEN AND THE HOLBORN UNION.

Quid leges sine moribus? Pauperism in the metropolis, say the daily journals, continues to increase. In the fourth week of November 144,788 persons were receiving parochial relief, in the proportion of 36,265 indoor paupers, and 108,523 outdoor. The total number was more by 3,752 than the figures in the corresponding period of last year.

What are we to do with all these poor people? Are they to be considered as merely acute cases of distress, or shall we be likely to have as great a number of indigent persons on the workhouse lists for some years to come, or, perhaps, even more? Such are the questions we ask ourselves as we glance at the figures above quoted. There is, too, a question of great importance in addition to those we have put, and that is: has the system of workhouse relief broken down, as many say, and does it require remodelling to suit the altered circumstances of our time? It would seem that the Guardians of Holborn Union think that we must make great changes in the Act of 1834, since, in a Minute, apparently drawn up by Dr. Stallard, they have recently expressed their inability to comply with the requirements of that Act. They say, indeed, that they agree entirely with the general principles of the Act, but object to Mr. Goschen's recent letter, which professes to explain

its clauses, inasmuch as they find that he has not entered sufficiently into the details of the subject. Mr. Goschen observes that the Guardians ought to confine their efforts to the relief of the destitute, and that they should not at all give relief in aid of wages, if possible. The Guardians further remark that, with the present state of destitution staring them in the face, the refusal on their part to give relief out of doors would lead to many cases of starvation. Of 6,374 persons recently relieved by them out of doors, the weekly sum of 1s. 2½d. was all that was, on an average, bestowed, and in most of the cases where this pittance was granted the persons were of the class legally entitled to it, namely, those suffering under acute diseases. If adequate relief were granted to all those aided, the rates would be enormously increased, they observe. The following case is cited to explain what they mean:—A tailor breaks his arm. He has a wife and five children, supported by him when in ordinary health. The man is now a patient in St. Bartholomew's Hospital, and the Guardians have ordered his family 5s. and five loaves weekly. This is, we may remark, a distinct infraction of the law, and, probably, an action at law lies against the Guardians of the Holborn Union, if any of the ratepayers choose to bring one, based on this case which they themselves have cited. The Guardians think it clearly unwise to order the man and his family into the workhouse; but we want to know what business the Guardians have to assert their views of things in opposition to the law, which was constructed by far abler men than any of them can be expected to be. For example, Dr. Stallard's views, put forward in a pamphlet last year, would, if acted upon, tend to pauperize the whole country; and, surely, we have enough pauperism already, without running into new strata of the working classes. The Guardians, indeed, know well that the 5s. and five loaves are not sufficient for the family, so they express their opinion that they will "work the neighbouring charities" to obtain a supplement to this inadequate relief.

Surely the Guardians would be doing their duty much more certainly if they would either take in this unfortunate family, or, if not, if they would allow them to "work the neighbouring charities" for the 5s. and the five loaves, in addition to the other charitable doles they already "work" for. Of course, if the pauperism of the metropolis at present resembles in any way that of the cotton famine, there ought to be a cordial co-operation between the Poor-law and charitable agencies; but we don't for a moment believe that this is the case in London at present. There is nothing peculiarly exceptional in the case of the metropolis which should so destroy all the care which the Poor-law Guardians are bound to take; but they do not injure the poor more than they benefit them by their mode of relief, except, indeed, the absurd way in which the poorest parishes are compelled to relieve all the poor of London.

"It is illegal to administer relief so long as a person is in employment and wages are earned, even though such wages may be sufficient. The Poor-law authorities ought to hold aloof, and refuse to supplement the receipts of the family, actually offering, in preference, to take upon themselves the entire cost of their maintenance." Such is the language of the Act. And yet the Guardians, with their united wisdom, think that they know better than this. According to their reply, the language of the statute is indefinite, and it is even admitted that, "in the case of widows with families, where it is manifestly impossible that the earnings of the woman can support the family,

the rule is frequently departed from." It appears, then, the case of widows is such a large one that it puts the statute to nought. Well! we don't see what right the Guardians have to break the law so constantly in favour of widows. It appears to us that when a widow and family are unable to earn their living, they ought, in almost every case, to be taken into the workhouse. The Guardians say it would be impossible to find workhouse accommodation for 20,000 widows in the metropolis, with their 60,000 children. Foolish Guardians! Do they not see that women are not mere imbeciles, and that it is this very conduct of theirs which causes women of the poorer classes to be so improvident in their married life, and to breed so fast as they do? Take them into the workhouse in all cases, and you will find that the supply of widows with three children will soon fall off! The Poor-law Board observes admirably, through Mr. Goschen, that "relief to able-bodied widows is liable to become an aid to wages, and that, as in the case of able-bodied men, the wages are commonly reduced in consideration of the allowance from the parish." The Guardians care for none of these things, so they seem to allow to every widow who applies a shilling and a loaf of bread for every child under the age of thirteen years. We really wish some ratepayer would bring an action against the Holborn Guardians to try the point whether they are to be allowed to go on systematically breaking the law in this way or no.

But it is not only with regard to widows that the Guardians find it impossible to avoid the practice of supplementing wages by relief, for it appears that more than 50 per cent. of the adult pauperism of London consists of persons more or less incapacitated from work by a acute or chronic diseases, or old age.

Of 3,411 adults relieved in one week, 1,812 were more or less permanently disabled. It was found that numbers of this class were receiving small wages, such as 2s. a week. But the Guardians are obliged to confess that this illegal conduct on their part, in relieving more or less disabled poor persons, increases the competition in the lower forms of labour to such an extent as to reduce the wages paid for it. Hence, the price of various forms of needlework could not be maintained at the present starvation standard, were it not that so much is done by persons seeking parochial relief.

Seriously, we reiterate our desire that some of the working class ratepayers would bring an action against these Guardians for illegally disbursing the parish funds, and destroying the independence of the poor London workpeople. "The industrious ratepayers are taxed to maintain thousands, who, for want of sobriety and thrift, have become claimants on their savings." The Guardians, also, are in the habit of paying rents in many cases out of the rates. Here the Poor-law Board seem to sanction what we consider to be a great abuse. They also seem to *lend money* to destitute persons in some cases. In short, it appears to us that the Guardians of the Holborn Union are doing all they can to lower the independent character of the London poor; and that, unless Mr. Goschen, or some other person in power, insist on the carrying out of the law, we shall go on from bad to worse, and London will become a pauper warren.

THE MUSCULAR LABOUR OF THE UTERUS IN PARTURITION.

THE Obstetrical Society of Dublin were the auditors, on Saturday evening last, of a most interesting and

Notes on Current Topics.

masterly communication on this subject from Professor Haughton, F.R.S., of which, not only were the details of the scientific investigation of the greatest interest, but the results obtained were of the highest practical value. The investigations were undertaken by Professor Haughton as part of the inquiry which he is about giving to the public in a work on Animal Mechanics. He applied himself to the testing of the relative mechanical power of the involuntary or uterine and voluntary or abdominal muscular system engaged in parturition; and by a variety of experiments and mathematical calculations, by ascertaining the weight of the muscles engaged, he has arrived at results which will, doubtless, astonish our readers.

He showed, with conclusiveness, that the expulsive force of the uterus, employed in dilating the os in the first stage of labour, amounted to 3·4 lbs. on the square inch; and he compared this result with the conclusion arrived at by Dr. Matthews Duncan, that the membranes required a force of 3·1 lbs. on the square inch for their rupture. Thus, he pointed out that the expulsive power of the uterus was just capable of rupturing the membranes and no more, and he illustrated by this comparison the beautiful and wonderful economy of labour evidenced in the human system. He found, however, that the expulsive force capable of being voluntarily exerted by the woman was enormously greater than that of the uterus, and was equivalent to 38·6 lbs. on the square inch, and he believed that it was by this force in the greatest measure that the expulsion of the fœtus was effected. He reduced his investigation to the following figures:—

Involuntary, or uterine force,	3·4 lbs. on square inch.
Voluntary, or abdominal force,	38·6 " "
Maximum expulsive power	42 " "

Which, calculating the fœtal head to have a diameter of $4\frac{1}{2}$ inches, would represent the enormous force of 593, or about a quarter of a ton, which *might* be engaged in parturition. He, of course, was aware that only a small proportion of this power was usually exerted.

The obvious practical bearing of this investigation on the use of chloroform in labour was pointed out by Professor Haughton; and he suggested that while it might be found useful in the very earliest part of each expulsive effort, from its temporary power of stimulating muscular action, its use afterwards was obviously injudicious, inasmuch as it paralysed the voluntary power, on which the process of parturition so much depended.

In the course of his observations, Professor Haughton alluded to an unexpected literary discovery into which this investigation had led him. His recollection had been struck by a passage from Tristram Shandy, in which the hero, in his conversation with Dr. Slop, states, on the authority of Lithiopædus Stenonensis, that "the force of a woman's efforts in strong labour pains were equal, on an average, to the weight of 470 pounds acting perpendicularly on the head of the child." Dr. Haughton, with great raciness, explained that he believed that this statement, which had been always regarded as a satirical allusion, was not really so at all, and that inasmuch as the coincidence in numbers was too remarkable and too improbable for mere guess work, he could not help thinking that Lithiopædus Stenonensis was a veritable authority on the subject, whose writings had been lost to posterity.

The communication is reserved for presentation to the Royal Society, and will, no doubt, be published in their Transactions; and it was on this special proviso that Professor Haughton tendered its principal facts to the Obstetrical Society.

We (*Nature*) understand that it is not the intention of the Government to fill up the vacancy in the curatorship of the Botanic Gardens at the Mauritius, caused by the death of Dr. Meller, but to promote the head gardener to the highest post of authority.

The Surgeon in Ordinary to the Queen in Ireland.

DISAPPROBATION has been unfortunately the vein in which journalists have usually been compelled to notice Governmental or Court medical appointments, and it has been but seldom that we have been allowed to vary our animadversions with a pen on the selection to offices of honour of a person universally accepted by the Profession as deserving. The distinctions accorded by Royalty to the Profession have been lately of such a character as to render it dubious whether Court honours, Regal or Viceregal, would be ever again objects of ambition to the Profession; and the latest appointments of Mr. Oscar Clayton and Dr. Nedley, against both of which we raised our voice at the time, were not without their effect in depreciating the public value of such honours.

The selection of Mr. Porter for the honour of Surgeon in Ordinary to Her Majesty in Ireland is a pleasurable and unexpected departure from the system which has prevailed in such matters, and we welcome the promise which it gives the Profession that professional merit may henceforth be an element in the calculation of chances for such offices.

There is no man in Ireland more deserving of such a distinction than Mr. Porter; nor could there be a selection which, apart from political considerations, will be more universally approved in Ireland. He is all that the Queen's Surgeon in Ordinary should be—the bearer of a name honoured in Irish Surgery; the Senior Surgeon to one of the first Hospitals in Dublin; the ex-President of the Royal College of Surgeons in Ireland; a Surgeon who has enjoyed the complete confidence of the public; and a man of well-recognized private worth and professional rank. To such men, rather than to political tricksters or the amusers of Viceroyalty, should such honours be given; and when such a desirable rule is adopted in their allocation, the Surgeoncies to Her Majesty will be worthy of the aspiration of such men as Mr. Porter.

The Theory of Poisoning by Phosphorus and Pyrogallic Acid.

DR. J. EMERSON REYNOLDS gave a short account of some new experiments on this subject at the last meeting of the Dublin Scientific Club. The following were the chief points referred to:—

M. Personne recently communicated to the French Academy of Sciences the results of some experiments which he regarded as singularly corroborative of his chemical theory of the poisonous action of phosphorus on the animal system. He believes that absorbed phosphorus poisons by abstracting the oxygen from arterial blood, and so neutralizing the aerating functions of the lungs. If this be the true *modus operandi* of the poison, any substance capable of preventing the oxidation of phosphorus ought to prove an antidote. It has been long known that the vapour of oil of turpentine greatly interferes with the action of oxygen on phosphorus. This circumstance led M. Personne to administer turpentine in several cases of acute poisoning by phosphorus, with the happy result of saving human life. Desiring to obtain further proof of the truth of his theory,

M. Personne sought for some chemical substance capable of absorbing oxygen with as great avidity as phosphorus does. He speedily fixed upon pyrogallic acid as being most suitable for use in further experiments. This substance, when present in a slightly alkaline fluid, such as blood, has the power of absorbing oxygen with great energy. Two healthy dogs were taken, and into the stomach of one a dose of two grains of pure pyrogallic acid dissolved in water was injected, while twice this amount was administered to the second dog. The animals died after fifty and sixty hours respectively, presenting most of the symptoms generally attributed to phosphorus poisoning; and on *post-mortem* examination the muscular tissue of the heart was found in each case to have suffered the fatty degeneration well known to follow the administration of poisonous doses of phosphorus. The antidote to pyrogallic acid would appear to be an acid solution of chlorate of potassium.

As pyrogallic acid is largely employed in photography, and has been hitherto considered a perfectly harmless substance, the fact of its possessing powerful toxic properties cannot be too widely known; but increased interest attaches to this circumstance, since it strongly supports the chemical theory of phosphorus poisoning proposed by M. Personne; for we have here two bodies whose *only* point of similarity consists in the energy with which each is capable of combining with oxygen, and both these substances are stated to act in almost precisely the same way on the animal economy.

I may add here that the chemical relation of pyrogallic to gallic acid is a very simple one, and the connection of both with common carbolic acid and benzole a matter to which singularly little attention has been hitherto given. This relationship may be shown in the following way:—

Taking benzole as the starting-point of the series, it is only necessary to replace one atom of hydrogen in it by the group OH, or hydroxyl, in order to produce carbolic acid. When this replacement of hydrogen is carried two steps further, we get pyrogallic acid; and when to this latter body CO_2 or carbonic anhydride is added, we have gallic acid.

Remarkable Injury of the Head,

PRODUCED BY THE DISCHARGE OF A PISTOL BALL WEIGHING ONLY FIFTY-FIVE GRAINS, AND PROPELLED BY SIX GRAINS OF POWDER FROM A SHARP'S PISTOL, THE SKULL BEING ONE-EIGHTH OF AN INCH THICK AT THE SEAT OF ENTRANCE.

A MAN, aged forty-six, in a fit of despondency, discharged the pistol close to his head. The ball entered the superior and anterior corner of the squamous portion of the right temporal bone, producing a stellated fracture, consisting of a superior fissure extending two inches, a posterior reaching quite to the occiput, and an inferior fissure running anteriorly across the greater wing of the sphenoid bone, to the orbital plate, producing a quadrangular-shaped fracture through the vault of the orbit, with sides from an inch to an inch and a fourth. From the greater wing, also, transversely across the body of the

sphenoid bone, separating the anterior clinoid processes near their base, breaking up the ethmoid bone and loosening the vomer, continuing over to the opposite side, making a triangular fracture of the left orbital plate, and ending with a fracture of the greater wing of the sphenoid bone of the left side, running down two inches in depth in the temporal fossæ. The ball was found in the medullary substance of the left anterior lobe, just in front of the fissure of Sylvius. It was flattened on one side, and rounded on the other, with a slight dent or concavity on the convex surface. The ball carried before it a circular piece of bone three-eighths of an inch—the size of the opening it cut in piercing the skull. The extravasation of blood was confined to the temporal muscle of the right side, although a fracture and ecchymosis was observed on the left side on separating the scalp, before raising the calvarium.

The fracture was not simply a seam, but a "simple fracture with displacements;" so that on raising the skull-cap, moderate force applied to the sections of the occipital and frontal bones readily separated the anterior and posterior portions of the skull through the course of the fracture, they being retained in position only by the attachment of the soft parts. This case is, in a measure, corroborative of the many facts accumulated by the earlier writers on surgery, to show that fractures on one side of the head occur from blows received on the other; for on exploring the skull, a fracture on the side opposite the wound was clearly observable. And also, creative of suspicion, that many recorded cases of this class of fracture were really continuous through the base of the skull.—*California Medical Gazette.*

The "Dry Earth" Method in Court.

AN American Jury have been called upon to decide the question as to whether the treatment of burns by "the dry earth system" amounts to malpraxis, or whether that line of practice is to be considered as a *bona fide* surgical proceeding, and defensible on scientific grounds. The *Philadelphia Reporter* furnishes us with the details:—

In June last a young woman, somewhat intoxicated, hurled a kerosene lamp at James Welsh, which struck the wall over his head, exploded, and covered him with burning oil. He was promptly removed to the Pennsylvania Hospital, where, by the direction of Dr. Hewson, the wound was dressed with dry earth daily. The patient complained of a great deal of pain and irritation in the wound, which led to an examination. The earth was found crusted and baked over the surface, and beneath this crust it was discovered that a large number of maggots had found a nidus, keeping up a distressing irritation. The man was walked down stairs, and necessarily exposed to some draught of outside air. The wound was washed by a continuous stream of water. Shortly afterwards tetanus supervened, and he expired.

The medical witnesses differed in their opinions of the severity of the wounds, some maintaining that they were slight, others that they were severe. Dr. Hewson testified that he considered them mortal. Certainly, however, the man did not die from the direct effect of the burn. The question was, was not the treatment the exciting cause of the tetanus?

There was a large cross-examination in regard to the effect of the "Earth treatment," the result being that the

witness—Dr. Hewson himself—deposed that the object in this case was to exclude the air, but other than this he was unable to tell the effect; that the pressure of this dressing did not affect the tissues beneath; and that the tendency of the earth dressing in a case of this kind is to assist nature.

Dr. Chapman, who was Dr. Hewson's assistant, testifies: "Dressed with dirt dressing right through, except glycerine and carbolic acid on one occasion; I think the dirt dressing increased the pain of the man; he complained to me about it, saying it pained him all the time except the first time I applied it, when he said it felt cool; he continued saying it pained him until the last time I spoke to him; I can't answer for what my chief did."

A number of other surgeons were called, but seemed to have no practical knowledge of the merits or demerits of the earth treatment. In opinion they seem to have disapproved of it.

Leaving aside all other questions in this case, Dr. Hewson appears to have granted on cross-examination that the only effect of the treatment at all sure is to exclude the air, and that it does so insufficiently both Dr. Chapman's testimony and the result prove. The charge of malpractice was virtually withdrawn by the defence.

It appears to have become a question of law how far a medical man may be justified in riding a hobby. There must be some limit where the vagaries of a surgeon must stop and where error of judgment verges on malpraxis, and in this particular direction the "dry earth system" seems to have reached the limit. We do not hesitate to say that it is almost criminal for a surgeon to adopt a line of treatment which he is himself unable to explain, and in favour of which no experience of success can be pleaded.

Immigrants into the States.

THE Statistical Bureau at Washington informs us that in the twelve months ending June 30, 1869, there were 389,651 immigrants into the United States, of whom 240,477 were men, and 149,174 women. Germany sent the most, 132,537; Great Britain, 60,286; Ireland, 64,938; Norway and Sweden, 40,292; France, 3,879; China, 12,874; Switzerland, 36,500. It will be seen by this table that Germany now sends out larger numbers of emigrants than Britain and Ireland combined, while France sends out scarcely any of her almost stationary population. Such facts may well make us reflect.

Verdicts of Coroners' Juries.

Two inquests were published in the columns of the *Downpatrick Recorder* last week. One held upon the remains of a woman who, the journalist informs us, died when she was preparing to take her tea, without medical evidence, as we gather from the report of the case—for the Coroner is a non-medical one—and upon whom the jury recorded a verdict of "Died by the visitation of God." The other inquest is a more remarkable one. A hawker of fish went with his horse to dispose of a load of fish; the horse came home, but the remains of the unfortunate fishmonger was subsequently discovered drowned, after being missed eighteen days, in a brick-hole of water, with his legs tied with the belly-band of his horse. In this case the verdict returned was "Found drowned." It would be interesting to know if a medical man examined the deceased, and

whether he died of drowning at all or not, and, if he were drowned, how to account for the "belly-band" being tied round the unfortunate deceased's legs, and whether the constabulary were directed to inquire still further into the case. Could it be possible for the man to tie together his own legs and then drown himself? The question has an important medical bearing, inasmuch as the ordinary run of coroners' inquests are little better than a farce, and the verdicts of the juries, returned at the dictation of the Coroner, incompatible with common sense; but this is to be accounted for by the fact that a non-medical Coroner is unable to see through the case in its several medico-legal bearings as a properly qualified and educated medical man is fitted by special training to do. We think in those cases of inquests presided over by non-medical coroners that medical evidence is an essential of great and indispensable moment; that justice be fairly and impartially administered. Our allusion to the two cases published in the journal alluded to is for the purpose of showing that the verdicts of the jury in either case were neither sufficient nor satisfactory. Suppose that the deceased was drunk, and had his legs tied together by some practical joker, who allowed him to wander home; or suppose that his legs were tied with wilful intent, and he was thrown into the hole wherein he was subsequently found. Surely such a verdict as that of simply "Found drowned" would be inadequate, and little better than a Coroner's inquest farce.

Causes of Mortality among the Children of the Poor.

In a recent inquest on the body of a child, aged nine years, Mr. Benjamin Lowne, jun., of Farringdon Dispensary, said, in evidence, "It was one of those cases in which the poor wished to get rid of their children. While they were living they wished them dead, and then they would get some one to bury them." A Juror.—"The poor are fond of their children." The Doctor.—"You do not see so much of them as I do. The poor have to support five children when they have not the means of supporting one. One half of the children of the poor die before they are three years old, while only 10 per cent. of the rich die before that age." It is clear that Mr. Lowne does not agree with the phrase, "Blessed are the poor;" and we daresay he would be found, on inquiry, to be an advocate for the small family system, so much recommended by some of our correspondents, as a cure for poverty.

Contagious Diseases Act of 1866.

WE hear that an Association of Ladies has been formed to oppose the extension of this Act to the civil population, and that Mrs. H. Martineau and Miss Nightingale are favourable to this protest against the Act.

The Southampton Infirmary.

THERE seems to be something very far wrong in the way in which appointments are made to this charity. Thus, Mr. R. M. Watson writes to a local paper that "such a combination as at present exists in the government of the South Hants Infirmary ought not to be permitted." This gentleman became Governor in 1868, and he complains that he never had a copy of the laws, and that the members of the committee are not fairly elected by the Governors at large. Mr. Hearne, of Southampton,

in a letter to the *Southampton Times*, seems much opposed to the Infirmary altogether, on account of the greater mortality which obtains in hospitals than in private houses. He complains that it was absurd to advertise, too, for candidates for the vacant offices, because the appointments had already been made virtually long before the advertisements appeared, by some body of persons in power. This is not as it should be. It is a disgrace that our public charities should be so mismanaged as they too often are; and we can see no way out of the difficulty save by employing the only fair test in such appointments, viz, that of competitive examinations.

Another Piece of "Medical Charity."

It appears that at Ruabon, in Wales, there is to be an accident ward kept up by a local magnate and his friends. Very good. But what follows? The "medical men shall not receive remuneration under any circumstances out of the funds of the hospital;" and, after this, we hear that these gentlemen have "agreed to provide gratuitously medical and surgical appliances, which will be a great saving to the institution." We are at a loss to say whether the conduct of the Governors or the medical men is the more astonishing. Are medical men slaves to do all the work of the country for nothing?

Gratuitous Services in Hospitals.

THE inquiry recently instituted into the condition of St. Bartholomew's Hospital, and the results arrived at, suggest to many of us the idea that both the committee and the medical staff should consist of paid officials. In Paris there are now no unpaid persons connected with hospitals, and the same thing should, ere long, be brought about in London. Persons who are paid are, of course, liable to be removed if they do not fulfil their contract, whilst gratuitous services enable members of committees and medical men to neglect the interests of the hospital whenever they please.

Royal Institution.

THE lecture arrangements of the above Institution have been announced, and the following addresses are promised:

CHRISTMAS LECTURES (ADAPTED TO A JUVENILE AUDITORY).

Prof. Tyndall.—Six lectures on "Light."
BEFORE EASTER.

Prof. Humphry.—Six lectures on "The Architecture of the Human Body."

Prof. Odling.—Twelve lectures on "The Chemistry of Vegetable Products."

Robert Scott, Esq., M.A., Director of the Meteorological Office.—Four lectures on "Meteorology."

Dr. Masters.—Two lectures on "Plant Life as contrasted with that of Animals."

Prof. Rolleston.—Four lectures, "Deductions from the Comparative Anatomy of the Nervous System."

Prof. Max Müller.—Four lectures, "An Introduction to the Science of Religion."

Joseph Norman Lockyer, Esq.—Four lectures on "The Sun."

AFTER EASTER.

Prof. Blackie.—Four lectures on "The Principles of Moral and Political Philosophy."

Prof. Tyndall.—Seven lectures on "Physics." On Thursdays.

Prof. Robert Grant.—Seven lectures on "Astronomy."

Prof. Seeley.—Three lectures on "History."

The Friday Evening Discourses will probably be given by Dr. Tyndall, Dr. Odling, Professor Ruskin, Dr. Carpenter, Mr. Clifford, Sir Henry James, Professor Sylvester, Mr. Peter W. Barlow, Dr. Rolleston, Professor Roscoe, and Professor Huxley.

The Visiting List.

OF all pocket-books for medical men, "The Visiting List," published by Messrs. Smith, Long Acre, is most popular. We have looked over our copy of V. L., 1870, as it is concisely lettered at back, and find it equal to its many predecessors. We think the publishers are entitled to ask why every practitioner in the three Kingdoms should not use their excellent diary. We have used it for some years—like it very much—and mean to go on using it.

The Doctor's Little Bill.

AS Christmas draws near, the general practitioner is preparing to send in his account. Many a one is not a little annoyed by the process of making out his bill, and scarcely knows what form to adopt. Messrs. Merritt and Hatcher, of the Poultry, have sent us specimens of various lithographic accounts, some being facsimiles, of several sizes. From them anyone would be able to select the style that was most in accordance with his taste. The use of such a form would save both trouble and expense.

The Metropolitan Free Hospital.

THE movement for the remuneration of the medical officers to our various hospitals and dispensaries is gaining ground. The committees of the hospitals should be paid also, and then we should have no more trashy sentimental expressions of gratitude to the medical men, in lieu of real substantial thanks. The Committee of the Metropolitan Free Hospital, though themselves unwilling to do anything towards helping on the cause of their medical staff, have promised to call a meeting of the Governors to consider the remuneration of the medical officers. We hope that the movement will be a general one.

A "Large Family."

A WOMAN, says the *Wrexham Guardian*, in this neighbourhood has been delivered of four children at a birth. The Queen has sent her £7. She has had on two previous occasions three at a birth, all of which have lived. What would Malthus, Mill, and their school say to this? If all women were like this, we might double in ten years or less.

Relapsing Fever and the Jews.

MR. D. H. DRYE, the able medical officer to the Jewish Board of Guardians, Devonshire-square, Bishopsgate, has arranged that a sanitary inspector should visit frequently the dwellings of the Jewish poor, to see that their dustbins are emptied, the closets clean, and that there is a sufficient supply of water. The amount of relief weekly is to be increased, as it was in the cholera epidemic of 1866.

Numbers of very poor German and other foreign Jews swarm over to this part of the metropolis, and make a great inroad into the funds provided by the charity of their richer co-religionists.

Imperforate Hymen.

A CASE of this uncommon malformation occurred recently in the practice of Dr. Charles Drysdale, at the Metropolitan Free Hospital, in a girl aged fifteen, whose abdomen was much enlarged from the retained menses. A very small puncture with the end of a fine bistoury was made, the fluid escaped, and the young woman is now well.

Relapsing Fever.

DR. BROADBENT, speaking of the recent epidemic of this complaint, mentions that the relapse takes place with the greatest regularity on the 14th day after the first rigor, and that the temperature rises frequently to 104° Fahr. The diagnosis between relapsing fever and the severer forms of typhus and typhoid is evident enough. Typhus comes on abruptly and causes severe suffering, and typhoid fever is characterised by a peculiar appearance of the countenance and by the rash.

Law Court Ventilation.

WE are glad to see that attention is being called to the bad ventilation of some of our law courts. They are often almost as pestiferous as some of the theatres of our large cities, and require great alteration.

The Sharpey Memorial.

Up to July last, nearly £1,400 had been subscribed to this admirable fund, which is to be used, we believe, for the foundation of a Sharpey Physiological Scholarship at University College. Sir W. Jenner is the treasurer.

Hospital Nurses.

ST. GEORGE'S HOSPITAL advertises for nurses. Head nurses to receive £30 a year, with board and lodging, &c.; night and assistant nurses £18, with board, lodging, and "no scrubbing." St. George's has 300 beds and 55 nurses, in addition to the head nurses. We are much opposed to the religious nurses of some of our hospitals. As Miss Nightingale says, the religious orders are all too solicitous about preparing patients for death to be good nurses.

Dr. Barnes on Uterine Hæmorrhage.

WHEN compression, cold, and ergot of rye fail to produce stoppage of post-partum uterine hæmorrhage, owing to loss of nerve power, Dr. Barnes recommends the injection of the perchloride of iron before collapse sets in. Dr. Tyler Smith recommends a full dose of ergot of rye immediately after the birth of the child to prevent hæmorrhage.

It appears that a person called Henry Jacob Jordan opened an Anthropological Museum at Melbourne, Australia. This museum was similar, we suppose, to those seen in London. The Melbourne papers attacked the proprietor, and it seems he brought an action against them for it, which was given in favour of the defendants.

Repression of Contagious Disease.

IN our impression of December 1st reference was made to the working of the Contagious Diseases Act in some garrison towns to which it has been extended. The question is, no doubt, of much importance to the community at large, and deserves careful consideration, more particularly as, in order to carry out the provisions of the Act, the liberty of the subject is liable to be interfered with, and the patient to be submitted to compulsory treatment. Whether we can limit or restrain the extension of disease, provided sufficient power was given to segregate the diseased and submit them to proper treatment till cured, is the great question of medical interest; and as we have been supplied by Dr. Burnside with some valuable practical information on the subject, the following account of a vigorously conducted limitation, under favourable circumstances, proves that not only can the disease be limited, but actually "stamped out" in a district:—

"When H.M.'s 51st Regiment was stationed at Moorshera, in the Punjab, there being no other troops in garrison, the surgeon was happily enabled to eradicate venereal disease from amongst the men by having the following measures strictly carried into force:—

"1. The women in the Regimental Bazaar were registered. These varied in number, but the average was about twenty. A chief (Mildaree) was appointed, whose duty was to see that the orders were carried out as to extreme personal cleanliness of their persons and dwellings, &c.; each of them, except the Mildaree, paid a rupee a month. The fund thus formed was expended in renting a house for a Lock Hospital, and also went towards their sustenance when under treatment.

"2. Frequent and careful examinations of the women. On the least trace of disease being found, even abrasion of the mucous lining of the vagina, the patient was at once placed in hospital, and the Mildaree made arrangements for having her food purchased and cooked, so that she might have no communication with anyone else outside.

"3. The men were given distinctly to understand, by a regimental order, that if any one infected with venereal reported it at once he would be treated as an ordinary patient; but that if the disease was concealed for any time, or only discovered on the weekly 'health inspection' being made, he would be admitted as a prisoner, and have to make good the number of days he was under treatment on his discharge from hospital, by doing double duty, or punished in any other way the Colonel might see fit.

"4. The inspection was very carefully made in the following manner:—The men were marched up by companies, and passed singly through an upper door in one of the verandahs, the Assistant-Surgeon on duty being seated inside. After the examination they went out through a lower door; thus all exposure was avoided, the Sergeant-Major remaining within call during the inspection to take down any names."

Dr. Burnside assures us that at the expiration of four months from the date of the first application of these stringent regulations the disease had much abated, and at the end of six months had completely disappeared in the district under control. This fact is encouraging with regard to the conferring of greater powers as to compulsory treatment.

MR. ACTON will read a paper on the Contagious Diseases Act of 1866, on Saturday evening next, Dec. 18th, at 7:30, at Crane-court, Fleet-street, in the rooms of the Association of Officers of Health.

At the Clinical Society Dr. Oppert relates cases of syphilis treated by subcutaneous injection of mercury. This plan is not devoid of danger, is painful, and we question whether it is of any use.

DR. BLACK has been appointed Physician Accoucheur to Charing-cross Hospital.

FEVER is progressing at Holbeach Common. Six cases have been reported by the medical officer, Dr. Harper.

WE hear that a resident surgeon has been temporarily appointed for the Highgate Infirmary.

WE regret to hear that Miss Nightingale has been for years a prisoner in her room from ill-health.

SCARLET fever occasioned 245 deaths in London last week. Sheffield, Liverpool, and Hull are also suffering greatly from this fatal disease.

DR. PLAYFAIR recommends nearly concentrated carbolic acid as an application to the interior of the inflamed cervix uteri in uterine catarrh.

MR. HOLMES COOTE is opposed, in cases of amputation, unless where there is sloughing, to the carbolic acid treatment in any shape.

THE Chatham Hospital for Women under the Contagious Diseases Act is soon to be opened. Surgeon-major Barden is the surgeon to it.

THE symptoms characterising syphilitic brain disease are unilateral convulsions, double amaurosis from optic neuritis, palsies of several cranial nerves, and hemiplegia. Dr. Hughlings Jackson has several like cases under his care at present.

DR. CHARLES THOMPSON says that he has found that warm baths at the outset of scarlet fever is the most curative of all therapeutic remedies. He has, he says, used them for fifteen years, and never has lost a patient when seen in time.

DR. J. SENIOR TURNER has been re-appointed medical officer to No. 5 District of the Mansfield Union, on the motion of Mr. Oscrift, seconded by Mr. Oates, and carried unanimously.

WE are much pleased to hear that the teaching of natural science is now universal in Cambridge. At St. John's College, it appears, natural science is on the same footing with classics and mathematics. In our day it was nowhere.

It appears that at Southampton, a homœopathic medical man has applied as candidate for the appointment left vacant by the retirement of Drs. Palk and Griffin from the Southampton Dispensary. He did not, however, we believe, go to the poll with the other candidates.

A LODGING-HOUSE keeper has been convicted and fined eight shillings for having failed to give notice that a little girl was lying ill of typhoid fever under his roof. Is typhoid fever contagious? We believe it is; but it is not *very* contagious.

DR. BURZONJEE, a Parsee gentleman, has resided in England for ten years past, and is now about to return to Bombay in order to superintend, with his wife and family, a school for the instruction of native girls in the higher elements of female education.

ACCORDING to the Sanitary Commissioner of India, D. Cunningham, the mean mortality per thousand troops in the 10 years ending 1869, has been in Northern and Central India, 30. There are now only 31,560 British troops in Bengal. Of every 100 deaths 17 were due to liver disease, 14 to fever, 13 to heat apoplexy, 9 to cholera, 8 to consumption, &c. More than 365 English soldiers were daily sick from "contagious diseases," only 8 per cent. of the soldiers being married. The death-rate of 3,196 women was high—31.60 per 1,000—and of children excessive, 87 per thousand per annum. The sepoy's live much more easily in their own climate, having a mortality of only 16.19 per thousand.

THE papers just received from India contain several items of what may be called professional intelligence. The Sanitary Commissioner for Bengal having published his Statistical Report for 1868, the death-rate for that year among British troops throughout that Presidency appears to have been 20.11 per 1,000, the rate of invaliding 45.49, being about the smallest ratio of mortality yet recorded. This happy circumstance is attributable to the absence of cholera during that year. No "service" appears to have taxed the powers of the troops, and the hot season was unusually temperate; but, inasmuch as the figures only represent those struck down actually in India, they fail to indicate the real extent to which our troops did suffer during the period in question, as no account could be taken of those who have, since their arrival in Europe as "invalids," succumbed to diseases contracted in India. It is only by returns in which both these particulars are given that we learn the true rate of non-efficiency due to service in India. Any others are calculated to mislead, and hence the value of statistics prepared in India must necessarily be seriously impaired. Fortunately, however, the Report of the Medical Department of the Army for 1868 will soon appear, and in it we shall doubtless find that information which we cannot expect to obtain from India.

WE learn that the Director of Military Gymnastics has reported to the Sanitary Commissioner for Bengal that the running drill lately introduced into our Army there is "a valuable agent of sanitation"—a fact very satisfactory in its way, only we fail to see how the first of these functionaries has obtained the professional knowledge necessary to enable him to judge regarding the effects of that exercise upon the great organs connected with circulation and respiration, while such things are known to have happened as men falling down during such drill from the sudden rupture of aortic aneurisms. Neither can we see what the Sanitary Commissioner has got to do with the matter, so long as we maintain a large staff of Army Surgeons in India to look after and attend upon our soldiers in health and in disease. There has been a great deal too much of so-called "sanitation," not only in India, but in our own country. The prevention of disease is as much a part of medical science as is its cure, and the absurdity of the late attempts to separate them is at last becoming so apparent that probably before long the Indian Government will see

the practicability of looking to the officers of the Army, and to them alone, for information and suggestions regarding all departmental matters.

Unfortunately, we have reason to fear that the statistics of 1869 will show very much more unfavourable results than those for 1868. What with the extent to which the 58th Regiment suffered from cholera at Allahabad, and the 36th at Peshawur, the general rate of mortality will, no doubt, approximate more to its ordinary standard than it has done in the past year. Then we learn that the 85th have suffered severely from fever at Meeanchur, the 41st at Sobathoo, the 92nd at Jullundhur, and that sickness to a considerable extent prevailed at several other stations in the north-western provinces.

SPECIAL CORRESPONDENCE.

PARIS, Dec. 10, 1869.

WINTER has come in earnest. The month of December had scarcely begun when old-fashioned Christmas weather set in. In the first few days we had a heavy snow and hard biting frost, and began to think we had mistaken our latitude and put up at some more northern city. In Italy I hear it has been just the same. Premature severity everywhere. Even favoured localities in the sunny South have already felt an unusual degree of cold, and it seems probable that many a bishop at Rome will remain in the eternal city a long time to recover from the effects of a sudden cooling of the air. As far South in France as Bayonne, the border town, which seems in appearance and language half Spanish, there is more snow than has been known for a number of years, and the inhabitants are accordingly suffering a good deal.

Piedmont is always cold, and, therefore, the accounts from Turin need disturb no one.

The great question of the day here is animal vaccination, on which the Academy has at last pronounced an opinion. The meeting was, however, a stormy one, the differences of opinion being very great. M. Depaul is the great champion of vaccination from the heifer, declaring the animal cannot have syphilis.

Others, however, were of a contrary opinion, and MM. Guérin and Ricard seemed to say, if they were bound to admit that the heifer was proof against syphilis, there were diseases of animals that had not been proved incapable of being transmitted to man. At last the Academy sanctions animal vaccination, but not its exclusive employment. Vaccination from child to child is still to be the recognised plan; that from the heifer being permitted also.

Last year I complained much of the post-office. It is stated that we are to have a reduction in the price to London. I hope other reforms will be included in the new agreement with St. Martin's le-Grand.

BELFAST, December 7.

DURING the last four months a severe epidemic of scarlet fever has prevailed in Belfast and neighbourhood, principally confined, however, to the lower orders. This disease has been accompanied by a good deal of infiltration and swelling of the neck, in many cases ending in abscesses which have quickly suppurated. Two deaths of members of the Profession have occurred—viz., Dr. David Moore, one of the dispensary medical attendants, who died in June last from typhus contracted in the discharge of his duties, and more recently Dr. Stephenson, the senior member of the Profession in Belfast, and a consulting physician of this town. The latter gentleman died suddenly from apoplexy. As a mark of respect the Profession attended both funerals.

The Town Council last week elected one of their body, Dr. S. Browne, surgeon to the General and Ophthalmic

Hospitals, to be mayor for the ensuing year. Dr. Browne has been for several years a member of the Council, and conferred great benefit on Belfast in connection with sanitary matters.

There is a large number of students attending the medical classes at the Queen's College, I believe over one hundred. Several interesting operations have been performed at the General Hospital, which contains 150 beds, and is the only recognised medical and surgical hospital in Belfast. This institution presents peculiar advantages for the study of operative surgery in all its branches, accidents being constantly admitted from the various factories, ship-building yards, &c. Also two exhibitions of considerable pecuniary value are connected with it—viz., the Malcolm and Charter's exhibitions. I have been informed that special classes are also in operation at the Ophthalmic Hospital and the Skin Hospital; indeed, to make Belfast complete in offering every attraction and more than ordinary advantages to gentlemen pursuing their medical studies, it only requires that the consent of the Governors of the County Antrim Lunatic Asylum be obtained to allow a limited number of students to attend the practice of that institution, mental diseases being a subject totally neglected at present, and it appears that at the last meeting of the Medical Teachers' Association a resolution making this study a compulsory subject was submitted. In addition to the above classes, a short course on the diseases of women and children, at the Lying-in Hospital, and also on the theory and practice of vaccination might be established with advantage.

The annual dinner of the Ulster Medical Society takes place to-day. The President for this year is Dr. J. Smith. Although the session has just commenced several important papers have been read. In conclusion I can only refer to the recent Poor-law investigation at the work-house here, by Dr. Kuox, into a charge brought by some of the Guardians about allowing medical students to attend dispensary midwifery cases, and which was only proved in one instance. The investigation is fully reported in the two last numbers of the Journal of the Irish Medical Association (*the Weekly Supplement to this Journal*).

Correspondence.

"DR. BIRCH AND THE REVIEW OF HIS WORK ON OXYGEN."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—After perusing the admirable effusion (Review! of the 2nd edition of my work "On the Action Use and Value of Oxygen" as a Therapeutic Agent), which you did me the favour to insert in your last week's issue—the question arose, whether to treat it with silent contempt as carrying its own condemnation to the mind of every gentleman among your readers, or whether to treat it as *libellous*, as well as low and unprofessional in its tone. I am duly advised on no account to permit it to pass with impunity. It may have escaped your editorial eye, I cannot but think. As a preliminary, then, I claim (even as a matter of courtesy) the *prompt* insertion of these few lines in your next week's number, with a suitable apology *satisfactory to myself and friends*.

The *ipse dixit* of a reviewer may be estimated at its exact value—the expression of an *individual* opinion, good or bad; and, in this instance, the very excess of personality and discourtesy of tone and style may defeat its own object by exciting the interest of many of my professional brethren in general practice, thus unintentionally promoting the object (which, as a London consulting physician, I must have at heart)—a more careful and extensive perusal, of which, experience has proved to me, I need not be afraid.

Your reviewer is compelled to admit the notoriously unsatisfactory state of therapeutics, and the difficulties which he himself feels; yet he makes no allowance for me, in his evident determination to "put him down." (Perhaps he may find in me a "Macduff" in more ways than one, though I am naturally a man of peace.) Evading the risks of an

open and detailed attack upon my scientific *ποι στῶ* and its imperfections, he confines himself (with no lack of words) to the logically easy task of vague insinuations about physiology and pathology, coupled with cunningly-devised misrepresentation—selecting a few words of mine, separating them from the context, and fitting them into his own sentences as convenient for his purpose—while letting out his prejudice against, if not his ignorance of, that great fact of natural science, that the laws of “imponderable force” regulate, give life to, and render available all things in the material universe, and hence (as a logical sequence) that physiology, pathology, and therapeutics are subservient to those laws, and must ever remain imperfect and obscure without an improved knowledge of their application in medical study.

And now to the special point of unprofessional and *libellous* remarks, ignoring common courtesy—only equalled by the want of logical acumen—on the part of your reviewer. *Furor iraque mentem precipitant.* First, he satirically calls my clinical selections “wonders,” “miracles,” and worthy of (if true) “from a grateful people some national recognition”—too good, in fact, for his limited apprehension and ignorance of oxygen in its therapeutic relations. Next, mark this! those very striking cases “are worthless as evidence,” &c. Did any of our judges ever enunciate the law of libel? Where, again, are Medical Ethics? I am but too well aware, having suffered therefrom, that I have made some spiteful private enemies among the children of self-conceit (I regret, but cannot help it); in consequence of effecting cures with oxygen, where others have failed in difficult cases. Hence *malus animus* here and there; although I defy anyone to name a single instance during twenty years’ practice, in which I have taken the slightest unfair advantage of a professional brother, notwithstanding that I have had plenty of provocation.

Obviously (were it not for some feeling in my own mind against a professional scandal, which the public in general so much enjoy) my own protection and *personal interests* would infinitely be best secured by a resort at once to a court of law, with the view to *prove legally*, through grateful witnesses and the inexorable logic of facts, many of my best “clinical selections;” while your reviewer’s discomfiture (if compelled to emerge from his inglorious position as *anguis in herba*) would be complete, by means of a little (pleasant) cross-examination regarding his knowledge and writings about oxygen as a therapeutic, as well as touching *his age*, whether (a) he was at school when I first took up the subject, and then read my paper before the British Medical Association; or (b) whether, being as old as, or an older man than, myself, he winces under and attempts to ignore the facts contained in the Preface and other parts of my second edition, although (*now*, so late in the day) he has the cool assurance to add, “our own experience leads us to believe that oxygen may in some cases be used with much advantage.” In the latter case (assuming mature years) “we” must have wonderfully changed “our” opinion.

In conclusion, I am prepared to vindicate my own views (as well as any apparent neglect in satisfying routine, wherever clinical minutiae, as I explained by anticipation, would be tedious and useless) against all courteous critics and opponents who may afford tangible ground for reply.

I remain, Sir, your obedient servant,

S. B. BIRCH, M.D.

61 Harley street, December 3, 1869.

N.B.—I have retained a *duly certified* copy of the above, in case of emergency.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I feel that it is due to the readers of the MEDICAL PRESS AND CIRCULAR, to state, in reply to Dr. Birch’s letter, that the review of which he complains was written by one who is a perfect stranger to that gentleman.

The opinions expressed in the review were formed after a careful perusal of every page of the work in question.

I fail to find in Dr. Birch’s letter any reason for altering these opinions.

I am, Sir, your obedient servant,

THE REVIEWER.

* Several letters, from want of space, are unavoidably postponed.

NOTICES TO CORRESPONDENTS.

J. D.—Any one may proceed before a magistrate against an unregistered person if he can prove the fact of his practising. Many cases have quite broken down owing to the clause in the Act not being sufficiently strict.

P. C. J.—A person who signs M.D. without possessing the degree, commits an impudent fraud on the public, though if registered as a medical practitioner, it would not be easy to take any step toward preventing him from so acting. Exposure would be the only course, but it is necessary to be quite sure the degree may not have been obtained since the registration.

HARVEIAN.—The paper for to-morrow evening will be by Mr. Curgenven, on Quinsey.

ADMISSION OF PAUPER-PATIENTS INTO HOSPITALS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—My attention has been drawn to a paragraph in your issue of the 6th inst., stating, “that the authorities of King’s College Hospital cannot entertain the proposition made by the Poor Law Board to take in pauper patients. They believe that they have no more room than is required to accommodate patients sent by subscribers.”

I beg to inform you that such is not the case, and that the committee of management have already made arrangements to receive as many pauper patients as their wards can accommodate.

I may also add that no sick person is refused admission into the Hospital for want of a subscriber’s letter, and the vast majority of cases are admitted without such letters.

I am, Sir, your obedient servant,
King’s College Hospital. J. W. WALDRON, Secretary.

ERGOT OF RYE AS A THERAPEUTIC AGENT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The members of the Medical Profession who have occasion to use ergot, and I cannot rely on the preparations of the Pharmacopœia, will doubtless have recourse to some preparation, such as Dr. J. W. Curran has recommended in his able paper on “Ergot of Rye,” which recently appeared in your columns. It would be interesting to know more about the way in which the new preparation is obtained, its dose, and its peculiarities. Will it be more effective than the simple infusion with borax, obtained from the same weight of the drug?

St. Thomas’s Hospital. N. T. T.
London, Dec. 9, 1869.

VACANCIES.

- Royal Albert Hospital, Devonport.—Junior Surgeon.
Raddiffe Infirmary, Oxford.—House-Surgeon. Salary progressive from £105. See advertisement.
Westminster Hospital.—Resident House Physician. No Salary, board and residence free. See advertisement.
German Hospital, Dalston.—Physician, and Assistant-Surgeon. Honorary appointments. See advertisement in last week’s Journal.
Downpatrick Lunatic Asylum.—Resident Medical Assistant. Salary £90, with board and residence. See advertisement.

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS, &c., RECEIVED.

- The Pathology and Therapeutics of Mental Diseases. By J. C. S. Van Der Kolk. Translated by J. T. Rudall. F.R.C.S. London: John Churchill and Sons.
Lectures on Surgery. By James Spence, F.R.S.E. Part II. Edinburgh: Adam and Charles Black.
A Treatise on Asiatic Cholera. By C. Macnamara, Surgeon to the Calcutta Ophthalmic Hospital. London: John Churchill and Sons.
The Cure of the Social Evil. By F. W. Newman.
Observations on the Contagious Diseases Act. By C. Bell Taylor, M.D., F.R.C.S.
An Historical View of Vaccination. By Vigorniensis. Cheltenham: J. S. Hadley.
A Manual of Tooth Extraction. By J. Gorham, M.R.C.S. London: Robert Hardwicke.
The Pathology of Bright’s Disease. By W. B. Lewis, M.D., New York.
On the Temperature of Children in Phthisis. By James Finlayson, M.D. Glasgow: Dunn and Wright.
The Physician’s and Surgeon’s Visiting List for 1870. London: Smith and Co., Long Acre.
Professional Diaries. London: Letts, Son and Co.
Philadelphia Journal of Medicine; Boston Medical Journal; Hardwicke’s Science Gossip; Nature; the American Journal of the Medical Sciences; the Monthly Microscopical Journal; the Practitioner; Australian Medical Gazette; Journal de Médecine de Bordeaux.

Births.

- GELSTON.—On the 6th inst., at 62 George street, Limerick, the wife of Dr. Thomas Gelston, of a son.
MOFFAT.—On the 10th inst., at 6 D’Olier street, Dublin, the wife of Robert Y. Moffat, of a son stillborn.

Deaths.

- ADAM.—On the 3rd inst., at Boulogne-sur-Mer, J. Adam, Surgeon, Madras Service, retired, aged 71.
BOWRA.—On the 26th ult., at Jersey, Henry G. Bowra, M.R.C.S.E., late of Charterhouse square, and De Beauvoir road, Kingsland, aged 65.
COLLIER.—On the 4th inst., at Ripon, the infant daughter of T. Collier, M.R.C.S., aged 8 days.
EVANS.—At Herne Bay, Geo. Wm. Evans, M.R.C.S.E., aged 66.
FOLLIOTT.—On the 25th ult., at Stapely Cottage, near Nantwich, of paralysis, James Folliot, M.R.C.S., the beloved and only son of the Rev. James Folliot, aged 34. Friends will please accept this intimation.

Introductory Lecture

DELIVERED AT THE

UNIVERSITY OF GLASGOW,

NOVEMBER 2ND, 1869,

By GEORGE H. B. MACLEOD, M.D., F.R.C.S.E.,

Surgeon to the Royal Infirmary and Lock Hospital; Regius Professor of Surgery.

(Continued from page 475.)

It is true that a certain amount of systematic instruction can be acquired from Books, but I utterly deny that such information can equal that to be procured from well arranged and properly illustrated Lectures. The lecturer has the best opportunity of explaining and anatomising (as it were) his subject,—of repeating and elucidating any obscure topic when he sees, as he comes to do as by an electric flash over the faces of his audience, that the subject is not sufficiently understood. By reference to the candid countenance of that useful member to be found in every class to whom Sydney Smith would irreverently apply the term "Foolometer,"—in whose perturbed expression the faintest obscurity reveals itself, the lecturer can always know if he has made himself comprehended. It were indeed strange if by the use of diagrams, casts, and dry and recent preparations, and by the accumulated research of the whole literature of the subject, a lecturer cannot inculcate his subject infinitely better than any book however carefully constructed and read. And yet, mark! lectures do not preclude reading, but, on the contrary, if the utmost good is to be got from attendance on such prelections, careful and systematic reading must accompany them.

Before leaving this point I would make one further remark, that while all cannot obtain the opportunity of manipulating in the hospital they can in the class-room follow a complete course of surgical operations,—a course in which each member may himself repeat (after preliminary instruction) each operation, and apply all the usual bandages and apparatus. This I look upon as

a most important part of my functions here, and I intend fully to develop it. I believe I was the first in the Glasgow School to give a complete course of instruction in Operative Surgery, and that I began when last I had the honour of teaching here. It is, to my humble mind, incomprehensible how Operative Surgery is not accounted a necessary part of the medical curriculum. How much anxiety would the practitioner avoid, and how many valuable lives would be saved, if a competent knowledge of Operative Surgery were possessed by all! No book can teach it, nor can it be learned in the hospital theatre. Many of the more usual operations are rarely seen at all in a hospital. Then how seldom are the details of such every day procedures as putting up a fracture, making a "scultitus," passing a catheter, or even adjusting a roller, explained during the stated visits in the hospital! Now I hope to teach you these essential things here.

I have a word or two to say regarding hospital attendance, which I beg of you to allow me to express. I hardly think a student can begin too soon to frequent the out-door department and even the wards of an hospital. It is true that for a time much that he sees and hears will be unintelligible to him, yet by degrees and insensibly he comes to recognize the features of disease, to employ his senses and get moulded to his work. I will not occupy your time by descanting on the well-worn theme of cultivating a habit of careful observation and recording of cases, though all must admit its extreme importance; but I feel convinced that nothing is of more consequence than concentrating your attention for a time on a few cases only, and not trying to grasp too many. A few cases, or even one general principle thoroughly mastered, would prove of much more value to you in every way than a multitude superficially observed and imperfectly comprehended. It is not, believe me, the rare or remarkable cases in a hospital which would be of real use to you to watch,—these, though curious, may never be encountered again,—but it is the apparently common and ever recurring ones just because they constitute those which you will have most to do with in practice.

It is by the educated and intelligent observation of facts, and the acute perception of their import and teaching,

that progress in medical, as in other sciences, is chiefly to be made. Scientific observation, however, implies more than the mere objective perception of facts. It also includes the classification of them and the deducing of logical inferences therefrom. A man may see and yet not observe, and it demands a well-trained and orderly mind to reason clearly and logically from such observations. It is in giving one this power of inference that an acquaintance with Mathematics and Mental Philosophy is so essential.

It is a well known saying of Cullen that "there are more false facts than false theories in medicine," and if the power of estimating the value of evidence were more common in the profession those terrible scandals in courts of law regarding the discrepancy of medical opinion would more rarely occur. When fully prepared to observe one student may at a glance gain more information than another, not so well educated, can ever obtain. It is not too much to say that in many instances an educated observer can read the whole history of his patient and his complaint before the patient utters a word. From the face (which Coleridge used to say was always either a history or a prophecy) and the expression,—from the gait and manner,—from the attitude and mode of address,—from the tone of voice and respiration;—from the colour of the lips and face and from the hand and its grasp,—in short, from many seeming trifles which would pass unnoticed by the uneducated—a whole volume of knowledge is obtained, and the line for future investigation at once mapped out. But you are not to infer from this that in the investigation of disease so rapid a progress is usually made. To discover new facts long years of patient research are often required. Harvey worked for eight years at the proofs of the circulation before he made his views public, and it took twenty-five years more before his opinions were accepted. Jenner was twenty-three years maturing his views by patient and anxious "trying." It took even longer for Sir Charles Bell to complete his investigations on the nervous system. All of them met with bitter opposition and ridicule, but they did not falter.

In all education, medical or other, there is probably no principle so important as the encouragement of self-culture and self-reliance. The lives and opinions of our greatest men amply justify this assertion. "Self-activity," said Sir William Hamilton, "is the indispensable condition of improvement, and education is only education, *i.e.*, accomplishes its purpose only by affording objects and supplying incitements to this spontaneous exertion. Strictly speaking, he adds, "everyone must educate himself." Here is a truth of vast importance. A teacher best fulfils his duty when he guides, directs, suggests, aids and incites, and the student when he studies, reflects, engages in independent research, and recognises his individuality and self-responsibility. Think and judge for yourselves. "Think wrongly, if you please," said Lessing, "but think for yourselves."

It is in truth the knowledge that a man wins by his own labour that he values most. It does not stand outside of him, as it were, but becomes a part of his being and is ever ready at his hand. It continues, when much that he heard from others vanishes. Food taken into the body is only of benefit if it be assimilated, and the self-exertion by which the knowledge is acquired begets new power and energy. Alas! it is one of the great barriers to human progress that every man carries much of this information and incommunicable experience with him to his grave.

In reading connected with lectures it is of great consequence to confine your attention for the most part to the subject discussed, and to try thus and master it thoroughly. Read carefully and attentively everything you can lay your hands on regarding what you have heard described in the class-room or seen in the hospital and get *that* well fixed in your minds. It would save you much repetition and trouble afterwards. I would also

encourage you greatly to cultivate, if possible, the older authors,—the Fathers and Classics of our Profession. Go thus as much as possible to the fountain-head, and you will be refreshed by the clear unadulterated stream,—the wisdom and thought of the past. With much possibly that is discarded and useless you will find many golden hints, unbiassed observations which are often mines of suggestive thought. The germs and more of recent "discoveries" will be there found by you, and thus you will be better able to appreciate the real advances of our science, and possibly to aid her in her march. We must surely know what has been already done before we can comprehend what remains to be accomplished. Much that is now laboriously pursued would be thus abandoned as having been already weighed and found wanting, and we would be spared the periodical resuscitation of not a few of those endless theories and methods of practice which distract men's minds, if a more thorough acquaintance with the past history of our art were possessed by its cultivators. Man, it is said, is the heir of all the ages, but he can only acquire his inheritance by assuming its possession. "All novelty," said Lord Bacon, "is but oblivion. Every phase, theory, and system comes round again as the wheel of time revolves, but he only is the well-prepared observer who can recognise such revolutions and pick out the good while he allows the bad and useless to flow away." This, after all, is but the modern version of the older declaration, "There is no remembrance of former things. The thing that hath been it is that which shall be, and there is no new thing under the sun." I counsel you, then, to read the ancient authors carefully, while you pay chief attention to more modern writers.

This point leads me to dwell for a moment on the inestimable advantage of general literature and a knowledge of the world to the practitioner of Medicine. To none more than he is that wide, liberal, broad grasp of thought and opinion more necessary which is best secured by an acquaintance with the great minds who have illuminated the world by their writings in prose and verse, and who have, thank God! done so much thereby to lighten the burden of that sore travail by which we are exercised here below. If you restrict your attention to your own professional literature your minds cannot fail to become contracted and dwarfed. You will be ever devoured by small and insignificant cares, and occupy yourselves with those petty rivalries and jealousies ("that fume of little hearts") which form the curse of our Profession. It would in a great measure put you above that spirit which is the demon of our day, which loves to speak evil of a brother, to attribute to him false motives, to detract from his success, and sneer at his abilities. This mean spirit comes much from a too sordid devotion to the little arts which promote professional advancement and the neglect of a liberal education. But to return.

By a neglect of general literature you deny yourselves much of the purest and most elevating enjoyment of which an intelligent human creature is capable, and much that would soothe and comfort you amidst the grave anxieties inseparable from your calling. It was a sentiment of Celsus that "the contemplation of nature, though it cannot make a man a Physician, yet may render him fitter for the practice of Medicine," and we may even with more truth affirm that a knowledge of general literature will greatly aid all of you in your calling. When Sydenham was at the height of his reputation, he was asked by Sir Richard Blackmore, what was the best course of study for a medical student, and he replied, "Let him read Don Quixote." I do not assert that the lively adventures of "the Knight of La Mancha" is still the most useful Manual for a surgical student (and I may as well say at once that I do not intend to use it in this class), yet in Sydenham's reply there is the assertion of the same thought I have just been trying to express—*viz.*, not to be narrowed, cribbed, and chained, by a too exclusive devotion to mere Professional studies.

A knowledge of the world, too, and of the ways of men, is of much use to all of us. Richter puts it perhaps rather too strongly when he asserts that "a doctor should have one-third of knowledge and two-thirds '*Savoir faire*!'" but it is unquestionable that "he who best fits his weapon to the mark speeds best." "You have a doctor," said the King one day to Molière, "what does he do for you?" "Sire," replied the wit, "we talk together, he prescribes medicines, I do not take them, and I get well." In our day, when the wear and tear of the mind plays such an important part in our corporeal ailments, when men's nervous organisation is strung to torture in the struggle for existence, it is not by gross drugs and the routine of the schools,—not by looking on and treating the sufferer as a mere disordered machine to be acted on by certain physical agents, that a cure is always to be attained; but, on the contrary, it is often by the perception and remedy of that "mind diseased" which lies beneath and beyond the more apparent bodily ailment. If the members of our Profession were better moral philosophers there would be less irregular practice and fewer adventurers among us than at present.

Gentlemen, I fear I have already outrun your patience; and yet I could say much on the future of our Profession, and on its claims on public estimation. It is in the prevention of disease that we hope to gain most in the time to come—in the tracing out and destroying those causes of sickness of which we have so vivid a proof in that great group of self-propagating diseases which of late have attracted so much attention. It is now well recognized that the most potent germs of death and sickness may be received from air and water, in which neither eye nor chemical test can discover any adulteration; and men are now fully alive to the necessity of most minute examinations of soils, climatic vicissitudes, &c., as bearing on the etiology of disease, and also of experimentally determining the physiological effects of drugs. In our own department of Surgery, as it seems to me, much remains to be done in determining more accurately the origin of surgical disease, in fathoming the influence of diathesis and hygienic surroundings, not only on the progress of such affections, but also on the results of operations, and in simplifying mechanical appliances. Surgery in our day does not hesitate to borrow from each and all of the accessory sciences whatever will throw light upon or aid her researches. Learning on Physiology and Pathology and conversant with Natural Philosophy she pushes on to attain more precision and more usefulness.

Finally, I might say much as to the noble aim and exalted scope of our Profession. It is good sometimes to dwell on such a theme, just as the religious devotee finds his enthusiasm roused and his courage strengthened by the contemplation of a picture of Christian perfection. Some of you may fail in life possibly from no fault of your own, as the race is not always to the swift, but you will have the consolation of forming one of a noble corps which has been ever foremost in the fight waged with the great enemy Death. Unremunerative in a singular degree as Medicine is, and seldom crowned with social honour, it has yet the enviable claim of conferring the most inestimable service not on the individual only, but also on the nation, if it be true that "the real wealth of a nation is the health of her masses," and that "a damaged body is a moral disadvantage." It is, unfortunately, but for a comparatively short period of his life that the medical man can reap any pecuniary benefit from his toil, as neither in youth nor age can he greatly succeed, and, unlike the merchant, his business dies with him, and, in a great measure, his gains cease when sickness, to which his calling renders him so liable, comes upon him. Yet where is there a Profession (the Clerical perhaps excepted) in which scope is so largely given for the development of your whole being? To the very end of your career you can look upward and forward to new fields of research, and to renewed striving after improvement. Your Profession has been called "God-like," and

so it is when rightly judged, as, after the creation of life, we must surely rank its preservation. The object of its solicitude, sympathy, and care is man himself, made after the image of God, and endowed with that nobler part which "owes no homage to the sun." We are fellow-workers with the Divine Physician who "went about healing all manner of sickness, and all manner of disease among the people," and who cheers the sufferer by the promise of a Home in which there will be "no more pain."

To give rest to the weary sufferer; to recall the lost senses and the manifold enjoyments they bring; to reseat the reason itself on its throne, and so restore man to his place in creation; nay, even to snatch a precious life from beneath the very shadow of death, are some of the triumphs to be secured by skill and perseverance; and truly they far surpass all other material conquests.

Viewed aright, then, and practised in a becoming spirit, your Profession cannot fail to evoke your utmost enthusiasm and your greatest energy. To be worthy of it you must strain every nerve and keep the heart pure. "Be assured," said Sir John Forbes, "and believe the words that come from a professional experience of more than half a century, that to be a successful and happy medical practitioner, virtue, a good character, and a kind heart are as necessary as knowledge and skill." A distinguished divine, preaching to young men about to choose a profession, thus spoke: "Surely the practice of a profession, almost every activity of which is a fresh corporal work of mercy, must have an increasing attraction for those who, in the moral sense of the expression, 'seek things above.'

I venture to hope,—nay, to believe—that as public opinion becomes more Christian, a higher, nay, the very highest social consideration will be everywhere assigned to the members of that noble profession of Medicine which ministers with one hand to the progress of advancing science, and with the other daily lavishes its countless deeds of unknown, unacknowledged generosity and kindness on the sick and suffering poor." "He who gives himself," said the great and good Sydenham, "to the study and work of Medicine ought seriously to ponder four things: 1st, that he must one day give an account to the Supreme Judge of the lives of the sick committed to his care; 2nd, that whatsoever of art or of science he has by the Divine goodness attained to is to be directed mainly to the glory of the Almighty and the safety of mankind, and that it is a dishonour to himself and to them to make those celestial gifts subservient to the vile lusts of avarice and ambition; moreover, 3rd, that he has undertaken the charge of no mean or ignoble creature, and that in order to his appreciating the true worth of the human race he should not forget that the only begotten Son of God became a man, and thus far ennobled by His own dignity the nature He assumed; and, lastly, that as he is not himself exempted from the common lot, and is liable and exposed to the same laws of mortality, the same miseries and pains, as are all the rest—so he may endeavour the more diligently and with more tender affection, as being himself a fellow-sufferer, to help them who are sick." True, the claims of our social life demand strenuous labour for the bread that perisheth in the using; but let us ever remember that "a good name is better than precious ointment," and that to fulfil our highest destinies as men we must labour for that meat which endureth unto life eternal. "For," says old Clemens Alexandrinus, "the nourishment of the body is not the work we have to do, nor is sensual pleasure the object of our pursuit; but rather the entrance into those mansions of incorruption where the Divine Wisdom is guiding us."

THE Dialectic Society of the University of Edinburgh has agreed to admit as members, on the usual conditions, all ladies who are matriculated students of the university.

CASE OF SLOUGHING ULCER.

By W. E. C. NOURSE, F.R.C.S., Surgeon to the Brighton Hospital for Sick Children.

On the 7th of March, 18—, I was called at night to a gentleman with hæmorrhage from a sloughing ulcer on the dorsum of the foot. I found a triangular wound, nearly two inches across, covered with a dark green slough, from under the edges of which bright arterial blood was slowly oozing. The whole foot was painful. The patient was over fifty years of age, corpulent, highly nervous, feeble, and tremulous, with a weak pulse, and no appetite; altogether in a state not favourable to any reparative process. Thirteen months previously he had recovered with difficulty from an attack of erysipelas. The present wound had been caused by a blow from the heel of one of his boots, inflicted while pulling it off four weeks since. A lotion of sulphate of copper and opium was now applied beneath an elastic bandage, and he was ordered to take opium and dilute sulphuric acid every four hours.

March 9.—Foot easier; no bleeding; aspect of wound unchanged. To continue the mixture with one grain of quinine every four hours, and take an aperient pill with one grain of opium at night.

March 10.—Appetite *nil*. No improvement. Two grains of quinine every four hours. Wine, or brandy and egg, at intervals.

March 12.—No improvement. Continue mixture and lotion. One grain of opium with one of quinine every night. Aperient pill with one grain of opium every other night in addition.

March 17.—Foot red and painful. No appetite. A very little more sleep at night, but no other improvement. To apply a poultice, continue mixture, and take two grains of opium with five of colocynth at night. Stimulants continued, and all the nutriment possible.

March 19.—Foot less painful. No other improvement. To have three grains of quinine with opium, and nitro-muriatic acid every six hours, and two grains of opium with two of quinine each night. Colocynth pill every second or third night.

March 21.—Slight increase of appetite. Wound no better. Strong nitric acid applied.

March 24.—Improvement at one part of the wound. Acid reapplied to the other parts. Continue medicines and regimen.

March 31.—Very slight increase of appetite. Portions of slough have separated, showing a raw surface with a feeble granulation here and there. About an inch of three of the extensor tendons exposed. To be dressed daily with a solution of nitrate of silver. Continue medicines.

April 7.—Appetite very poor. Wound more sloughy. Acid reapplied. To have a mixture of gentian thrice daily.

April 10.—Appetite quite gone. Wound more sloughy, and with sharp everted edges. Acid again applied. To have five grains of quinine three times a day.

April 12.—Wound cleaner. Some slough removed. Appetite inclined to return, but very feeble. Wound dressed daily with nitrate of silver lotion.

April 17.—Less slough. More granulation. Appetite a little better. Applied a flannel roller with moderate tightness from toes to knee. Enjoined removal from a bed to a chair for an hour or two daily.

April 21.—Improving. Foot dressed every other day only.

April 26.—Wound inclined to close at one part. Feeble granulations elsewhere. Portions of the tendons separating. Applied strapping over the lotion. Moves daily into the next room.

May 2.—One part of the wound again sloughy, with sharp edges. The medicines have been steadily continued, also the stimuli and nourishment, varied as occasion requires. Applied acid to the sloughy part.

May 8.—The wound, which has been dressed daily with nitrate of silver lotion, is cleaner, but is disinclined to heal.

Appetite somewhat better. The quinine, opiates, &c., are still continued. Dressed the wound with a lotion of the liquor calcis permanganatis.

Under the daily use of this lotion the discharge was observed to increase. In a few days better granulations sprung up, and more progress was made than under any other dressing. Still the progress was extremely slow. New skin tardily formed at the edges of the wound. Bits of tendon gradually came away, and the appetite required constant tempting, nor could stimuli be to any extent withdrawn. The opium and quinine were scarcely diminished until the healing of the sore, which took place in August, five months after I was first called to him, and six after the receipt of the injury. The foot and leg being well bandaged, he was encouraged, during the last fortnight, to try and walk. A troublesome attack of unhealthy balanitis annoyed the patient for several weeks at this time. By October he was as well as usual, and walking about.

The tendency of the constitution to low forms of inflammatory action will be noticed. Now, balanitis, following a sloughing wound; formerly, erysipelas. The ulcer, being not the centre of the disease, but rather an expression and a consequence of the unhealthy state of the constitution, and not extending rapidly, appeared to demand principally careful constitutional treatment (liberal support, quinine, opium, periodical clearance of the alimentary canal), and was not likely to be put in course of healing by one thorough application of acid. Several applications of it were made, and each was followed by cessation of sloughing, and by a feeble attempt at granulation. More acid would only have destroyed more tissue (for the repair of which there seemed scarcely power enough) and more of the extensor tendons. This case is, therefore, a contrast to Mr. Adams's interesting case of supra-public ulcer (in a late number of the MEDICAL PRESS AND CIRCULAR), in which the general health was not much affected; in which a single thorough application of acid proved so effectual, and which responded at once to the action of remedies.

Out of about 307 cases of ulcer of the leg or foot (some of them sloughing, others of aggravated character) which have been treated by me during the last ten years, the case now related was among the few tedious and intractable ones, and was the only one that required a lengthened confinement to bed. The patient's system appeared to respond very slowly and unwillingly to any kind of medication. Small doses were as nothing; medium doses effected little; and it was only by large doses, and those constantly repeated, both of quinine, opium, and alcoholic stimulus, that any good could be done, and by persistence in which the case was brought to a successful termination.

THE ANTIDOTE FOR HASCHISCH.

By Professor POLLI of Milan.

As haschisch has been employed as an exhilarating agent, and even as a remedy against melancholia, it is useful to know the substances which can increase or destroy its action.

Experience has proved that infusions of coffee, of tea, and of cocoa, always increase the action of haschisch; so that if it is wished to accelerate or to augment its effect it should be taken or administered in an aqueous infusion of one or other of these vegetable substances.

Lemon-juice and vinegar, and, consequently, citric, malic, acetic, and tartaric acids, in aqueous solution, more or less diluted, arrest the effects of haschisch in a person who has taken it, and thus are competent to serve as real antidotes.

It will then be useful in making a trial of haschisch, and especially in the treatment of certain nervous maladies by haschisch, in cases where one does not as yet know the susceptibility of the subject, to know that one has in the lemonades of these acids, more or less concentrated, powerful, and at the same time innocent, moderators of the nervine action of haschisch.

I confess that it is not from my own personal experience

that I have confidence in the preservative action of the vegetable acids against the injurious effects of haschisch; but solely from the experience of the Egyptians, who have assured me that it always succeeds with them, and from the testimony of Dr. Castelnovo, who lived for a long time at Tunis, where he convinced himself of the antidotic value of lemon-juice and strong lemonades against haschisch.

Hospital Reports.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.

ON a recent visit to this hospital we saw a case of episclerotitis in a young woman, aged 30, a patient of Mr. Critchett's. A small red point was seen on the sclerotic of the left eye, reddish in hue, and of a hard consistence. Mr. Critchett observed that this affection of the sclerotic was peculiar to women, and was connected in them with some derangement of the menstrual function. He pointed out that in the patient before him there was a growth of hair on the upper lip, and on inquiry it was found that she was and had been suffering from amenorrhœa for some years past.

CASE 2.—A woman, aged 30, came to Mr. Critchett with dilated sac and obstructed duct on the left side. She had been married six years, and had borne one child, which was healthy, and of the age of six. Since then she had not had any pregnancies. Mr. Critchett observed that there was ozena, and that in specific cases, like the one before him, it was very difficult to produce much effect by means of operation. For the ozena he prescribed gr. x. of iodide of potassium, *t.d.*

CASE 3.—A young woman, aged 20, came under the care of Mr. Couper on Friday, the 10th inst., with interstitial keratitis of both eyes. There was a patch of exudation at the lower part of the left eye, and a general diffused haziness in the cornea of the right eye. The appearance of the teeth was most characteristic. The two middle upper incisors were thick and deeply notched at the free border; the four lower incisors were thin, and slightly notched also at the free edges. The sight was worse in the left eye than in the right. The patient, who looked otherwise in perfect health, and had a healthy bloom on her cheek, was in a draper's shop, and had never suffered from ill health during her life. Her mother, who had married two brothers, died when she (the patient) was two years old. She has a brother of the age of 23, who is in perfect health. Patient is not deaf, nor are there any other marks of inherited syphilis to be seen beyond the teeth and the cornitis. She had never suffered from dimness of sight until three months before. Mr. Couper said that the history of these cases was often easily made out, the mothers having almost always suffered from dead births, or some other syphilitic symptom about the date of the birth of the patients.

An American surgeon exhibited to Mr. Couper an ophthalmoscope devised by a New York practitioner, consisting of two rings of metal filled eccentrically, in one of which is placed the metal speculum, and in the other a revolving disk, containing a series of little + and — glasses, destined to be set opposite to the aperture in the mirror in cases where the refractive power of the eyes inspected requires the aid of such lenses. Mr. Couper expressed himself much pleased by the ingenuity of the instrument, and intended having one similar constructed by Messrs. Beck.

CASE 4.—Mr. Bowman operated on a case of dislocated lens by extracting the lens. The patient, a man of about 55, had received a blow on the orbit of the right eye, and this had been followed by dislocation of the lens into the anterior chamber. Mr. Bowman, after the patient had been set asleep by chloroform, caused his body to be bent

well forward, so that the head was in a dependent position, and the cataractous lens having fallen into the anterior chamber, he transfixed it with a needle, and then, bringing the man's back into the supine position, with his face opposite the light, he made an incision at the edge of the cornea large enough to let the lens through, and then extracted it without any prolapse of the iris, or without cutting away any of it.

Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

DECEMBER 6, 1869.

PETER MARSHALL, Esq., President, in the chair.

Mr. HAYNES WALTON read the outlines of a case of sympathetic ophthalmitis following five weeks after injury to and disorganisation of the other eye. Two months later the injured eye was extirpated; nothing more was seen of the patient for two years, there was then no acute mischief, the pupil was closed by lymph, an artificial pupil was made, and the patient was able afterwards to gain his living as a messenger.

Mr. SAMPSON GAMGEE then read a paper
ON COMPOUND FRACTURES.

He preferred to our own the French division into simple and complicated fractures, the latter including swelling and wound. A fracture with a penetrating wound may be and often is a less important injury than what is commonly called a simple fracture, though accompanied with much bruising of the soft parts, and consequent swelling. In all cases, if the limb is to be saved, the author recommends adherence to the same principle of treatment, immediate reduction, immobility and compression; soft pasteboard splints are the agents chiefly relied on, but to be efficient they must cover indeed the joint above as well as below the seat of fracture—a principle firmly inculcated by Percival Pitt, who was erroneously held to be the advocate of position against splints. On the great value of pasteboard splints, the sound practical teaching of Jean Louis Petit was contrasted with the fanciful objection of Malgaigne. The fallacy of John Bell's objection, and the use of compressing bandages in fractures were fully exposed and a number of cases were adduced to illustrate the author's practice; amongst them one of compound fracture of the ankle joint, in which complete recovery followed excision of the astragalus and the application of a compressing pasteboard apparatus, only opened for the dressing of the wound once in nine days. Referring to Professor Lister's carbolic acid treatment, Mr. Gamgee said, "Until the distinguished surgeon whose intimate friendship during the whole of my student-ship, I shall deem one of the greatest happinesses of my life, thinks well to publish his views and experience in a collected form, it will not be possible to examine them with that completeness and impartiality which his character and position, no less than the importance and difficulty of the subject deserve; but having read all that the Edinburgh Professor has hitherto published, and having seen his practice, with the advantage of his personal exposition in the Glasgow Infirmary, I do not hesitate to say that, so far as I am able to judge, the practice of introducing pure carbolic acid into the innermost recesses of a compound fracture is a mistake."

An interesting discussion followed, in which Messrs. Hunt, Haynes, Walton, de Meric, Carter, Wm. Adams, and Weedon Cooke took part.

A vote of thanks having been unanimously accorded to Mr. Gamgee, the meeting adjourned.

ARMY MEDICO-CHIRURGICAL SOCIETY OF PORTSMOUTH.

Deputy Inspector-General Dr. GORDON, C.B., in the chair.

Surgeon FRANKLYN, Royal Artillery, read some remarks
ON A CASE OF ANEURISM OF THE AORTA IN THE PERSON OF A
SERGEANT OF THE 12TH BRIGADE.

The tumour connected with that vessel had extended downwards into the abdomen, pressing upon the bodies of the first

and second lumbar vertebrae, and causing the absorption of a considerable portion of them, at the same time that it projected to such an extent backwards in the loins as to threaten to give way. The extent of the tumour where it thus projected was six and a half by five and a half inches, and a point of interest in the case was the circumstance that its subject had been able to continue at his work up to a comparatively short time before his death. Sketches illustrative of the disease were handed round. Assistant Surgeon O'Leary, honorary secretary, read a paper by Assistant Surgeon Murray, R.A., on the advances in surgery during the last quarter of a century. The author alluded to the benefits to surgery due to chloroform, contrasting not only the suffering of patients under operation, but their subsequent mortality prior to and after the introduction of that agent; to local anaesthesia, whether by the application of ether spray as introduced by Dr. Richardson, or congelation after the plan of Dr. Arnott. He proceeded to advert to the operation for ovarian dropsy, first performed in 1823 by Mr. Lizars, of Edinburgh, then for a time allowed to fall into disuse, but more recently revived and now practised by several surgeons of eminence, to the improved treatment of aneurism in accessible situations by pressure, to the resection of joints as a substitute in certain cases for amputation, especially with reference to the knee joint, and in gunshot injuries generally. He referred to the operation of crushing calculi so successfully performed by Sir H. Thompson as a great improvement in the method of treatment as compared to the more severe operation of lithotomy, to the introduction of silver wires in supercession of ordinary sutures; to acupuncture as a substitute for ligatures to divided arteries, and to the treatment of wounds by water and other cleanly applications instead of by poultices and unguents as formerly. He remarked upon the injurious extent to which the administration of mercury had previously been pushed, and the improved system under which that drug is now administered, and concluded by observing that medicine as a science had not in his opinion made such advances as surgery.

A brief discussion followed the reading of the above, and the proceedings terminated.

Inventions.

RICHARDSON'S SPLINT, FOR THE TREATMENT OF FRACTURES OF THE CLAVICLE, SCAPULA, AND NECK OF HUMERUS.

DR. HAYNES L. RICHARDSON, of this city, reports the *New York Medical Record*, has devised a very useful and valuable apparatus for the treatment of fractures in the neighbourhood of the shoulder. It is composed of three parts, and has three points of attachment, viz., to the side, axilla, and arm. The arm and body pieces are semi-cylindrical in shape, and are composed of some flexible but moderately stiff material like leather covering a pasteboard foundation, hard rubber, or papier maché, and are fastened together by means of rivets, with sufficient space being left between them to allow the passage of strips of adhesive plaster. The crescentic pad is received as a crutch in the axilla.

For fracture of the clavicle the crutch is crowded firmly in the axilla, the arm piece secured to the arm by circles of adhesive strap; the shoulder is then raised and the arm carried backwards until the fragments are brought into position, when the body splint and crutch are secured alike by straps of plaster.

For fracture of the scapula the arm is carried forward instead of backwards, before the splint is secured to the side. For fracture of the *humerus* the arm is secured in its most natural and easy position. In all other respects the splint is adjusted the same for fracture of either of the above-mentioned bones. After the splint has been applied, the arm may or may not be flexed at a right angle on the chest, and supported by a sling from the neck.

This apparatus is simple in its construction and application, and differing from all other appliances in not in-

terfering with the opposite shoulder. It is adjusted with great ease and dispatch (*neither rings, pads, nor bandages being required*), and will retain fractures of the above-mentioned bones on either side in position better, and with much greater comfort to the patient, than any other apparatus now in use, and does not need to be readjusted during treatment. It has been used in several cases with entire satisfaction to the surgeon and the patient.

A NEW FRACTURE APPARATUS.

A NEW dressing for fractures of the leg has been devised, according to the *Chicago Medical Examiner*, by Dr. E. D. Kittoe, of Galena, late medical inspector U. S. A., which, on account of its convenience and capability of being made by an ordinary mechanic, is deserving of commendation. It consists of two steel or iron rods, a quarter of an inch in diameter and thirty inches in length. These are connected by a cross-bar at one end, and by two sliding semicircles intended to go over the front of the leg.

A foot-piece of wood sits between the rods, and is suspended to a steel semicircle by a clamp screw, so as to allow of its being turned in any direction, and also drawn to and fro on the rods, which are loosely clasped by the semicircle. The foot of the patient is attached to the board by adhesive straps either passed around the foot itself, or up the sides of the leg. Through the cross-bar at the end of the rods passes a screw ten inches long, which is attached to the foot-piece by a swivel joint. By these means the foot-piece is drawn down, making extension with any desired force. The counter-extension is made by two broad thick pads, attached near the upper extremities of the side rods by clamp screws, so that they can be adjusted to any necessary length. These pads press against the bulge of the tibia on each side, just below the knee, and may be fitted to variable sizes by extemporized pads placed under them, thus making effectual counter-extension. The limb is supported between the rods by passing a bandage to and fro beneath it exactly in the manner of Smith's Anterior Splint; and the whole is then suspended by a branched cord to a hook in the ceiling, or to a wire arch under the bed-clothes. The branched cord is of course attached to the two sliding arcs which attach to the rods.

The only cases where this splint cannot be used would seem to be those in which there has been contusion about the knee, so that the patient cannot tolerate the pressure of the counter-extension pads; but even in these cases it would have all the advantages of Smith's Anterior Splint, while in all other cases it adds to the merits of Smith's apparatus the benefits of perfect extension and counter-extension. It is a great comfort to a patient to have the free motion of the limb allowed by suspension, without losing the advantage of extension, or risking the displacement of the bones. Both these objects are gained by Dr. Kittoe's apparatus.

Literature.

THE CONTAGIOUS DISEASES ACT.*

THERE is great interest evinced by a large section of the Medical Profession in the extension of the Act called the Contagious Diseases Act of 1866 to the civil population. Only a few in our ranks have as yet protested against this experiment; and among the few we have to notice the name of Dr. Chas. Bell Taylor, of Nottingham, who, in a pamphlet

* Observations on the Contagious Diseases Act, showing how the new law debases women, debauches men, destroys the liberty of the subject, and tends to increase disease. By Charles Bell Taylor, M.D., F.R.C.S.E., Nottingham: Banks, 1869.
The Cure of the Great Social Evil. By F. W. Newman, Emeritus Professor of University College. London: Trübner.

of sixteen pages, wages battle against the ideas of Mr. Skey and the Admiralty Commission in a very telling manner. Dr. Taylor quotes from the Blue Book to show that women are sometimes falsely accused of being prostitutes. Thus, Mr. Parsons, one of the Surgeons under the Act, is asked by Dr. Brewer how he knows that women not prostitutes have been brought to him, and replies, "I know one instance of my own knowledge, by my happening to know that the woman was a respectable married woman." The women, it appears, sometimes keep coming up for examination, in order to avoid losing their character by being brought up before a magistrate; and it seems that the police, when they see a woman out at night, are very apt to suspect that she is a prostitute. Mr. Parsons adds that he has not had many cases of virtuous women thus insulted. Bravo! Mr. Parsons, and bravo! the law-givers, who only make felons of all the prostitutes, and don't insult many other women. It certainly is an advantage to be born a man. One fact mentioned by Dr. Taylor is worthy of note, and that is, that last Session a Bill to extend the provisions of the Act of 1866 was quietly passed through the House at the fag end of the Session. This was certainly a shabby proceeding. A rather telling argument against the wholesale examinations carried on at Woolwich and elsewhere is the fact that syphilis has been more than once communicated by drinking vessels, and, *à fortiori*, it may be certainly conveyed by the female speculum in such examinations, as 150 women are sometimes examined in two hours in Paris. Then Dr. Taylor truly says that true syphilis is sometimes communicated by persons who have very few traces of the disease in their own persons, and at the Dreadnought Hospital this has been found to be the case. Some discharges are contagious, others not; and are we to keep a woman in hospital for months because she has a uterine catarrh, which may not be infectious, or, if so, would only communicate gonorrhoea? The most telling of all arguments against the Contagious Diseases Act extension is quoted from Dr. C. Drysdale's remarks in the MEDICAL PRESS AND CIRCULAR, where that gentleman asserts that there seemed to him to be rather more cases of syphilis in Paris than he was accustomed to see in London Hospitals. Dr. Taylor also points to the fact that the police of Paris often insult ladies and other women by taking them for prostitutes. "Many a time (he says, with indignation), when I have witnessed the arbitrary interference of the Agents de Mœurs, in Paris, with all classes of females, have I said with honest pride, 'Such a villianous system would not be tolerated in England for a day.'" A couple of drunken sailors, says Sneller, of Utrecht, will infect twenty women in a week. Gonorrhoea, pseudo-syphilis, and syphilis are three diseases of very different gravity; and Balfour is reported to have said he was quite prepared to say that the Act was not successful in reducing the amount of true syphilis, which is the great thing we wish to do. Dr. Taylor shows that, if free hospitals had been opened, quite as much good would have been effected without any tyrannical dealing with women's liberty. Finally, Dr. Taylor shows that the amount of contagious diseases is slightly on the increase again in Woolwich, Aldershot, Chatham, Sheerness, Portsmouth, and Devonport. Hence he asks a verdict against the Act on several counts. He also adds that many married men, who before had been contented with home indulgences, have now, trusting to the illusory powers of the State to secure "clean prostitutes" for all-comers, gone astray and contracted syphilis.

Mr. F. W. Newman is well known as a vigorous, although rather intemperate, writer—often right, but not unfrequently wrong, after the manner of clergymen and literary men, in the object of his invectives. In this case, however, as he is on the same side as Dr. Taylor, we quote his ideas with pleasure. He quotes, with approbation, from a paper by Dr. Gourley, read at the Social Science Meeting at Bradford, where he showed that the soldier is entrapped into the army by making him drunk, then kept in artificial idleness, in wretched ennui for eight hours a day. Mr. Newman protests against the idea that prostitution must be accepted as an English institution. Alluding to the stealthy way in which the Act passed through Parliament last Session, he says there is great danger lest, by such stealthy extension, they gradually get into their grasp the women of the whole country. He has not heard the name of a woman who does not regard the Act with intense aversion. "No plebeian Parliament would ever have passed (says Mr. Newman) so disgraceful a law." If a woman whom the chief of the police tells the justice he "has good cause to believe" is a prostitute, refuse to submit, or to reappear stately, she is liable to prison with hard labour, first for a

month. She has no jury, no counsel. She shall *not* nourish the hope of getting back into honourable ranks. If you accustom her to it, do you expect her ever to recover modesty? Will not this tend to extend disease? The Parisian women become very abandoned, every one knows; and prostitution is far more extended in Paris than in London, because of this brutalizing law.

It appears that a private International Society of Ladies is rising on the Continent to put down the Continental system. Speaking of soldiers, Mr. Newman remarks that, once enlisted, the kidnapped men forfeit every vestige of English liberty. They are kept in constrained idleness, and turned into boys and puppets; few of them are allowed to marry. Prostitutes are regarded by many commanding officers as the natural and necessary complement to the camp and barrack. The great mass of men in the ranks here and on foreign stations are periodically examined. But the Act is silent with regard to male civilians. "No epithet of scorn and hatred can be too strong for the dastardly favouritism of the male sex. . . . Set the spies on *men*; take evidence from the harlots themselves against *men*. They would quickly point out grey-headed fathers of families, surgeons, or now and then a clergyman, who frequent brothels and seek their company. . . . Legislators are tender over their own sex. . . . We should need female magistrates to hinder such a law from being a dead letter." Despotism is sometimes necessary, as in the case of battle or of pestilence; but it should be impartial. He points with scorn to the argument that women should be kept clean, because married men frequent them. This should be a reason to arrest, cleanse, and punish the family men, rather than the prostitutes. Finally, he quotes from the Report of Mr. Simon, that this Bill should be called by its correct name—"A Bill for warranting a woman clean to those who wish to use her."

Summary of Science.

By C. R. C. TICHBORNE, F.C.S., M.R.I.A., ETC.

[The Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

NAPHTHALINE.

NAPHTHALINE was, at one time, a source of trouble to some manufacturers. It has, however, lately been applied to dyeing and other purposes; and the following information obtained from the *Journal of Applied Chemistry* and the *American Journal of Pharmacy* is of considerable interest. The pure naphthaline when fused is similar to alabaster in appearance, it becomes negatively electric on being rubbed with silk. It melts at 174°, and boils at 452°. Melted naphthaline has the curious property of absorbing a large quantity of atmospheric air, which is given off on cooling. The expulsion is so turbulent, that the naphthaline appears to be boiling. Vohl states that the air so absorbed is very rich in oxygen, and the editor of the *American Journal of Pharmacy* suggests that it is pure oxygen. Indigo is dissolved in this substance with great facility, and forms a dark blue liquid, from which the indigo is deposited on cooling in fine streaks, shining like copper. It dissolves phosphorus, sulphur, iodine, chloride of mercury, arsenious, succinic, benzoic and oxalic acids; also the sulphides of arsenic, tin, and antimony.

Benzoic acid and benzol are thus produced artificially from naphthaline.

The first stage is the production of naphthalic acid. This is accomplished by dissolving 12 parts of naphthaline in 90 parts of sulphuric acid, and carefully adding 80 parts of black oxide of manganese. After the reaction is over, it is boiled with four or five times its volume of water, as long as carbonic acid is given off, the liquid is again diluted with its volume of water, this liquid yields by evaporation sulphate of manganese and naphthalic acid.

When naphthalic acid is mixed with an excess of lime and is submitted to a temperature of 625 to 660° Fahr. it is converted into benzoate of lime. This operation must be performed in vacuo.

Naphthalate of lime (old notation). Benzoate of lime.
 $C_{16}H_4 O_6 CaO + \frac{1}{2} CaO = C_{11}H_5 O_3 CaO + 2 (CaO, CO_2)$

To successfully accomplish this operation requires considerable skill and practice. The benzoic acid is separated from

the benzoate of lime by hydrochloric acid, and with respect to the benzol it can be obtained by subjecting benzoate of lime to distillation with lime. This benzol may serve for the production of nitrobenzol and aniline. (The Editor of this Summary has seen specimens of benzoic acid procured from naphthaline in which the smell of nitrobenzole, or artificial oil of bitter almonds, was very strong.)

TRANSFORMATION OF HYDRATE OF CHLORAL INTO CHLOROFORM IN THE ANIMAL BODY.

According to M. Liebreich, the hydrate of chloral should be transformed into chloroform when coming into contact with the alkali of the blood. The following formula represents the reaction:—

This statement of M. Liebreich has been disputed by several of the French chemists, and in order to set the question at rest, the author of this paper has instituted a series of experiments—partly with fresh blood and partially with live animals, and has also made other experiments. He comes to the conclusion that hydrate of chloral is really split up into chloroform and formic acid, which, however, ultimately becomes converted into chloride of sodium and formate of sodium. (As regards the first part of the decomposition the Editor of the Summary has very little doubt, but he considers the latter questionable.)

CHLOROFORM.

M. Hager states that the chloroform of commerce contains, besides the terchloride of formyle, other chlorinated compounds which are not readily separated therefrom. After the separation of alcohol and water which is invariably present in commercial chloroform, a fluid is obtained which begins to boil at 60° to 61°, and ultimately at 65°. By fractional distillation, it is possible to obtain pure chloroform, which can only be tested by its boiling point and specific gravity. When chloroform is exposed to the direct action of the sun's rays, it becomes decomposed and exhibits an acid reaction. Its principal products of decomposition are hydrochloric acid, chloroxy-carbonic acid, formic acid, and free chlorine. Chloroform is decomposed even in the dark, when air has access to it, but this reaction is very slow. A quantity of from .75 to 1 per cent. of alcohol is sufficient to act as a preservation for keeping chloroform for years, even when exposed to daylight. Chloroform, although it does not exhibit an acid reaction, may still be in a state of decomposition. This decomposition can only be detected by ammonia—which yields a vapour of chloride of ammonium, when brought in contact with it. The boiling point and specific gravity are variously determined by different authors. The *Phar. Austriaca* boiling point 63.5°; sp. gravity, 1.49 to 1.5. Dr. Strecker, boiling point, 61°; M. Limpricht, 62°; M. Biltz, 62.05, sp. gravity at 10.2 C = 1.5085 at 15° C = 1.5020 at 20° = 1.493. The *British Pharmacopœia* gives no boiling point, but gives 1.49 as the specific gravity.

ON THE ECONOMICAL PRODUCTION OF OXYGEN GAS.

Five hundred pounds of manganate of soda are placed in a retort, and superheated steam passed over it, in five minutes all the oxygen is extracted from this salt. This quantity yields two and a half cubic yards of oxygen every hour. Hot air passed over the residue for five minutes restores all the oxygen given up. Six hours' work in this manner, or six extractions of oxygen, and six reoxidations, give 15 cubic yards of oxygen. This oxygen as it issues from the gasometers contains about 15 per cent. of nitrogen, but by letting the first portion escape, the quantity of this mixture can be reduced to 2½ per cent. M. Tesseis du Mothary affirms that one ton of manganate will yield 100 cubic yards of oxygen daily for a year without removing the salt once.—*For. Corres. Chemical News.*

LITHARGE.

Dr. Wittstein has found as much as 1.25 to 3.10 per cent. of lead in litharge in a finely divided state. Pure litharge dissolves freely in acetic acid, the lead being insoluble.

EATABLE CLAY FROM JAVA.

The following is the analysis of this clay procured from Berbek Kediric. It is sold in the market for edible purposes. Silica 39.711, peroxide of iron 9.806, alumina 25.939, lime 3.029, magnesia 1.352, protoxide of manganese .591, potash .572, soda 3.853, water and volatile matter including .506 per cent. of ammonia 14.801; of this material 72.79 per cent. is insoluble in hydrochloric acid. It is a pity that the infor-

mation is not more explicit as regards the 14.801 per cent. of organic matter, in which, no doubt, the dietic value, small as it is, mainly resides.

ON PRODUCING A HIGHER TEMPERATURE IN SOLUTION BY STEAM AT 212° FAHR.

Mr. Spence in a long communication to the *Chemical News*, points out the following curious fact: In a solution of nitrate of soda placed in a vessel surrounded by a jacket, steam was let into the intervening space, until a temperature of 212° Fahr. was obtained. The steam was then shut off, and an open pipe immersed in the solution, and steam from the same source thrown directly into the liquor. In a few seconds the thermometer slowly but steadily rose, until it reached 250° Fahr. The explanation of this apparent paradox is, that the temperatures of the solutions are in exact ratio of their specific gravities, and have no connection with the temperature of the steam, which never exceeds 212°. The greater the specific gravity, the higher the boiling point, and to that boiling point will ordinary steam raise it.

NEW FEBRIFUGE.

Quino-picric acid is the term applied by MM. Duguet and Perret to a golden yellow substance with a bitter taste, insoluble in water, but soluble in ammonia and alkaline solutions without decomposition. When thrown on burning coals this substance burns off like lycopodium, but does not detonate. It is formed by acting with picric acid upon the alkaloids of the cinchona bark—viz., quinioline, cinchonine, cinchonidine, &c. It is said in round numbers to contain 58 parts of alkaloid to 42 of picric acid. *Cosmos* in speaking of this substance says, that it is of considerable value from a therapeutic point of view, and enables us to economize (by the formation of a definite compound), the quina alkaloids, at present lost in the manufacturing of quina.

SCOTLAND.

EDINBURGH.

THE annual meeting of the Association for the Better Endowment of Edinburgh University was held on Friday last, under the Presidency of the Lord Justice-Clerk. From the Committee's Report it appears that £52,000 had been accumulated for the purpose of endowing Fellowships in the University. Sir Alexander Grant, in his capacity as Principal of the University, stated that, in his opinion, the Fellowships which the Association had been largely instrumental in obtaining have had the effect of raising the tone of scholarship. Professor Lorimer called attention to the fact that as yet there was not a Fellowship connected with the Faculty of Law. Professor Laycock was sorry to observe that Medicine received only £40. Natural science and physical science received £260, so that, with the £40 given to the Medical Faculty, those three applied sciences got only £300, against £1,000 bestowed on learning. He trusted a little generosity would flow in the direction of science.

MR. JOHN MILLER, M.P., has withdrawn the unpaid portion (£750) of his subscription to the Royal Infirmary, Edinburgh, on the ground that he disapproves of the Watson's Hospital site.

BENJAMIN BELL, Esq., F.R.C.S.E., has been presented by the inmates of the Edinburgh Blind Asylum with a gold watch on the occasion of his retiring from active duties as Surgeon to that Institution.

GLASGOW.

JOHN WILLIAM WALKER, Esq., F.R.C.S.E., has been appointed Surgeon-Oculist in Ordinary to Her Majesty in Scotland, in room of the late Dr. Mackenzie, of Glasgow.

AYR.

W. J. NAISMITH, M.B., C.M., L.R.C.S.E., has been appointed Consulting Surgeon to the Ayr Fever Hospital and Dispensary, in room of Dr. Mason.

MEDICAL TOLERATION.

In a former number we had occasion to comment with sincere approval on the intended action of the College of Physicians of London in the matter of Examinations. We gladly hail this step as one of the many “signs of the times” in the direction of medical progress and liberality, and we are incited by it to address a few words to our readers to-day on the much more comprehensive and important subject of Medical Toleration. Speaking in the most general manner, in all the intercourse of man with man—in every sphere of society and life—there is no more becoming quality, none more befitting a civilized being, than toleration. And if we were called on to select, among all the virtues, one which should, more than the rest, speak for the truth of that which has often been denied by philosophers—the real progress of mankind in civilization—toleration is, perhaps, the very one we should be most disposed to fix on. For, turn in what direction we will, do we not find progress and toleration absolutely coincident—nay, more, that the proportion of the one bears the closest of relations to the practical extent of the other? Within certain well-established limits, we hold this to be an indisputable fact. And examples are at hand in abundance. If we turn to the side of Theology, and seek an illustration in such an instance as that of the Roman Catholic Church, at present occupying a large share of public attention, it is quite certain that that communion has never taken toleration for its especial motto. Much rather, and most persistently, has it acted on Bishop Warburton's celebrated dictum, “Orthodoxy, Sir, is my doxy—heterodoxy is every other man's doxy.” Still, no one will say that the Church of Rome is not more tolerant now than in the days of Loyola and the Inquisition; yet, notwithstanding, there will be few to doubt that the Catholic public is [any the less religious on that account, or less sincerely devoted to its own Church and ritual. No. But

one thing has happened to it and to all of us, and it explains the phenomenon at once. We live in the 19th, not the 16th century; and the spirit of the modern world is breathed, more or less, on all men and all institutions. That spirit is absolutely irresistible, and one of its very best fruits is seen in the quality of toleration.

We turn now to our own province of Medicine; and if the virtue for which we are contending be a token of advancement in the more certain walk of Theology, what shall we say of its importance in reference to an art not only so difficult, but so constantly shifting as ours? In Medicine, be it remembered, we have not to do with an “exact science,” and medical proof, as we all know, is not mathematical in character, but dependent on the experience of individual observers. It is true, indeed, that this experience is cumulative, and that medical theory and practice, to be authoritative, should and does proceed upon a large induction of facts. But, with all this, let us be candid with ourselves and fair towards the noble Profession to which we belong. It can well afford to be tried in open court—to be dealt with without flattery. And when we glance at its past history, what kind of picture is it that meets our eyes? From the days of Hippocrates down to our own, we behold a continuous succession of changes in opinion and changes in practice. The fierce wrangles of the dogmatists and empirics, the humouralists, the vitalists, and other doctrinaires without end, are fresh in the memory of all students of the early history of the Profession, in the course of which, as they were all alike egregiously mistaken, it is to be presumed the *odium medicum* would be proportionately violent. We pass through all those phases of opinion from the Greeks to the Romans, and, following the course of the art in the hands of the Arabian physicians, and noting the birth of alchemy and its fruits in the doings, centuries afterwards, of Paracelsus and his school, we arrive in fine, with the development of Physiology, at the really scientific era of Medicine.

These things are noted, in passing, to demonstrate the constant changes of the Profession in the distant past. Have these changes been less in our own modern times? Not less, but a hundred-fold greater—changes vast and ceaseless, yet so familiar to every one that we dare not on this occasion do more than allude to them. And this is the Profession in which, for every one of its legitimate members alike, we are claiming the boon of toleration! A superfluous task, one might think, did not much painful experience demonstrate its necessity. In the first place, it must be plain, we should imagine, to every right-minded man, that in such a Profession as ours, of all others, unanimity is impossible; and, moreover, it is just as undesirable as impossible. Where so much is to be done, and from so many sides, absolute identity of view is so far from the thing to be wished, that, on the contrary, every phase of individual opinion, down to the minutest, according to each competent observer's own point of view, is pre-eminently that which the best interests of medical truth require. And hence the vital necessity for toleration as a fundamental axiom in Medicine, if the Profession is to flourish in the future. Toleration absolutely; but, over and above this, the highest and most constant encouragement to every genuine individual effort, however counter it may run to the usually received opinions of the time. That is what we desiderate for the Profession's good—that, in our opinion, should be the recognized creed of the Profession at large. We would seek to regard this sub-

ject from a lofty and generous point of view, and, laying aside egotism and self-esteem, we would welcome every true workman whatever, and honour him for every particle of fresh truth it might be his lot to bring into the common stock, however it should clash with our previous convictions. That, we are persuaded, is the true spirit to advance the Profession of Medicine. At the very outset, let us release our students from the Schools, not as believers in us and our particular teachings, but simply as soldiers of the truth; and let us rather impress on them the motto as they depart, "*Nullius addictus jurare in verba magistri!*" We do not make the faintest pretensions to prophecy, but every one must feel that we have entered on a period of amazing progress in all the sciences, Medicine among the number, and that, great as this has already been, "the greatest is behind." In surveying this vast intellectual country, with all its mighty monuments, we seem to hear the advancing tramp of mightier achievements still, attended, most assuredly, with the overthrow of many venerable dogmas in Medicine as elsewhere; and, in thinking of this, we smile to find ourselves pleading for Medical Toleration.

Notes on Current Topics.

French Hospital and Dispensary.

THE anniversary festival of this charity was held last week at Willis's Rooms, Lord Napier of Magdala in the chair. The Hospital is in the French quarter—Lisle street, Leicester square—and was founded two years ago. Since then it has had 282 in-patients, and 7,643 out-patients. The institution is cordially supported by the King of the Belgians. Mr. Rimmel, the Secretary said the institution had expended £1,000 a year, and that the inmates of the Hospital included patients of eighteen different nationalities. £1,200 were subscribed in the course of the evening. *The medical officers receive, as usual, no remuneration.* In Paris they would be paid.

Highgate Workhouse Infirmary.

THE Guardians of St. Pancras have appointed Mr. D. H. Dyte, who has for several years held the office of Surgeon to the Jewish Board of Guardians at Bishopsgate, to the post of temporary Surgeon to the new Hospital, under the recent Act, at Highgate. We are sure that no more zealous or more efficient officer could have been elected to this important post than Mr. Dyte. His testimonials are of the very highest kind, and he bears with him to his new and important duties the best wishes of his many friends and his former teachers of the London Hospital. We trust that his appointment may be a permanent one.

Abolition of University Tests.

Two deputations in favour of abolishing University tests waited on Mr. Gladstone last week—one from the Universities of Oxford and Cambridge, and the other comprising representatives of various nonconformist bodies.

Blackheath Mendicity Society.

THE system of mendicity tickets, it appears, has almost entirely freed Blackheath from professional mendicants.

Tramps and professional beggars will not have anything to do with such tickets. The ladies of Blackheath, however, are fain to give money in some cases instead of tickets, in order to escape from the importunity of some of the more sturdy mendicants. The remedy for the latter state of things would be, of course, as has been suggested, the appointment of a certain number of policemen in plain clothes to take up such cases.

The Surgeon in Ordinary to the Queen in Ireland.

By a printer's error, the correction of which was overlooked last week, the official rank to which Her Majesty has been pleased to appoint Mr. Porter was incorrectly stated. For the first time the appointment of a second Surgeon in Ordinary to the Queen in Ireland has been made, and, in the person of Mr. Porter, the compliment has been paid to Ireland of placing its Medical Profession on a level in this respect with Scotland.

In the absence of those substantial honours which it is almost the exclusive privilege of the Law to enjoy, it is, we think, to be regretted that professional rank and merit do not more frequently receive even the unrewarded recognition which they deserve. The public mind is being rapidly educated up to appreciation of medical services, and in the future, we venture to hope, to the conferring on the Profession of some share in the emoluments with which lawyers and soldiers are absolutely burthened.

Unlicensed Doctoring in America.

AN inquiry which has been recently held into a case of poisoning reveals a condition of medical morality in America from which, we would hope, we may claim exemption on this side of the Atlantic:—

"The 'Galler Mystery,' as it is called by the daily newspapers, is developing some remarkable circumstances concerning the qualifications of irregular practitioners in this enlightened city. First we had the accused Wedekind, whose claims to a medical title were founded upon a certificate from a dispensary somewhere in Germany, and sundry 'essays' on medical subjects, 'written since he was thirteen years old;' and now appears upon the scene the regular (†) attendant of the deceased Galler, one 'Dr.' Martin Dupuis, who follows his sworn assertion, 'I am a physician,' with the frank admission, 'I have not graduated,' and who appends his mark to his affidavit, being *unable to write his name!* This sagacious individual, it seems, has been practising in New York for nearly eleven years.

"When will the community open its eyes to the fact that dealing with human life is at least as important a business as dealing in merchandise, and learn that its own safety depends on demanding legal protection against ignorance and imposture?"

Spiritualism.

IN reply to a correspondent, the Editor of the *Philadelphia Reporter* recounts his experience of spiritualism, and his reasons for refusing any credence to its *soi-disant* phenomena. He says:—

"We believe that every one of the so-called 'spiritualistic phenomena' is a trick and a deception, or the result of nervous disease. We have belonged to a 'circle' and seen some wonderful manifestations, and after we were completely puzzled, and, like Festus, almost persuaded, the medium has kindly explained some of his most startling

'manifestations.' Last year we agreed to pay the expenses of a medium from Chicago to this city, and add a *douceur* to boot, if he would perform in the Pennsylvania Hospital, before several eminent physicians of this city, what he wrote us he could perform. He came, tried, and—*failed*, in several separate trials. We kept our money, and he—his peace. We here and now make the same offer to any medium in America. But there must be no under-the-table or in-the-dark manœuvres. A fair field, no favours, and expenses paid are what we offer. Who'll try his (or her) hand?"

The New Military Barracks in India.

ACCORDING to accounts received from India, an impression seems to be entertained that the recently erected barracks, according to plans approved by the Sanitary Commissioners in this country and at Calcutta, by no means possess the sanitary advantages that were anticipated from them. They are said to be needlessly capacious, to be hot in summer and cold in winter, and, moreover, to be uncomfortable as quarters for the soldiers, and to altogether fail in adding to the health standard of their occupants. The vast cost of their erection is by one set of financiers considered to have contributed in no small degree to the present deficit in the Indian Treasury, and it is understood that orders have been issued to suspend the further construction of such buildings.

We wait for further particulars. Meantime, we would express a hope that the reports which have reached us are premature, as every person who has spent any considerable time in India must be well aware of the evils to health that arose from the miserable barracks in which, until lately, our troops there were accommodated, as contrasted with such lofty and airy barracks as exist, for example, at Fort William, Chinsurah, and Birhampore.

Death of Dr. A. Bryson.

WE have to announce the death of Dr. A. Bryson, which took place on the 12th inst. at the Heritage, Barnes. This eminent officer, who was a Physician Extraordinary to the Queen, entered the Royal Navy in 1827, and served on the north coast of Spain during the Carlist insurrection, and gained considerable credit from the late Lord John Hay and from Sir Sydney Dacres, to the latter of whom he was specially attached. Dr. Bryson's death was very sudden: he was struck down by a fit of apoplexy on the 10th inst., and lingered until the 12th, on the morning of which he expired. He obtained the position of Deputy Medical Inspector of Hospitals and Fleets 1st March, 1854; and, from his zeal in the service and remarkable energy, he became Inspector-General in June, 1855. His thoroughly energetic habits led him to be appointed Director-General of the Medical Department of the Navy on the death of Sir John Liddell, K.C.B. He retained that appointment until a few months back, when he was succeeded by Dr. Alexander Armstrong, C.B. The late Dr. Bryson, for his civil services to the Navy, was nominated a Companion of the Order of the Bath in June, 1865. He was a Fellow of the Royal Society, to which body he was elected 1st June, 1854. There is no doubt that, through over-anxiety in his official position, he overtaxed his mental capacity. He was much beloved by his friends. The deceased gentleman began his studies in Edinburgh. He also studied in Glasgow, where he took his M.D. degree, and was admitted a Member of the

Faculty of Physicians and Surgeons, Glasgow. He was also a Fellow of the Royal College of Physicians, London. Dr. Bryson had seen a great deal of active service, and was well known as the author of works, "On the Climate and Diseases of the African Station;" "Epidemics of Sierra Leone;" "Statistical Reports on the Health of the Navy," &c.

Health of Napoleon III.

The editor of the New York *Spirit of the Times*, in writing from Paris, gives the particulars of a professional interview with Dr. Brown Sequard. In the course of the conversation, Dr. Brown Sequard directed Mr. Wilkes' attention to a series of articles which had recently appeared in a French paper on the subject of the Emperor Napoleon's health, and which had created considerable sensation. Dr. Brown Sequard stated that the articles to his knowledge had been written by a man who had once been the Emperor's physician, a man of great ability, but dissolute habits, who had lost his standing in society and his official employment, but who nevertheless knew the Emperor's constitution well. This unworthy physician has violated all professional obligations, but, as Sequard insists, has nevertheless told the truth in disclosing the secret that the Emperor Napoleon is suffering from an incurable disease, fungus of the bladder, which must soon, and certainly within six months, put an end to his life. The Emperor, according to Sequard, has doubtless been made acquainted with his fate, and is preparing for it as well as he can. It is further stated that the reason why these articles have not affected the Bourse is that they appear in a bitterly Radical paper, and are not believed, and that the opportunities for observation possessed by the author are not generally known.

Liability of Consulters for the Fees of Consultees.

THE City and County of Cork Medical Protective Association have held an important meeting with the view of deciding the custom of the profession in this matter. Dr. Armstrong, the Honorary Secretary, received the following requisition:—

To Charles Armstrong, M.D., Honorary Secretary Cork Medical Protective Association.

DEAR SIR,—We, the undersigned, request that you will be so good as to convene a *special* meeting of the Association for Saturday, the 27th inst., at four o'clock, to receive from Dr. Townsend a communication of importance to the profession.

(Signed) EDWARD R. TOWNSEND, M.D.
J. R. HARVEY, M.D.
THOMAS GREGG, M.D.
WM. JACKSON CUMMINS, M.D.
E. R. TOWNSEND, Jun., M.D.
NICHOLAS GRATTAN, M.D.

Cork, November 23, 1869.

A *large* meeting, consisting of medical gentlemen, not only from the City but also the County, was accordingly held, which was opened by the President of the Association, Dr. Harvey, calling on the Secretary to read the requisition convening the meeting, whereupon—

Dr. Townsend stood forward, and mentioned the fact of his having, by request of a family, by one of whom he was professionally engaged, telegraphed for the immediate attendance of Dr. ———, the latter holding him, Dr. Town-

send, responsible for the payment of his fee. Dr. Townsend now sought the opinion of the Association as to his liability for the fee, and considered it a question about which the Profession should have a clear understanding, and observed that the fee was of no importance to the patient's friends, who were only ready to pay it.

Dr. Beamish quite agreed that this subject should be distinctly understood from the fact that he, under similar circumstances, had telegraphed for the attendance of Dr. —, who, on visiting Dr. Beamish in his study, at once asked if Dr. Beamish had made arrangements for his fee, the latter replying that the family were able and willing to remunerate him, and that he, Dr. Beamish, left Dr. — to settle the matter of his fee with the patient or his friends.

Drs. O'Flynn, jun. and Cummins argued that the question was too important to be decided by the Association, and suggested that a medical meeting of the entire City and County should be convened to consider it. It was, however, proposed by Dr. Beamish, seconded by Dr. Wm. C. Townsend, and carried,—

"That it is the deliberate opinion of this Association that this meeting is perfectly competent to decide the question now brought forward by Dr. Townsend."

It was subsequently moved by Dr. Shinkwin, seconded by Dr. Gregg, and unanimously carried,—

"That it appears to this meeting that the establishment of a precedent, which would render the physician or surgeon, who may call in another in consultation, responsible to the consultee for his fee, would not only be unjust, but injurious to the interests both of the Profession and the public."

Instructions were given that this resolution be published in the advertising columns of the MEDICAL PRESS AND CIRCULAR.

Dr. Johnston, of Middleton, Co. Cork, mentioned similar cases of telegraphing with which he, from time to time, had to do, and proposed,—

"That the thanks of the meeting be given to Dr. Townsend for bringing this subject before the Association."

Which was seconded by Dr. Purcell, and passed by acclamation.

The proceedings then terminated.

A Cheap Way of Doing the Doctor.

THE "*lene tormentum*"—the gentle violence of railway travelling—appears still to cause disease, and, we suppose, always will. The following advertisement, clipped from the *Times* of Wednesday, seems a cheap move to obtain gratuitous advice.

TO RAILWAY TRAVELLERS.—A gentleman, having suffered some inconvenience to the nervous system by continuous railway travelling, is desirous of ascertaining of any railway traveller having been similarly affected, if any remedy has been found, so that travelling may be resumed with impunity.—Address, &c., &c., &c.

A great deal depends upon the nature of "the inconvenience to the nervous system." Still, granting that X. Y. Z. will receive numerous replies and methods of treatment, from the application of sliced white lily roots to the spine to other forms *ad infinitum*, we would suggest to the advertiser that, although it may be a cheap way of doing the doctor, it may be the dearest in the end to the patient. We hope that X. Y. Z. will confide his case to a physician of repute.

The Welsh Fasting Girl.

THIS case has concluded as every rational man must have foreseen. Medical men know well enough that similar cases often crop up, which belong either to that class of impostors who, by artful contrivances, supply themselves with food while protesting their fast; and those who, from mental or physical disease, take but little food, and that at long intervals, eventually succumbing to nature.

In the present instance, the head nurse (sister Naaman) insisted upon the following conditions, before undertaking the task of watching:—To be allowed to choose her own assistant nurses; the girl's bed to be re-made in her presence before taking charge; her relations not to approach beyond ordinary speaking distance at the bedside; no one to be allowed to kiss her, lest a chance might be given to convey food by the mouth. The watching was carried out with commendable zeal, and yet kindness to the sufferer. Clearly, any watch to be worthy of absolute credence, must be rigidly enforced, and the conditions executed were just and sensible. The result the profession and the public already know.

THE East London Children's Hospital has received a donation of £1,000 from "H. G."

IT is said that four men have died of Asiatic cholera almost suddenly at the Moscow Railway Station.

THERE is to be a Workman's International Exhibition in July, 1870, at the Agricultural Hall, Islington. We wish it every success.

TWO new wards have been erected in the rear of the Fever Hospital, Islington, capable of holding 60 patients, with an allowance of 2,000 cubic feet of air to each.

SIR JAMES SIMPSON has been summoned from Edinburgh to attend the Duchess of Argyll at Inverary. The Duchess seems to have had an attack of an "apoplectic" nature.

THE *American Journal of Syphilography and Dermatology* is the title of a new quarterly journal to be issued on the 1st of January, 1870, and devoted, as its name implies, to the consideration of all venereal and skin diseases. It is to be edited by Dr. M. H. Henry.

SCARLATINA MALIGNA is at the present time epidemic at Eastfield Forest, a populous village between the towns of Mansfield and Sutton. Four deaths are registered this week from it, and a great number are at the present time under treatment for it. Typhoid fever, which has been so prevalent at Sutton, appears in abeyance, only two deaths being returned last week.

THE *Daily News* of the 15th inst. reports another case of death from starvation. A poor woman, aged sixty-nine, a needlewoman, received 2s. 6d. a week from the parish, and 2s. 6d. a week from a relation. She paid 2s. a week for rent. She had died from want of sufficient food. Why was she not taken into the workhouse, according to the law?

THE new Government Lock Hospital erected at Chatham for the use of patients from that garrison, Sheerness, Maidstone, &c., is now completed, and it is expected that it will soon be brought into use, when the Lock patients will be removed there. The hospital has been erected to carry out the provisions of the Contagious Diseases Prevention Act. The chief medical officer for this hospital is Surgeon-Major T. H. H. Baxter.

WE are informed that Dr. Elizabeth Blackwell is established in London with the view to the practice of medicine. Miss Blackwell, we believe, is the first Englishwoman who has taken a degree in medicine. Her diploma, was derived from the College of Geneva, in the State of New York. She studied in Paris, and in London at St. Bartholomew's Hospital. We hear, too, that Miss Garrett's time is fully occupied as a successful practitioner of medicine.

THE *Edinburgh Medical Journal* says that the prospects of the Medical Schools of Edinburgh for this session are better than usual, the number of students already entered being greater than the whole number registered at the commencement of last session, the increase in those matriculated for the first time at the University alone amounting to about forty to the present date (20th November).

WE hear that Dr. Constantin James, a Paris physician, has been nearly murdered in a train on the Paris and Mediterranean Railway. The assassin entered the carriage when the doctor was sleeping, and struck him several blows on the head with a life-preserver. The train, by good luck, stopped at a station where it was not expected to do. The murderous ruffian escaped. Dr. James was much hurt, but his wounds are not considered to be dangerous. He returned to Paris.

MEDICAL journals would appear to enjoy no special privileges in France preferential to the general press. The *Gazette Hebdomadaire*, published last week a warning which it had received from the Government, relative to articles published in its columns on the discussion relative to infant mortality—these articles touching, according to the views of the Government, on matters of political and social economy, forbidden to be discussed in unstamped periodicals. The *Union Médicale* congratulates the *Gazette* on having escaped with a warning, for it had itself been less fortunate—six weeks ago a fine of 52 francs was inflicted on it for the publication of an article by M. Briesse de Boismont in reference to the law of lunatics.

Readers may thus understand and excuse the reserve and timidity of these journals on questions which are the subject of universal discussion.

THE *Army and Navy Gazette* says that "It is currently reported that the Royal Hospital, Kilmainham, Dublin, will, after the 1st of April next, be converted into barracks for a brigade of Artillery, and that the in-pensioners will be treated after the same manner as their naval brethren at Greenwich this year. Of course, if Kilmainham goes, Chelsea may be expected to go also." The *Gazette* thinks,

there is every probability of the rumour proving true, and adds:—"Although we are strongly opposed to the idea of the reductions being allowed to interfere with our old and time-honoured associations, still, in the case of Chelsea and Kilmainham, the country is called upon to provide for an expensive staff of officials, whereas, no doubt, the greater part of the veterans would be better looked after and far more happy and comfortable were they allowed to spend the remainder of their lives amongst their friends or where they pleased."

THE *Philadelphia Reporter* publishes the particulars of a most extraordinary accident, which, coming from a less reliable source, we should have discredited. The Editor writes:—

"Yesterday we went on board the English ship *Tyril*, now loading with cotton here, to see a piece of human bone, two inches in length, which had been driven into the solid oak deck.

"About a month since a sailor fell from the topsail yard, at a height of 120 feet, struck his thigh on the capstan in his descent, fractured his thigh at the middle third, thrust the lower extremity of the upper fragment through the muscles, and immediately afterwards into the deck. After penetrating the oak plank two inches, the bone was again snapped off about an inch above the deck. The bone has been cut off even with the deck, and is now protected by a brass plate and exhibited as a curiosity.

"The most remarkable fact is, that the man is a patient in hospital, and is apparently recovering without other defect than shortening of the thigh about three inches."

INDIAN TRANSPORT SERVICE.—The Indian Transport Service, which is kept up at great expense, does not seem, if we may judge by the complaints brought under our notice, to give much satisfaction to the military officers whose lot it was to pass a fortnight on board between Suez and Bombay. It is credibly reported to us, for instance, that an officer, on seeking his berth, found the slops had not been removed for many days; that he had to make the best of a cabin having a borrowed light; and that the thermometer in this delightful asylum rose to 108 deg. We learn that an officer may sleep on deck, but that no bedding whatever is allowed to be transported to that airy and sacred place. Another, and no slight annoyance, is caused by the regulations respecting the morning cup of tea, so refreshing and so needful. It seems that rigid orders prohibit tea in the cabins. Although the services of the ship's stewards are monopolized by the naval officers, yet the soldier's servants might, without any infraction of the dignity of the royal navy, be allowed to carry tea to their masters. Perhaps it is good for the health of the officers that they are allowed only one glass of beer and one pint of sherry, although they may have more beer at the rate of sevenpence a glass; but it is a vexatious rule which compels a man to drink his pint of sherry at dinner, or not at all. The grievance involved in the disposal of quarters rests on more solid grounds. It appears that the first persons considered on board—at least, one of the transports, after the ladies, are the officers of the ship. Gallantry not being quite extinct, the ladies come first, but when they are provided for, the naval gentlemen next look after themselves, and allot to the military men what are concisely described as "leavings." And this in transports, kept up not for the navy, but the army! One thing we are glad to know—that the soldiers, their wives and their children, are made really comfortable. —*Bombay Gazette.*

Correspondence.

LARGE FAMILIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—There appeared no less than five letters in your impression of December 1st on this topic, which evinces, I am delighted to see, much interest in it among my learned brethren. The subject is so fundamental in the scientific treatment of hygienic topics, that no person, I conceive, ignorant of the question, is fit to treat of the theory of epidemics, &c., without reading it up. I fear I have not been very explicit in my remarks, or have been wanting in rhetorical art in some of my expressions, for I find some of your esteemed correspondents asking me all sorts of curious questions, which I should never have thought it necessary to import into this matter. For instance, had it not been for a Liverpool correspondent, and for Mr. Nourse, I never should have thought of speaking about the dogmatic utterances of any creed. My sole wish has been to examine scientifically whether Mr. Malthus, Mr. J. S. Mill, Dr. Chalmers, and the school of political economists of this time, were or were not correct in attributing the terrible mass of poverty which surrounds us to the over-rapid multiplication (*i. e.*, large families) so commonly witnessed in this country and in Germany. I don't think any of the writers on the subject in the MEDICAL PRESS AND CIRCULAR have point blank denied my assertion that the race of which we are members has a tendency to double itself in considerably less than thirty years. Just let us suppose that women did in this country as they do in Hindostan—marry at the age of puberty. From puberty to the menopause there are thirty years of child-bearing, and it is easy to see how very rapidly our race *tends* to increase if supplied abundantly with food, by considerations of such a nature as this. Giving two years to childbirth and lactation, a healthy woman might easily have at least fifteen children; and we know as a fact that some women who marry early have as many as from twenty to twenty-five children. After this it will not require much evidence to show that in some new countries, such as the United States, the population *has* doubled in some cases in less than twenty-five years—*e. g.*, from 1790 to 1815, not counting immigrants at all. And if this be conceded—and I really wish some one of your correspondents would try to deny it before he goes further—is it not a logical sequence that, unless we take some miracle into account, the population of this country would also double in twenty-five years if it were not kept down by want of food, &c.?

I believe almost all of your correspondents are more or less convinced that we *can* breed very rapidly, and that we must either increase slowly or not at all, like the French, or be half-starved because of the pressure of population on subsistence. Well, if this be admitted, I cannot see why we should not look the matter fairly in the face, and ask, What is the *least disagreeable* of all the ways in which population can be prevented from increasing too fast? And if this aim were kept steadfastly in view, I do think we should not find persons any longer using such hard words in speaking of the views of any writer who tells us what he thinks best. I may at once say that it would have evidently been far better for us had Nature been so arranged as to allow of us doing as we pleased in this matter. But Nature in this case, as in many others, is not studious of our happiness. The fact is, I apprehend, we have only a choice of evils if we remain in Europe. If persons here marry early, and have large families, on an average they must suffer from poor living, which causes many diseases, or their unfortunate children will be cut off by rickets or exanthemata, &c. If Mr. Malthus's plan of late marriage is resorted to, many other evils will arise—for example, prostitution will be common, and wide-spread melancholy, resulting in both sexes, although more especially in the male, in perverted habits which are so frequently—as we learn from our friends who attend to the insane—seen in lunatic asylums, and are certainly in many cases the causes of fatuity. I cannot help thinking, on considering all these things, that any person of sense must be tempted to consider the French plan of small families as much preferable to these. The thoughtful will, of course, understand that it is their *duty* not to lower wages by breeding too fast; the rest may be persuaded, by

considering that a small family is less of a burden to them, and more likely to conduce to the happiness of the parents.

I remain, Sir, yours, &c.,

CHARLES R. DRYSDALE, M.D., M.R.C.P., F.R.C.S.
99 Southampton row, London, W.C.,
Dec. 17, 1869.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Permit me to take a retrospective glance at some of the things that have been said in your columns on this subject.

"A Layman" argues that, as "sexual intercourse must have been designed for the exclusive purpose of procreation," it ought never to be indulged in except for that object, and that when it is, the result is no better than self-pollution, and leads the way to the procuring of abortion, and even to infanticide. This may well be called the large family doctrine, since it would proscribe copulation in all circumstances adverse to procreation, such as during the whole of the interval between conception and delivery, as well as during the ten days preceding the menstrual period, during which intercourse is, it seems, unfruitful. I would beg to be allowed to ask "A Layman" whether he practises what he preaches, and if not, whether he thinks it honest to attempt to lay a burden on others which neither he nor they are able to bear.

"Physiologist" quotes a passage from a medical work in order to show that it is possible to subdue the sexual instinct, and to do without indulging it, or with only a very moderate indulgence of it. But the former alternative, implying, as it does, abstaining from marriage, has nothing to do with the question of large families, which is one that relates exclusively to married people. The latter alternative—namely, moderate sexual indulgence—unless the moderation were of that special kind which would limit intercourse to a particular period, when it is said to be unfruitful—could have no influence in limiting the number of children in a family, but rather, perhaps, the very contrary effect.

Mr. Nourse's genial utterances would seem to me to be directed rather to the subject of the rational exercise of the sexual organs than to that of the regulation of the number of births in families. The moderation which he inculcates, and the restraints which he shows to be incidental to normal married life, must be admitted to be beneficial to the welfare of married people, but appear to me, from his own showing, to be calculated rather to secure the procreation, in full number, of strong children than to affect the size of families. I would venture to address one reproach to Mr. Nourse. He has been somewhat hasty in taunting those of your correspondents who may, I presume, be called his opponents, without daring openly to explain the practices to which they allude. If he will take the trouble to refer to the letter signed A. G. L., he will see that this taunt was entirely undeserved.

Dr. Drysdale, in my humble opinion, has, in his communication, regarded the question too exclusively from a political economy point of view, and as depending on the doctrine of Malthus. The call that there is in certain circumstances for the voluntary regulation of the number of offspring is quite independent of the Malthusian doctrines, for it is of importance not only in over-peopled countries, and those tending towards over-population, but in particular families in all countries. The mere sparseness of population in a country will never secure in each and every family located in all parts thereof that accordance between the number of births and the financial means of the parents on the one hand, and the ability of the wife satisfactorily to bear and rear offspring on the other hand, which is often so desirable for the welfare both of parents and such children as are born. Even in a country like Australia, it must occasionally happen that the comfort and prospects of a household are materially diminished by an undue number of births. The voluntary regulation of the size of families is thus a matter of domestic ethics, the adoption of which must be left to the judgment of each several couple, without respect to the state of population of the whole country in which they may happen to be resident. It will never be put in practice except for the sake of the advantages expected to accrue to the particular family in which it is adopted. To look for the self-imposition of any such restraints for the benefit of the community at large would be absurd. But

the Malthusian doctrine would require its general adoption by populations which are outrunning the means of subsistence. Hence, to inculcate it in connection with that doctrine is futile. What is really wanted is to place before the public in this country correct and unprejudiced statements of the actual practical results procured to individual families, as they are to be observed on all hands—for instance, in France, by voluntarily subordinating the number of births to the financial means of the parents and the physical capacity of the wife for satisfactorily bearing and rearing offspring. If these ascertained facts were woven into popular tales illustrative of the working of the system when judiciously carried into practice, the effect would be all the greater on the public mind.

"A Dispensary Doctor" asks, "Will Dr. Charles Drysdale and those who think with him, allow me respectfully to inquire whether they believe the Christian Scriptures?" Following the example of a supereminent Bible personage, the questioned might very well answer this query with another question, and inquire of the questioner whether he believes in the ordeal of jealousy as an institution worthy of having been communicated to man by Divine revelation (Num. v. 14—17, 24—27), or in that article of the Mosaic code by which it was enjoined to put to death the bride whose virginity could not be proved by certain appearances on the Jewish hymeneal napkin? (Deut. xxii. 20—21.) To ask whether a person believes in a complex collection of writings such as the Scriptures, is about as unmeaning and misleading as to inquire whether one believes in Latin literature.

Yours obediently,
AN M.A., F.R.C.S.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As you inserted the extract from the Paris correspondent of the *Times*, I send you another from the same writer, which appeared in the leading journal last Thursday. He now writes as follows:—

"A much esteemed French friend has kindly taken the trouble to read what I recently wrote about child-farming in France, and to send me a few lines of comment on my remarks. He assures me that the sending of children to nurses in the country is no argument against the paternal and maternal affection for them, and that families in easy circumstances usually make the nurse go to them and keep her in the house, instead of sending the infant to her. This is no doubt true, but, unfortunately, the easy-circumstanced parents constitute, it is to be feared, only a minority. It, of course, would be excessively difficult to change a long-established practice of this kind, the more so as the usual association of women in their husbands' business too often prevents them from giving up their time to nursing their children. But the pith of my friend's observations is to be found in the following passage. He says:—

"As to the number of children, and your model family of six, be assured that, if the two firstborn of the family had lived and prospered, the four others would never have been called into existence. They were merely supplementary children, and the number of six was never seriously intended."

"I have no doubt that my correspondent is perfectly right in this, and, that much being admitted, we need not trouble ourselves to seek in the neglect and cruelty of peasant nurses a cause of the very slow increase of the population of France. In the interest of humanity and of the unfortunate infants we may regret the system, but it is not that which keeps the French nation stationary in numbers, since, if some of the children did not die, others would never be born."

This I consider a most important contribution to the debate.

I am &c.,
T. C. D.

Dublin, December 11, 1869.

NITROUS OXIDE AS AN ANÆSTHETIC.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The introduction of the nitrous oxide gas as an anæsthetic has created so much interest in the medical world, that I am anxious to give the Profession the benefit of my limited experience, as far as I am enabled to do it. I therefore send you an account of the first ten cases in dental practice in which I administered the gas in Dublin. Seven of the cases were painless; two experienced a sensa-

tion of extraction, but not amounting to actual pain; and one felt the extraction in consequence of not being under the influence of the gas. In all the pulse was accelerated at first, and afterwards became feeble as the gas took full effect. In none of them was the breathing entirely suspended. Two showed the extreme lividity of features; in the rest but very little change appeared. No sickness was observed, and no headache was complained of by any patient; the recovery was extremely rapid, and all were ready to leave within four minutes after each operation had been performed. It appears to me that the nitrous oxide offers considerable advantages over other anæsthetics, viz.:—1st. Its rapidity of effects. 2nd. Rapidity of recovery. 3rd. There were apparently fewer disagreeable effects resulting from its administration when contrasting with chloroform, ether, or any of the recently introduced agents. 4th. The tastelessness of the anæsthetic. The disadvantages were in some cases the very rapid recovery, and, second, the trouble of preparing this agent, and the difficulties of applying it compared with chloroform or ether; but I have no doubt that these faults will be much decreased when the necessity of its use becomes more generally felt. All authorities are agreed as to the great importance of care in the preparation of the gas. My patients breathe it direct from the gasometer, and I adjoin below a record of cases for the benefit of your readers.

Mr. C., aged twenty-seven. Anæsthesia produced in three minutes. Extracted first upper molar. No pain.

E. D., aged twenty-three. Anæsthesia produced in two minutes. Extracted three stumps—upper. No pain.

Mr. C., aged nineteen. Anæsthesia produced in two minutes. Extracted lower first molar. Slight sensation of its extraction.

Mr. S., aged twenty. Anæsthesia produced in two and a half minutes. Extracted second lower molar. Painless. This tooth was excessively tender, and the patient could scarcely bear it touched.

Mr. P., aged thirty-two. Anæsthesia produced in three minutes. Extracted three fangs of upper molar. No pain.

M. D., aged twenty-two. Anæsthesia produced in two minutes. Extracted lower wisdom tooth. Patient has slight sensations of pain.

Mrs. P., aged twenty-three. Anæsthesia produced in five minutes. Extracted upper molar tooth—highly sensitive—and lower bicuspid. No pain.

Mr. A., aged twenty-two. Anæsthesia produced in two and a half minutes. Extracted second bicuspid—upper. No pain.

Mrs. P., aged twenty-three. Anæsthesia produced in one and three-quarter minutes. Extracted first bicuspid—lower. Slight twinge of pain.

Mrs. M., aged thirty-two. Anæsthesia produced in two minutes. Extracted lower molar tooth. No pain.

I am, Sir,

Yours obediently,

MAURICE L. DAVIES.

10 Lower Sackville street, Dublin, Nov. 25.

[We think it right to say that our observation of nitrous oxide administration by no means confirms that of our correspondent. The anæsthesia is so transitory as to unfit it for any operation of importance; the appearances of the patient are absolutely frightful, and closely resemble those of the last stage of asphyxia, and the agent is by no means free from the objectionable reflex and after results of chloroform.]

The best that can be said of it is that as yet it has not been publicly stated to have killed any one.—ED. MED. PRESS & CIRC.]

DETERIORATED VACCINE LYMPH.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I received a practical lesson some weeks ago, which I wish to send for the benefit of my junior brethren.

I always insert the vaccine lymph in three spots on each patient, and, transferring it generally from arm to arm, I seldom fail in having true and perfect vesicles. A child was brought to the dispensary having two good and perfect

vesicles, but the third having been on the way coarsely rubbed, exuded from the raw surface a quantity of transparent lymph. Thinking to utilize this, I inserted some of it in the arms of four children. On that day week I found each spot of insertion occupied by a festered surface, but no appearance in any of the twelve spots of true vaccine.

I desired the children to be brought after a fortnight, and having re-vaccinated them in the usual manner they attended last Wednesday at the dispensary, each having good and true vaccine vesicles.

Had I been satisfied with the imperfect vesicles in the first case, not one of these four children would have been properly protected.

Portlaw, Nov. 29.

JAS. MARTIN.

CONSUMPTION IN ICELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Nothing more forcibly illustrates the difficulties attendant on the propagation of new views, assuming my own to be new and true, than that any one could take up with the vulgar prejudice of which Drs. Hjaltelin and Leared have made themselves the mouth-pieces, as to the imagined immunity of Icelanders from tubercular phthisis. What could be more glaringly inconsistent and self-contradictory than the comments of Dr. Hjaltelin? What logician could lend them his assent? In 30,000 cases, he does not say of what, a single tubercle was not to be encountered. Ten per cent. of the deaths in Iceland, avers Dr. Schleisner, are owing to phthisis. No deaths whatever, according to Dr. Hjaltelin, ensue from this cause. Are we to side with Schleisner and common sense, or with Hjaltelin and what really is no sense at all? In 30,000 cases the latter affirms there was not an example of tubercle. Who can lend credence to such a sentiment, unless, indeed, Dr. Hjaltelin's piercing vision could penetrate the bodies of his subjects, or, *mirabile dictu*, he has performed 30,000 autopsies? Such, then, is the halt and insufficient testimony on which Dr. Leared relies for his all too confident assertion, and which he ushers in with a pomp and circumstance that might move a smile but for the very serious issues which are at stake.

The advocates of human interests are none too many. Let Dr. Leared, instead of bolstering up pernicious popular delusions, urge the introduction of sound sanitary views and practices. Let him ask the Danish Government to make Iceland a free port, to remit the taxes on salt, timber, and other necessities, as well as to reconstruct the dwellings of the people in accordance with the dictates of science and humanity. These, with open windows by night—Whympier slept in the open air while in Alaska with the thermometer 50° below zero—would at once set free the Icelanders from tubercle and tubercle-induced maladies. Let him further advise them to get rid of their dogs, cats, and swine, and bury their own daily excreta deep in the soil; so should they get rid of the cysticercous scourge which, coupled with tubercle, now so sadly preys on their poor vitals. Remove the cause, and you remove the effect. Remove cysticerci, and you get rid of the hydatid disease, *hydatidis sygdomer*. Avoid rebreathed, and consequently irrespirable air, and you free the suffering Icelanders not only from *ginkloft trismus nascentium*, but also from the yet worse inflictions of phthisis and scrofula. Consumption is a perfectly artificial and, as I hold, absolutely avoidable malady—~~one~~ only to be put down, as I believe, by the means which for years I have so strenuously and persistently pointed out.

I am, Sir, yours truly,

H. MACCORMAC, M.D.

Belfast, November 29, 1869.

FEMALE PHYSICIANS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—With great regret and astonishment I am informed that a new and rather extraordinary phase is now trying to insinuate itself into our profession—it is nothing more nor less than a phenomenon in these parts of the world; its followers and supporters will, I hope, excuse my want of gallantry when I say that such a revolutionary scheme having for its object the admission of females to the Medical Profession will, if successful, be fraught with the most baneful results to the

profession and the public in general. I am aware that for many years some of the fair sex on the other side of the Atlantic have been permitted to graduate in medicine in that country, but with no very marked use to society; this announcement is not at all very wonderful, the ladies there try to be go-a-headers not alone in physic, but in every other branch of mental and physical labour, even to our peculiar masculine accomplishments *in limine*. I may state, as an opponent to this masculine and unsexing system of female education, I consider myself their champion, but some of our savants north of the Tweed are about endeavouring to introduce a most pernicious innovation, having for its object the propriety of admitting ladies to graduate in medicine, indeed, I expected better from the chivalrous Scot; but I know full well such a project will be scouted from the classic and venerated halls of its time-honoured University.

I candidly admit that ladies might be educated separately for the diploma of accoucheuse, because none of us can question the utility of having scientifically trained female midwifery practitioners, which can only be accomplished by having a distinct school, courses of lectures, and lying-in-hospital attached to same for female students only; beyond this branch I would respectfully ask ladies not to proceed. Females should confine themselves entirely to the practice of midwifery, and, *a la* Nightingale, as trained nurses. There are many objections against ladies studying the profession of medicine and surgery, they are not at all befitting the female mind. All who had studied practical anatomy, dissections, surgery, medicine, and the diseases of the human mind, know right well that a woman is not fit to go through those subjects without seriously destroying the finest qualities of her delicate nature, subjects that require the great strength of intellect, and the stern wisdom of our own sex. As to surgery and anatomy, how on earth could she stand over and dissect dead bodies, or sweep the amputating knife through living limbs? Impossible! Our own feelings are very often taxed to the utmost in such cases, therefore, the study of this profound, philosophical, and very arduous profession, ought not to be undertaken by females. It is tacitly understood by all the members of the profession how repulsive its studies and practice would be to the elegant and refined mind of a highly cultivated woman. We are all aware if ladies attended the medical schools and dissecting rooms how matters would end. She must be a very strong-minded woman indeed, who would venture to dissect and attend medical lectures, &c., amongst a large body of male students; the poor professor would also be in a rather uncomfortable position, when speaking on subjects of a very delicate nature. God forbid I should be such a professor, for I am afraid my teaching would not be a "labour of love."

I cannot understand for the life of me how the softer sex could even think of making themselves doctors. Let me canvass the entire opinion of the enlightened women of these realms, and I venture to say they would at once ignore and repudiate the idea as repugnant to the feelings of their sex, entirely out of their sphere, and prejudicial to those qualities which highly adorn woman. So I hope, then, this move will be futile and ephemeral, that the "women of the period" will recognise the advantage that will accrue to society by their maintaining that status which God has ordained and destined for them, and which the customs of ages has so grandly, and so chivalrously kept sacred. It is not by attending science-congresses, scientific debates, studying this ology, and that ology, or studying for the degree of Medicine Doctor!! Providence has left her plenty of other useful occupations more becoming her sex, subjects pregnant with all the lofty sentiments of refined thought, well adapted for the female student, viz. poetry, music, painting, and the study and culture of languages and literature, &c. All these are most suitable to her form of intellect, as we are aware she has in every age, both in literature and the fine arts, left marvellous works of her genius. Far be it from that I should undervalue the capabilities of the female intellect, I merely state that the peculiarities and nature of the studies of our profession, the mode of acquiring medical and surgical education, the study of anatomy, and attendance with large numbers of our own sex at medical lectures, would pervert the mind of the female student, deprive it of its natural modest tone, to assume only a masculine air, which I may safely assert very few women aspire to.

It was Cato I remember who said before the Senators in a debate on the Appian law, "that if they made women their

equals, they would soon be their superiors." The truthfulness of this statement is rather questionable, and which I cannot at all endorse. From the remotest ages of chivalry up to our own days, woman was always respected by the sterner sex, and respectfully kept in her own proud dignity, fulfilling the important duties of her own sphere without infringing or encroaching on man's domain. Unhappily, things are now taking a different turn. Many ladies are now taking very active parts and dabbling in the affairs of gentlemen. Some are even seeking to be dubbed Doctors.

"Tempora mutantur et nos mutamur cum illos."

If matters go on so in future, paterfamilias must also send the ladies to the university, and, with quadrangular cap and flowing gown, smoke cutty pipes with Jones in the quadrangle, dilate upon rowing-clubs, chaff the old tutor, play chess and smack bitter beer with Tom Browne, soon her terms unconsciously come to close, and she now goes to grind for B.A. But before such an anomalous state of things takes place, I hope our medical authorities will, in rather a gallant spirit, issue a courteous mandate, forbidding ladies from taking medical degrees, because their attainment cannot be consistently carried out, without spoiling and masculating their delicate minds, subverting those exquisite traits and tender feelings that are naturally inherent in the fair sex.

I am, yours very faithfully,

Turloughmore, Co. Galway.

JOSEPH DUGGAN.

THE COLLEGE OF PHYSICIANS OF LONDON.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your very able article of December 8th, on the recent changes made in the College of Physicians, you ask why the College does not confer its Fellowship by a system of examination, after the manner of the College of Surgeons? But I would go a step farther and ask, why are these Members as distinguished from Fellows? Is the division of the English Physicians into two grades necessary? Is it even useful? In what does the distinction consist? There is an examination to test a man's fitness for Membership, but none for Fellowship; the Fellows' election being altogether dependant on chance introduction, or, it may be, favouritism. I do not mean to question the propriety of the selections already made, although I could name a goodly number who could show, at least, equal claims to the distinction, whose names are passed over year after year in the selection of the annual batch of new Fellows which the usage of the College calls up for creation.

In a system of self-election nepotism and its allies must inevitably be in the ascendant. But the days of self-elected bodies are numbered, and the Fellowship of the College is one of the few that remain. The division into Fellows and Members is an example of the old system of distinction without difference, and cannot continue to exist in the present matter-of-fact age. The movement just made by the College can only be accepted as an instalment of justice and right. Let it be completed by the abolition of a useless division, or at all events, let it be a real distinction, and not, as it is now, a doubtful honour.

I am, Sir, your obedient servant,

OH! EXCLAMANTIS.

ON THE CAUSATIVE AGENCY OF THE SKIN AND LIVER IN THE INDUCTION OF PHTHISIS AND OTHER SCROFULOUS MALADIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In reply to Dr. Mulvany's letter in your issue of December the 1st, permit me to say, that I am quite ready to admit that "it is not on the influence of oxygen in its ordinary condition, but of oxygen in its more active allotropic state, ozone, that he relies;" but I am surprised that a scientific scholar as he evidently is, should prescribe the permanganate of potash with sugar as a vehicle for ozone, and maintain that it is not decomposed thereby.

As to the experiment which he adduces in support of this assertion, namely, of "dropping a portion of sugar into a solution of the salt without in the least altering its beautiful colour;" the explanation is simply this, either the portion of sugar was very small, or the solution very strong, and sugar will only decompose a certain quantity.

However, in order to convince Dr. Mulvany of the impropriety of the combination, I will quote a letter from Mr. Condy (and surely he may be regarded as an authority beyond dispute), to the late Sir Joseph Olliffe, an eminent Parisian practitioner, who prescribed for fœtor of the breath, a gargle composed of thirty-six grains of permanganate of potash in eight ounces of water, flavoured with half an ounce of syrup of orange:—

COPY OF MR. CONDY'S LETTER.

"To the Editor of the *Paris Journal of Practical Medicine and Surgery*.

"SIR,—Your number for April last contains an article (6425), giving an account of the efficacy of permanganate of potash for the removal of fœtor of the breath, in the hands of Sir Joseph Olliffe, and setting forth the formula prescribed by that gentleman, in which syr. flor. aurant. is combined with the permanganate. This was a most unfortunate combination in which to prescribe the remedy, since organic substances of all kinds, and particularly saccharine matter, are most destructive of the salts of permanganic acid. I have no hesitation in saying that thirty-six grains of permanganate of potash would be entirely decomposed by ʒiv. of syrup of orange-flowers, and reduced to the inert state of binoxide of manganese. The alkaline permanganates being compatible with very few other substances, are best prescribed extended simply in pure water. In the character of the recognised discoverer of the purifying, deodorising, and disinfecting properties of the alkaline manganates and permanganates, with which my name has publicly been associated in this country, since the year 1856, you will, perhaps, be good enough to allow me space in your valuable journal, to point out the above source of error in prescribing them.

"H. B. CONDY."

Battersea Chemical Works,
May 14, 1863.

LETTER FROM SIR JOSEPH OLLIFFE.

To the Editor of the *Paris Journal of Practical Medicine and Surgery*.

"SIR,—Mr. Condy is perfectly right as to the incompatibility of saccharine and other organic matter with the permanganate of potash; since the publication of the April number of the *Journal of Practical Medicine and Surgery*, I have had occasion to prescribe the permanganate of potash in four cases of fœtor of the mouth, and about a fortnight since, on entering the room of one of the patients, he showed me the bottle containing the mixture, in which I was surprised to find a black precipitate with complete discolouration of the supernatant liquid. Supposing this to proceed from the syrup, I substituted for the latter, a little powdered sugar, when the same discolouration and precipitation occurred. I thenceforth resolved to employ simply the aqueous solution (as in the injection for ozena), containing gr. thirty-six, in ʒvi. of water, or thirty drops in water, of Condy's solution for each dose.

"The deodorising effects were very apparent in the case of the patient above alluded to, notwithstanding the decomposition of the salt; a question may, therefore, arise, as to whether the binoxide of manganese itself may not be considered as an efficient antiseptic? I am quite ready to acknowledge that the Medical Profession ought to feel much indebted to Mr. Condy for the introduction into therapeutics of the permanganates, that of potash especially, than which I believe there exists no more powerful deodorising agent, nor any safer in its mode of administration.

"J. F. OLLIFFE, M.D."

Dr. Mulvany says, "Manganese is a capital tonic, little inferior to iron." I quite agree with him, and have often prescribed the sulphate as a chologogue, if one may be permitted to use the term, nowadays, when it has been so clearly proved that mercurials do not (in healthy animals at least), increase the secretion of bile. Manganese at all events, like mercury, hurries bile through the intestines, thus preventing its resorption and so lightening the work of the lungs and kidneys.

Many preparations are in use in France, but I believe the binoxide is considered inert, to which condition the permanganates are reduced by admixture with oil or sugar.

One would not have expected the result of Dr. Mulvany's observations as to the effect of atmospherical conditions upon phthisical patients—viz., that the patient improves when the air is charged with ozone, since we have been taught to be-

lieve that an excess of ozone produced catarrh or influenza from which we endeavour to shield our poor phthisical sufferers. Schönbein in a letter to Faraday quoted at page 14 of Condy's pamphlet 'Disinfection,' says, "By means of the ozone so produced, I have rapidly oxidized silver at the temperature of 20° C, and by inhaling it produced a capital catarrh."

This consideration probably weighed with Dr. Mulvany when he prescribed doses of the permanganates, rather than ozonize the air to be breathed by his patients, and so allowing it to enter the system by its accustomed channel, and, at the same time, to act directly on the diseased organ.

Facts, however, are valuable, though often fallacious, and Dr. Mulvany deserves credit for his experiments, whether the theory he has built up be true or not, and it is worth knowing that the condition of a phthisical patient improves when the air contains ozone.

I am not sufficiently acquainted with the laws of electricity to suggest another excitant than alcohol, which the doctor prescribes "to supplement the enfeebled nerve power by the generation of thermo-electric currents."

If positive electricity be serviceable, as I cannot doubt after Dr. Mulvany's statement, cannot the atmosphere about the patient, or the patient's body, be positively electrified, following Nature as closely as possible?

As to the benefits derived from residence in elevated localities where there is an increase of ozone, I may remark that the monks of St. Gothard fall victims to phthisis in great numbers. The purity of the atmosphere does not save them.

I am inclined to think the production of tubercle is analogous to that of furuncle, and that, at the time when both are formed, the blood is acid.

The interlobular connective tissue of the lung is, however, very delicate, and when its meshes are clogged with lymph no great pressure is exercised upon it, seeing that it is bounded by empty air-vesicles, so that we don't have actual sloughs, as in subcutaneous furuncle, but an imperfectly vitalized product rapidly degenerating.

To remove and neutralize this hypothetical acidity, I would prescribe emetics, purgatives, and hot-air baths followed by alkaline douches, and I dare say inhalation of oxygen would aid, but I think I have shown that the permanganate in small doses combined with oil or sugar, is useless.

The production of fatty liver in artificial phthisis (result of inoculation) is very singular. It was alluded to by Dr. Charlton Bastian, at a meeting of the British Medical Association.

Can it be shown, is the liver affected before the lungs or after?

Why are the apices of the lungs first affected in phthisical human patients?

Is it so with cats and cows?

I cannot believe with Dr. Mulvany that the bird with its head under its wings breathes a purer air than if its head was uncovered. If I did, I would not reprehend a dispensary patient as I did lately, for sleeping with a blanket thrown over his head; neither the bird's wing nor the blanket, in my mind, serve as a respirator, except by warming the respired air.

The bird's instinct may teach it, certainly, to adopt this method to exclude light and also exclude cold, but I don't think the flexion of its neck is to produce "cerebral venous engorgement," since, though such a condition obtains in coma, the brain contains less blood than usual during natural sleep.

I am, Sir, yours faithfully,

FRANCIS M. LUTHER, M.D. Q. U. I.

Cappoquin, Dec. 7, 1869.

THE DEATH OF MR. JUSTICE HAYES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—We have heard of but one physician that can abolish death, though some men of learning have been bold enough to affirm that scientific investigation discovers no absolute cause why men should die; and I remember a travelling lecturer who undertook to convince credulous hearers that we have really nothing to do but go on living for ever. It must, however, be conceded to the practice of medicine that, within certain bounds, it diminishes deaths, puts it off, at least, and, in short, lengthens the average duration of mortal existence.

As a non-professional reader of your interesting pages, I compliment the country practitioners, and through them the whole faculty, on the promising recovery of the Archbishop of Canterbury, under the almost exclusive care of the two gentle-

men at Broadstairs first called in. Special circumstances would, if named, very probably account for the adverse termination of a somewhat analogous and simultaneous case, that, I mean of the late Mr. Justice Hayes. But, at least, while the Judge has succumbed in town, the Primate survives in the country.

The many instances in which those hardest-worked of working men who work with the head, and wield a heavier manual implement than a Mitchell or a Perry, fall suddenly ill and quickly die, naturally put others, in like circumstances as to employment, upon the anxious inquiry whether you physicians have not some guard or check, some *prophylactic*, as the learned have it, against such alarming and dangerous seizures. You have chairs of medical jurisprudence and forensic medicine, some of which, as I know, are admirably filled; but why have you not chairs of medical strategy? Though the Archbishop seems to be fighting his way through, and though the ex-Bishop of Winchester has not yielded to the first attack, yet we remember that the late Bishop of Lichfield was killed by over-work, and that his energetic successor had scarcely got into the See before he also was knocked up. For the second time within a few years a Judge has been struck down almost upon the very bench. We shall never have another tale from Thackeray, because the strong body in which his strong mind was lodged gave way at its weakest point in the depth of the night. I need scarcely remind you of Bransby Cooper falling dead in the vestibule of the Athenæum.

Take care of yourselves, then; but also kindly tell us how we, who are, perhaps, upon the verge of brain-bursting and of palsy, may understand and answer to the very first intimations of the functions on which we are trespassing, and not go on till they can only convey their faint whispers into dead ears.

I enclose a letter cut out of my morning paper: may I ask you for an opinion upon the points which it starts? What do you think of the old gentleman's remarks on the subject of cupping? Take, for example, myself. "One medical attendant" tells me, for reasons assigned, never to take a purgative without prescription. When, therefore, constipation and brain-work come together, what am I to do? I am but one, our name is legion. To me it seems as if "cupping" were made for these head dangers, being so quick and also so serviceable. What have your more recent men to say to Copland, Wardrop, Cooper, and such authorities? Do you vote the restriction of the *sicca*, as well as the exhibition of a swift cathartic? But when? for the quickest rescue may come too late.

CEREBROSUS.

"TO THE EDITOR OF THE DAILY NEWS.

"SIR,—In reporting the sudden decease of Mr. Justice Hayes you emphatically ask, 'Is there no prophylactic for these sudden seizures? Do they come on without a premonitory sign?' I answer at once and deliberately Yes! to the first, and No! to the second interrogation. Under nature's laws there is no such a thing as sudden death without a warning. Mr. Justice Talfourd had had his warning before the delivery of his charge at Stafford. So had Horace Twiss, who died sitting at a Board of his co-directors: as had also the stalwart and witty author of 'Vanity Fair,' when he woke in the night, was heard to make some bustle in his bedroom, and was found dead in the morning. Nor had the awfully sudden death of Bransby Cooper in the hall of the Athenæum, been without warning. They all had the premonitory warnings, not immediately before their fate, but long before, and more than once, no doubt, which probably were ignored, or not understood—perhaps pooh-poohed by 'our medical attendant.' All the premonitory signs you inquire for are correlative with the state of the venous circulation in the brain, but principally in the *cerebellum*, where stagnation of blood in the larger veins occasions immediate loss of muscular power, impairment of sight and hearing, a great confusion and noise in the ears, generally on one side only, a perpetual dazzle or quivering in the eyesight, followed soon by oppression in breathing, a tumultuous action of the heart, at first to be followed by a great rapidity of its motions, subsiding after, in a few or more hours, into an almost imperceptible action till death supervenes. Such premonitory symptoms indicate immediate danger, but one or two of them may have occurred at irregular (and sometimes regular) periods in the life of the sufferer without exciting anxiety, or were suffered to subside of their own accord, to return again at some future period. It would be interesting to know whether such has been the case with the lamented

had, on the evening of the 21st, taken a smart dose of senna and salts, which had operated powerfully during that night and all next day down to six o'clock p.m. On the afternoon of the 23rd she was suddenly seized with severe pain in the abdomen, a little above the navel, accompanied with retching and vomiting. She seemed in great agony; her pulse small, and 96 per minute. I ordered a pill, containing a grain and a half of opium, every four hours till relieved, and a plaster, composed of extract of opium and mercurial ointment, a drachm to the ounce, to be applied over the belly, and a light poultice over all.

Sept. 24th.—Vomiting continues as severe as before; pain very little relieved; pulse 120, small; great thirst; urine scanty and red; no movement of the bowels since the evening of the 22nd. Ordered ice to be swallowed, the ointment plaster to be renewed on the belly, laudanum enemata, and nourishment to be given in small but frequent quantities.

Sept. 25th.—Symptoms remain as observed yesterday; pulse 125, small; pain very little relieved; vomiting as severe as before; urine scanty. Ordered a calomel and opium pill every four hours, and laudanum enemata.

Sept. 26th.—Symptoms very urgent, indeed; patient seems much worse; tongue and teeth covered with sordes; pulse 130, small; no movement of the bowels; great pain in the abdomen; vomiting of green bile incessant. Ordered the calomel and opium pills to be continued, strong purgative enemata to be administered, and repeated at intervals, and a blister to be applied over the belly.

Sept. 27th.—Patient much in the same state as yesterday; pain very severe; vomiting still the same; nothing was brought away by the enemata. At a consultation today, Dr. Manson recommended a trial of the sulphate of magnesia and magnesia mixture, which was accordingly ordered.

9 p.m.—No improvement; the blister, which had risen well, did not relieve the pain or vomiting. The mixture was vomited every time. No movement of the bowels. To persevere with the purgative enemata, iced champagne, and jelly of beef.

Sept. 28th.—Much in the same state as yesterday.

Sept. 29th.—Still no improvement; seems in a hopeless state; pulse 130, and very small; countenance pinched and anxious; intense thirst; great pain in the belly; no movement of the bowels; vomiting as severe as ever; has kept nothing whatever on the stomach; urine very small in quantity, and red. It now occurred to me to try the effect of the hypodermic injection of morphia in the skin over the stomach, fancying it might produce not only a general sedative effect and relief from pain, but perhaps a local one, also, on the muscles concerned in the act of vomiting, and on the peristaltic action of the intestines. Accordingly, I sent for the syringe and injected fifteen minims of the solution over the stomach, and gave orders that in about three-quarters of an hour after, when probably the full effect of the morphia would be set up, a draught of warm castor-oil and laudanum, an ounce of the one and fifteen drops of the other, should be given, and if vomited to be repeated immediately.

10 p.m.—To my great surprise, I was told that the hypodermic injection had had the desired effect. The pain was relieved in a few minutes, and there was no vomiting; the castor-oil was given at the proper time, and it also had stayed on the stomach, and had operated twice easily. There had been no vomiting since. She feels better in every way, only extremely weak. Pulse 120. To continue the iced champagne, beef-tea, and milk, to observe perfect quiet, and to have a repetition of the morphia injection if either the pain or vomiting should return.

Sept. 30th.—Still improving; the pain has ceased almost entirely, and there has been no vomiting. To inject the morphia at bed-time to-night, as she said she did not last night sleep very well.

Oct. 1st.—Going on well.

From this time she recovered slowly, but steadily. The

morphia after last report was injected twice at bed-time, and then it was omitted, and bromide of potassium given instead. She enjoyed good health up to the present time (May, 1869), never having had any return of the attacks. Now, however, she complains of cough, accompanied with slight hæmoptysis, and on examination tubercular deposit is easily detected at the apices of the lungs.

Now, as in the case first detailed, so in this, nothing could have been more marked than its extreme urgency, and the inefficacy of all the remedies prescribed; and nothing could have been more apparent than the immediate improvement after the injection of the morphia. The two most urgent symptoms, the pain and the vomiting, were almost instantaneously relieved, and the stomach was, as it were, compelled to tolerate the presence of the castor-oil until it passed into the bowels and produced its laxative effect.

IV.—*Obstructed bowels, accompanied with intense pain and vomiting.*

This case, which I shall describe shortly, was pretty much like that just detailed. I was called up at midnight on the 27th April, 1868, to go and see Mrs. B., aged thirty-three, who was said to be dying. I went, and found her in a state of perfect collapse; no pulse could be felt at the wrist; the skin cold and pale. She complained of intense pain, which had come on suddenly, all over the belly, and she had vomited once. Bowels had not been opened for three days. Being six miles from any apothecary, and finding a phial of chlorodyne in the house, I gave her twenty-five drops in a little water, and ordered it to be repeated if vomited immediately, and in two hours if the pain should be unrelieved. I ordered, also, calomel and opium pills, which were to be given, if necessary, when they were procured, one every four hours; an opium plaster to be spread over the belly, and a poultice over it; also, plenty of external warmth.

April 28th.—Has rallied a good deal, but has vomited everything, and complains of the pain being severe, especially so in the hypogastric region. Pulse 115, pretty full; bowels have not been opened; urine scanty and high-coloured; tongue dry and glazed; great thirst; severe headache. I injected fifteen minims of the morphia solution over the part where the pain was complained of, and ordered a black draught to be given an hour after.

April 29th.—The pain, which was immediately relieved on the injecting of the morphia, has not returned, and there has been no vomiting since the draught operated twice, bringing away copious offensive dejecta. Feels much better. Pulse has fallen to 72. Ordered the morphia to be injected again if the pain or vomiting should return.

May 1st.—Has not required the morphia; feels pretty well, but weaker, and has no appetite. Has not slept well during the last two nights, and still complains of some headache. Ordered bromide of potassium and tincture of hops before dinner and at bed-time.

May 10th.—Feels now quite well.

This case also showed symptoms of great severity, which were very speedily relieved by the hypodermic injection. During the past six years I have employed this method many hundred times, and almost always with the best results. The above cases show how valuable it is in angina pectoris, and in obstruction of the bowels, accompanied with severe abdominal pain and vomiting. And every day experience shows how good results can be obtained from its employment in rheumatism, both acute and chronic, lumbago, sciatica, insomnia, mania, melancholia, neuralgia, delirium tremens, threatened abortion, in various departments of midwifery, &c. The only remedies I have used hypodermically have been morphia, atropia, and caffeine. Atropia is a powerful and effective remedy in many cases, but not so safe nor so pleasant as morphia, which possesses nearly all the advantages of the other. I tried caffeine in one or two cases, but was disappointed in it. In one patient, suffering from insomnia, it produced in-

tense sickness, and had no effect in relieving the sleeplessness. In another I gave it where much pain was complained of, without affording any marked relief. The dose I gave in both cases was one grain, as recommended by Dr. Anstie, in a paper published by him in the *Practitioner* for July, 1868.

REPORT OF A CASE OF "INTUSSUSCEPTION."

Read at the Meeting of the Medical Society of the College of Physicians.
By S. M. MacSWINEY, M.D.

It is well known to the practical physician that diseases of the organs contained in the abdominal cavity are frequently marked by an obscurity which renders their diagnosis difficult at all times, and sometimes not possible. So much so is this the case, that many physicians hold the opinion that—contrary to what at first would appear likely—it is easier to arrive at a correct knowledge of the actual morbid state of an organ contained within the cranium or the thorax than of one located in the abdomen. I need only recal to the recollection of members some of the affections met with in this region to render the justice of this opinion apparent. Amongst the solid swellings which may present themselves, *cancer* and other malignant growths, fibrous tumours, and the several varieties of mild hypertrophy, and those cases—often too full of difficulty—where impacted faeces constitute the enlargement, may be cited as notoriously surrounded with much obscurity in regard of their diagnostic discrimination. Abdominal aneurisms, hydatids, ovarian and other dropsies, are good examples of fluid-containing tumours whose diagnosis is frequently impossible, or, at least, perplexing. I will only glance at the insuperable difficulty of arriving at a positive diagnosis between disease and pregnancy in those cases presented to the physician where the latter may be only in the early stage.

The differential diagnosis of the acute inflammations of the different tissues and organs contained within the abdomen is also—not seldom—difficult to make, and of all those dangerous states, accompanied with peritonitis, and tending to a rapidly fatal conclusion, which we meet with in practice, there is, perhaps, no one so obscure as the affection known as *intussusception*. The following case affords an instance in proof of this statement:—

A man, aged thirty-two years, presented himself at midnight, September 24th, 1869, at Jervis-street Hospital, urgently seeking to be admitted. He complained of suffering from an attack of most severe abdominal pain. He was at once received by the "Resident," and I visited him at an early hour on the following morning, when he gave me the following:—

History.—He was a van-driver by occupation. He was of temperate habits, and had enjoyed moderate good health all his life. About three weeks ago he had an attack of diarrhoea, accompanied with a good deal of pain in the bowels. He was a patient of Dr. Mapother at this time, in St. Vincent's Hospital, where he remained for a fortnight. He then left, feeling nearly quite well, but still suffering some abdominal pain. He remained better for four or five days, when an aggravation of his intestinal distress occurred, and reached to such a degree of severity that he was compelled to seek admission, as described, into Jervis-street Hospital.

Present state.—He has a worn, haggard, and anxious expression of countenance. His decubitus is on the back, with the legs extended. He has a basin beside him, into which he occasionally vomits a thin, brownish-coloured fluid, scanty in quantity, without odour, and having, he says, a bitter taste. His tongue is dry, and covered with a greenish-brown encrustation. His pulse is 100; small—compressible. In reply to inquiries, he says that nothing will remain on his stomach, that he suffers from thirst, but above all that he has great pain in the belly. He describes this pain as "coming and going;" when it is absent he is, comparatively, at ease; when a paroxysm occurs he grinds his teeth and writhes in agony. He says that in the commencement of this attack *he passed pure*

blood, that his bowels are now *costive*, but not *confined*, as he occasionally passes an evacuation, and that he does not make much water. Upon proceeding to examine the seat of pain the following may be stated to be the condition in which I found it. There was nothing remarkable—neither increase nor diminution in size—in the appearance of the abdomen when pain was absent, but on the approach of a paroxysm a series of *waves* might be seen to pass over its surface, the intestines, in their peristaltic movement, rising into prominence at one point, then subsiding there, and proceeding, in a vermicular manner, in a succession of undulations over the entire abdominal area.

Digital percussion demonstrated the presence of some—not much—*tympanitis*, and palpitation, carefully applied and carried out, failed to detect any solid tumour in any part of the affected region. It is deserving of notice that the examination of the abdomen, made by pressure of the fingers, was of negative effect so far as pain was concerned; it neither relieved nor aggravated the suffering.

It is not necessary that I should fatigue members by a dry recital of the daily progress of this case, which presented no circumstances needing special record. In like manner I pass over all detail of "treatment;" the case was regarded as hopeless from the commencement, and I had but one principal object in prescribing for him, namely, to relieve his sufferings and produce some sleep. During the entire course of his illness he had some vomiting daily, which was never stercoraceous; and the bowels occasionally acted spontaneously.

He daily wasted and grew weaker and weaker: towards the close of his life he was almost free from pain. He died, October 18, a little more than three weeks after he came under my care, and about six weeks after he first complained of diarrhoea.

Twenty hours after death I made the autopsy; and, confining myself to what I observed in the abdominal cavity, the following was the condition presented. There were slight adhesions, easily separated, between several contiguous portions of the contents of the abdomen. These adhesions were due to lymph exudation, which, of a whitish colour, was present in small quantity. There was air, but not in very considerable quantity, contained in some portions of the small intestines.

Two solid masses were to be felt, one in the epigastric region, and running to the right side; the other in the right iliac locality. These tumours were bound down and attached by lymph adhesions to the neighbouring intestines. Upon carefully examining these tumours it was found that they were due in each instance to *intestinal intussusception*. Looked at externally, the first started from about the commencement of the *jejunum*, and consisted of a large extent of ileum involved and adherent, and the origin of the second swelling would appear to be at the middle portion of the ileum, from which point it extended to the *caput coli* including all the intervening small intestines in a dense mass matted together. Inasmuch, however, as the process of *intussusception* is one which takes place from *above downwards*, a portion of intestine becoming contracted, and dropping into the more expanded part beneath it, the point in those two instances respectively where the strangulation seems to commence, is in reality the point at which the process of involution was arrested.

In the case which I have just related, the diagnosis was not made during life. That there was partial intestinal obstruction was but too apparent, but I failed to detect the precise obstructing agent. The difficulties I had to contend against in arriving at a correct diagnosis may, perhaps, be indicated under the following heads:—

1. *The character of the vomiting.*—During the entire progress of this case the matter ejected from the stomach was at no time considerable in quantity, and was never faeculent. In complete occlusion of the intestine, from any cause, accompanied by vomiting, and continuing for any time, the ejected matter contains some portion of faeces. But,—

2. *There never was complete occlusion of the bowels.*— Sometimes the bowels were very much confined, and then enemas brought away masses of hardened fæces in large quantity, and at other times there was a form of diarrhoea present, and small, loose, alvine discharges would be frequently passed.

3. *The intestinal distension with air was never considerable.*—But usually, in those cases there is great, sometimes enormous tympanitis from this condition of intestine. Finally—

4. *This affection occurs with comparative rarity in the adult.*—As is well known, children suffer from attacks of intussusception much more frequently than grown up people.

With these remarks I draw the report of this case to a conclusion.

REMARKS UPON THE CONTAGIOUS DISEASES ACT.

By THOMAS WORTH, M.R.C.S., Nottingham.

In the office of a newspaper editor the other day, my attention was called to an article on the above subject in the *Pall Mall Gazette* of the 19th ult., which, from beginning to end, was so full of mis-statements and inaccuracies that, for public reasons, I shall be glad if you will allow me space for a few observations on the subject. Experience teaches me that the journal referred to will not be candid enough to publish a letter which exposes its blunders, nor just enough towards the public to admit anything about the Contagious Diseases Act, except from those who favour that measure, or—judging by the article in question—from those who do not mind distorting facts to suit their own particular crotchets. I regard this subject as of such unspeakable importance that I am anxious in some measure to undo the mischief done by the spreading of erroneous doctrines by the *Pall Mall Gazette* and other journals, the editors of which most unfairly exclude from their columns anything adverse to this abominable law, whilst they are eager enough to give entire columns in its favour. This partiality is, to my mind, not only unwise, but unjust to the people.

The *Pall Mall Gazette* states that under the operation of the Contagious Diseases Act venereal disease has been reduced at certain military stations. This is not true. At every one, as you will see by the accompanying table, the disease has increased.

Stations where the Act is in full force.	Average per cent. of soldiers affected with venereal disease from Oct. 1866 to March 1868.	Average per cent. of soldiers affected with venereal disease from April 1868 to March 1869
Chatham	22.58	24.00
Sheerness	12.34	13.57
Portsmouth	20.65	24.67
Devonport	10.54	15.67
Woolwich	17.99	18.45
Aldershot	18.77	20.35
General average ...	17.52	19.59

At one station, specially omitted from the table, you will see it has nearly doubled. Thus, at Shorncliffe, the percentage of syphilis was 42 in 1867, but was increased to 79 in 1868, although the Act had been most stringently enforced. Again, the only disease that it is desirable for the public benefit to reduce is the constitutional disease, the only contagious disease of venereal origin of importance. On this point Dr. Balfour, the head of the statistical branch of the Medical Board, says, in his evidence before the Commons Committee, "I am quite prepared

to say that it is not successful in reducing the amount of secondary disease, which is the great thing that we have to endeavour to reduce!" Mr. Simon also observes in his report to the Privy Council, that "he has vainly looked for evidence to show that the amount of true syphilis has been diminished by the Act." In fact, the evidence altogether is *dead against* the beneficial character of the iniquitous measure.

The *Pall Mall Gazette* says, that "the health of the Army is decidedly improved." This is also false, as you will find on referring to the last annual report issued by the Medical Department of the Army, in which it is stated that venereal diseases are not only unabating but *increasing* in the Army; the *increase* having been 33 per 1,000 of the force. Remarks at the close of the Report, commenting on this increase, say,—“It is surely time that the *inefficiency* of the Contagious Diseases Act should be recognized.” Further, the *Pall Mall Gazette's* quotation from Mr. Swain's pamphlet, as to the reduction of disease among the men at Devonport, is not correct. He states that 44 per cent. of contagious diseases (not true syphilis only, but all four lumped together) existed among the men in the Royal Navy prior to the Act of 1864, and that in the return ending March 31, 1866, the percentage was reduced to 19.529. Now, the Act of 1866, which unhesitatingly introduces the Continental system, did not come into force until *after* the period up to which those statistics were compiled, so that the reduction of disease was effected under a law which existed when the hospitals were crowded with *voluntary patients*, and when only *known* prostitutes *known* to be diseased were interfered with. In fact, interference was necessary. The statement, however, as to the reduction is not borne out by the Parliamentary statistical tables, and the Admiralty are specially dissatisfied with Devonport. The *Lancet* observes that they have it on the best authority, that disease is on the *increase* there, and the civil surgeons *have consequently been removed from their charge of the Lock Hospital beds.*

In estimating the number of diseased persons applying to the London Hospitals for relief, the *Pall Mall Gazette* commits another error by counting the *same person*, in many instances, as often as *fifty-two times over!* Thus, if one patient was ill for a year, he would figure as fifty-two persons suffering from disease. To form a correct conclusion, the *increment* only should be multiplied by 52. For instance, out of 300 or 400 patients, probably 20 would be discharged weekly, and be replaced by about the same number of fresh patients. Instead, therefore, of multiplying 370 by 52, 20 should be multiplied by 52, which, as you will doubtless perceive, gives about 1,000 instead of 19,240 which is the total stated in the romantic calculations of the *Pall Mall Gazette.*

Further, that journal observes that the Committee of the House of Commons approved of this measure. But the *Pall Mall Gazette* declines to tell the public that some of the members of that Committee were active and energetic members of the Association for extending this Act to the civil population; that others were previously strongly disposed to favour legislation of this kind; that, with but one exception, all the witnesses examined were in favour of the Act, and most of them pecuniarily interested in its continuance; that for some reason or other best known to the promoters of the Act, not a single medical man of eminence and experience known to be opposed to the measure was examined, with the exception of Mr. Simon, and that even he was told by Dr. Brewer, the Chairman of the Committee, that his opinion, "whether it would be advisable or not advisable, or possible or not possible to extend this Act," was not required. In fact, Mr. Simon, on his second examination, was deliberately snubbed. Now, Sir, before that Committee the Contagious Diseases Act *was on its trial*, and a more unfair and unsatisfactory trial of a matter so serious was never heard of. With evidence on that side only, and with professional and other evidence against the Act de-

liberately excluded, it is impossible that the country can respect or rely satisfactorily on any decision expressed by that Committee.

Finally, the *Pall Mall Gazette* expresses an opinion that evidence from foreign countries is necessary. Permit me then to add that if this evidence is fairly collected by *disinterested persons* the Contagious Diseases Act, as a compulsory measure, would be wiped off the Statute book. The people of England would not accept nor pay for the working of a law which foreign experience proves to be a farce. Allow me to quote from Dr. C. R. Drysdale, who, after a very recent medical trip to Paris, writes as follows:—

“I am much interested in seeing that plague of modern days (syphilis) abated in its ravages, and were this plan of our *confrères* likely to accomplish this end, I would support it; but, is it likely to do so? Let us see: I told you that I had visited frequently the two hospitals in Paris, Lourcine and the Midi, each of which was full, and each of which contained 300 beds, and that 100 out-patients daily came to the Midi for advice. But I found at the Hospital St. Louis that an immense proportion *both of the in and out patients were venereal cases*; at the other hospitals also I found the same thing. So that I asked myself, is it true that the Parisian system, so much talked about, has really the effect in large towns of lessening the spread of venereal contagion? and, Sir, I had no hesitation in replying in the negative to this question. Well, then, if it does not lessen venereal contagion, has it no evils of itself? It has. The women of the Dispensaire may be compared to *white slaves*. They have no liberty; but are as completely under the espionage of the police as a galley slave is. The Habeas Corpus Act, of which we justly boast, can have no meaning for these women. They can be shut up in a gloomy prison, St. Lazare (which I have visited in company with my friend Mr. Dunn), at any moment for any length of time the physician pleases. I would not like to be that physician. If you call that *equality of rights*, what is inequality?”

In conclusion, permit me to say that the sense of justice and right, which should in all cases reign paramount in an editor's mind, must in the case of the Editor of the *Pall Mall Gazette* be considerably warped, else he surely would not lend his advocacy to a measure which degrades women, debauches men, destroys the liberty of the subject, and, as I can prove, *increases disease*, without considering the subject most carefully from every point of view, and when proved to be in error *candidly saying so*, that the public may not be deceived.

Hospital Reports.

ROYAL FREE HOSPITAL.

On a visit to this Hospital lately, we witnessed the extraction of a fibro-plastic tumour from the neck by Mr. John Hill. The patient was a man of the age of thirty, and the tumour, which was, when excised, found to be of the size of a very large walnut, was fortunately free from connection with any of the numerous vessels of the region. The nature of the tumour was similar to that described as fibro-plastic by Lebert. It was hard, and when cut reminded one in a great degree of the appearance of scirrhus, except that it was not quite so dense, and that it did not cry under the knife.

Mr. Hill has now under his care a young woman, sent by Dr. C. Drysdale, who presents on the right side of the scalp a pulsating tumour, connected with the temporal artery, and also with the occipital artery, and probably with the internal carotid artery, by means of the supra-orbital branch of the ophthalmic. This case presents many difficulties, and Mr. Hill was not decided as to what operation would be most likely to prove adequate to its cure. In the first place, there was considerable dilatation

of the temporal artery, and this pointed to the possible disease of several of the vessels, rendering the tying of some of them likely to be followed only by temporary benefit to the patient's tumour. Possibly the only operation likely to effect the cure of the case would be, he remarked, the ligature of the common carotid artery, just at the point of bifurcation of the internal and external carotids; but the danger of this operation made him pause to consider the matter more leisurely, and possibly to make trial first of the ligature of the smaller supplying arteries before having recourse to the more important trunks.

Mr. Hill has under his care at the present time a case of stricture which he has successfully treated by Holt's plan of forcible dilatation. The patient, a man, aged 56, has suffered from stricture for ten years, after a gonorrhœa contracted some years before, which had not quite left him. When he entered on December 12th, he complained of acute pain in right lumbar region, and frequent and urgent desire to pass water. This was not, however, caused by retention, as but little urine was in the bladder. A very tight stricture was ascertained to exist, and catheter No. 2 was passed with some difficulty into the bladder, drawing off a small quantity of urine. This urine was albuminous. Patient had a powder, gr. x. of pulv. Doveri at night, and was cupped to four ounces in the loins. The pain disappeared after this, and the urine lost the albumen. On the 15th, Mr. Hill passed Holt's dilator, and at once split up the stricture to admit of No. 10 being passed. The pain was sharp, but merely momentary. The stricture was situated just in front of the triangular ligament. No blood was lost by the operation. Patient is now perfectly well, Dec. 16th, and No. 10 can be passed with perfect ease into the bladder.

UNIVERSITY COLLEGE HOSPITAL.

LAST week, in the out-patient department, we saw the following cases under the care of Dr. Ringer:—

CASE 1.—A man, with attack of catarrh and rheumatism. Dr. Ringer ascertained the temperature under the tongue. This being 102, he prescribed the tincture of aconite in doses of one drop every hour. Dr. Ringer informs us that this remedy lessens very soon the abnormal heat of the patient in cases of acute bronchitis and other states accompanied by præternatural heat.

CASE 2.—A woman, aged 40, suffering from pyrosis of an acid fluid, was treated by means of tincture of nuxvomica. Dr. Ringer is much in favour of the use of sulphurous acid in the treatment of pyrosis; but thinks it most effectual in cases where the fluid brought up is neutral in taste.

CASE 3.—A child with catarrh was treated with tartar emetic wine. Dr. Ringer is much in favour of antimony in the treatment of bronchitis in children where much spasm is present.

CASE 4.—A man, aged 35, with severe frontal headache, the result of over application to desk work, was treated by the application of Dr. Richardson's freezing process to the skin of the forehead. This was used until the parts were quite frozen.

We remarked that Dr. Ringer pursues an admirable plan of always prescribing in hospital practice but one remedy at a time. Of course, it is only in this way that therapeutics can ever be expected to make any great advances.

CASE 5.—A child with ascarides was treated with gr. iv. of santonine in the morning. Dr. Ringer thinks very well indeed of this remedy in ascarides.

METROPOLITAN FREE HOSPITAL.

(Under the care of Dr. CHARLES R. DRYSDALE.)

Dr. C. DRYSDALE has lately had four cases under his care of absence of spermatozoa, accompanied by sterility, and in all probability the cause of the sterility.

CASE 1.—A gentleman, of great scientific acquirements, contracted gonorrhœa, September, 1865. In December, 1865, he had orchitis in left testicle. In March, 1866, orchitis of right testis. Both of the epididymes were indurated, and remained so after the gonorrhœa ceased. This gentleman, an excellent microscopist, examined his seminal fluid frequently since that period, and found it invariably without spermatozooids. Married February, 1867, to a lady with two children; she has since then remained unimpregnated, and the gentleman reports that spermatozooids are still absent from his semen.

CASE 2.—John D., 44, seen 1st February, 1867. Had been married 16 years to a second wife, after having been formerly married to another woman, by whom he had one child. His second wife was 33 when he married her. He has not had children by her. Both epididymes indurated. He had 16 years ago, before marriage with his second wife, gonorrhœa and double orchitis. 4th February seminal fluid examined. No spermatozooids seen. Sexual appetite not impaired.

CASE 3.—John M., 25, came to the Metropolitan Free Hospital, April 3, 1867, complaining of impotence. Had been a great masturbator, from age of 13 to 21, twice or thrice a day. Married at 22; has not had children. Strongly built, and no appearance of delicate health, 11 stone 2 lbs. in weight. Complains of rapid ejaculation in coition, and subsequent depression, pulse 75. Diarrhœa when excited. Slight tingling is felt in perineum when micturating. "Dreadfully nervous, cannot go along streets without thinking he is beheld by everyone; agitated and exhausted at mere trifles." Is a draper's assistant, and "this has been the cause of his dismissal, through being so agitated and nervous, sometimes obliging him to leave the customers to be served by some one else." May 10, sent his wife to the Farringdon Dispensary, who says he is almost out of his mind at times, and is very desponding. The seminal fluid of this patient was examined several times, and no spermatozooids were discovered. Had not had gonorrhœa; but the epididymes felt hard. Dr. C. Drysdale remarked on the ignorance of such topics, common to himself, with many of the members of the Profession in this country. He was persuaded that many interesting and useful ends might be attained if such cases as the above were studied and frequently discussed in medical societies. Such cases were better understood in Paris.

CASE 4.—A medical student contracted syphilis in 1867. A year afterwards he had syphilitic sarcocele of both testes, which rapidly disappeared under gr. xx. doses of iodide of potassium. At present, December, 1869, no trace of spermatozooids is seen in his seminal fluid.

Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

DECEMBER 13, 1869.

P. MARSHALL, Esq., President.

Mr. R. DUNN related a case of poisoning by aconite, death appearing imminent; but by the vigorous administration of sal volatile, brandy, and chloric ether, besides strong coffee and beef-tea, a successful termination was effected.

Dr. GREENHAUGH mentioned the case of a patient who had come under his care for supposed prolapsus uteri, but which, on examination, proved to be a thickened urethra surrounded by a spongy growth, the nature of which growth had not yet been ascertained.

Mr. DE MERIC mentioned a case of retention of urine in a patient suffering from stricture, in which puncture of the bladder through the rectum had been resorted to with the best results. He wished to have the opinion of Messrs. Lee and Bryant upon the case.

Mr. LEE considered the case one of perineal section, which

he considered an easier and more natural operation than puncture of the bladder through the rectum. He mentioned that a fistulous opening through the rectum was more serious than through the urethra.

Mr. BRYANT, on the other hand, approved of Mr. de MERIC's operation, considering the perineal section more difficult, and he never had any fistulous openings follow his operations.

Mr. BRYANT then read the paper of the evening on the treatment of disease of the knee-joint, more particularly in reference to operative interference. He began by stating as a rule, no operative interference was necessary in inflammatory disease of knee-joint without disorganization. When suppuration has taken place of diseased synovial tissue a cure by natural processes assisted by art is generally to be secured. When the disease begins in the bone, operative measures are demanded. A cure by ankylosis is by no means uncommon in the former case. During the acute stage, danger to life is great; the question arises, then, whether to amputate or no in order to save life; as a rule, amputation or excision for acute suppurative disease generally is fatal. Mr. Bryant preferred making free incisions into the joint, and washing out with warm water, he considers this ought to precede other operations. Mr. Bryant then read three cases of diseased bone in the knee-joint, resulting from articular osteitis, in which he had removed the sequestra; and the patient recovered with ankylosed joints, and one similar case in which amputation had to be performed. In disorganized joint, the question is, amputation or excision. In amputation of thigh for chronic disease of the knee-joint, taking patients of all ages from his own tables, Mr. Bryant found 188, from Dr. Cormack's 137, total, 325; of these 66 died, 259 recovered, mortality being 20 per cent., or 1 in 5. In Dr. Hodges' work Mr. Bryant found 178 cases of excision of the knee for chronic disease, 70 died, and 100 recovered, mortality 39 per cent., or 1 in 2½. Mr. Swain has given the following up to 1865: 316 cases of excision had been performed, 85 died, or 27·2 per cent., 9 of these having died after amputation, which had been deemed necessary in 39 cases. Since 1865, 74 cases are given, 25 of which died, or 33·7 per cent.; 4 also died out of 11 that underwent amputation; 29 out of 74 dying, or 39 per cent. Mr. Swain gives also a select list of 82, 15 died, 4 others recovered after amputation. We thus have 472 cases of excision of knee-joint, and 129 deaths, or 27·3 per cent., 13 of these being after amputation. If, however, the results of both operations are considered at different periods of life (a point of immense importance), the following striking results come out: In amputations for chronic disease of knee-joint in patients under 20 years of age, out of 69 cases 3 only died, being 4·3 per cent., or 1 in 23. In excisions for similar cases and same age, out of 97 cases 27 died, or 27·8 per cent., or 1 in 3·2·3. In amputations between 21 and 40, out of 119 cases, 3·38 died, or 32 per cent., or 1 in 3. In excisions, out of 74 cases, 39 died, or 52·7 per cent., or more than 1 in 2, the difference being 20 per cent. against excision. Admitting excision to be a good operation, do the advantages justify the extra risk? Mr. Bryant thought not, he also considered an early operation the most successful, it should not be performed when an operation is demanded to save life, only when local disease is steadily progressing in spite of treatment. In conclusion, Mr. Bryant hoped the advocates of excision would recognize the results of experience, and not shut their eyes to those cases that tell against the operation, the point to be settled being the period of the disease in which excision should be undertaken as an operation of expediency. Mr. Bryant is inclined to think that excision may not only be a justifiable, but successful operation.

An interesting discussion then took place, in which Mr. W. Adams, Mr. Henry Lee, and Mr. de MERIC took part.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

DR. DRUITT in the chair.

A PAPER was read by Mr. Acton, in the rooms of the above Society, on Saturday, Dec. 18th, as to the feasibility of extending the provisions of the Contagious Diseases Act, 1866, to London. Mr. Acton observed that the way in which the Act of 1866 had been carried out, and the manifold advantages which had been obtained by its means for the soldiers and sailors of this country, added to the fact that the Act had caused the women who carried on

prostitution to be more cleanly in their persons, and more decent in their conduct and language, made him greatly in favour of extending the provisions of the Act to the civil population; and he particularly desired to hear from the gentlemen present what their opinion was as to the possibility of extending the provisions of the Act to the population of London. Mr. Acton showed by statistics that since the application of the Act to the soldiers and navy, there had been a great decrease in the amount of contagious disease in the services, and especially in the amount of disease of true syphilitic character. Gonorrhœa had not so much been lessened; but the more important diseases had been considerably lessened in frequency. In concluding his paper, Mr. Acton referred to a pamphlet by Dr. C. E. Taylor, of Nottingham, as being a violent party pamphlet, and asserted that many of the statements therein contained were exaggerations; for example, it had been stated in that pamphlet, that Dr. C. Drysdale had said, that speculum examinations sometimes carried the contagion of syphilis. This he (Mr. Acton) denied. With respect to Mr. Simon's arguments, also, he thought that they were all based on assumptions, and that all experience on the Continent showed the benefit of extending the provisions of the Act to the civil population.

Dr. Charles Drysdale said he did not mean to say that soldiers, who were an enslaved class, and not permitted to marry at the very age at which they ought to have partners of the other sex, ought not to be kept from disease if possible; but as to applying the Contagious Diseases Act to London, he thought it was an absurd and ill-considered idea. In Paris, even, a city where the Act was first enforced, and where it was now carried out with the greatest care, the amount of syphilis was, he was persuaded from repeated observation, greater than in London, in proportion to the size of the city. He had asserted this to be the case in 1867, before the International Congress, when M. Ricord presided, and M. Lefort had said that he believed the assertion to be true. If this were granted, the cause was gained, since, unless the advantages were immense, no one would like to have in London police spies and a prison like St. Lazare, to put the poor "white slaves" of prostitution into, and keep them in for months. Prostitutes were surely not felons, and, at any rate, it was a disgrace to all justice to make women prisoners in a gloomy prison, and to let men go about free and infect them with impunity. The *mouchards* or spies of Paris obtain three francs for every sick girl they conveyed to prison, and hence they often did most disgraceful things. Syphilis had been often spread by pipes, by kisses, by cups, by catheters, and by the mouths of bottles in glass blowing, and although this was a minor point, it was rather too much for Mr. Acton or any one to assert, that it was at all unlikely that it was occasionally spread by the speculum examinations, he (Dr. Drysdale) had seen used at Paris police office and elsewhere. His remedy for prostitution was, like that of Mr. Simon, early marriage, to which he would add, few children (two or three only to a marriage) and *facility of divorce*, since poverty and unhappy marriages were clearly the chief factors of prostitution. The Act in London would embrace 40,000 or 50,000 women, if carried out as Lefort wished it to be carried out in Paris. It would, he hoped, in London, be replaced by large municipal free venereal hospitals, with a total of 800 beds, perhaps. This would do all that any Police Act could do, without its evils.

Dr. Stuart said there had not occurred, as far as he knew, any case of contagion from his speculum practice among the prostitutes. The instruments were carefully cleaned, dipped in hot water, and rubbed, after each examination. There were 220 prostitutes in Woolwich, and their manners were now much better than they used to be; and he had only known of one case, where the police had brought up a woman who was not really a prostitute. The girls seemed very friendly with the inspectors, and were quite obedient now, although at first they had been turbulent and unruly.

Dr. Liddle was now in favour of extending the provisions of the Act to the civil population, and thought it might be carried out well enough in London. There were 442 deaths from syphilis per annum, and the amount of disease was most extensively spread.

Dr. Aldis was in favour of extending the Act to the civil population and to London. He had found that the women who went into the refuges very frequently returned to prostitution; some of them, however, took situations or mar-

ried. As to Paris, Dr. Montfaucon many years ago had stated that there was a diminution of disease by means of the Act of Parent Duchatelet.

Dr. Ballard said that the magnitude of London population made him despair of carrying out the provisions of the Act in that city. Women in one district, if tormented or diseased, would go off to another district, unless registered and with tickets. And this conduct of theirs would cause prosecutions, and make the Act not to be worked quietly, which was much against the extension of it to London.

Dr. Webster had found that in Naples and Moscow, where prostitutes were registered, the number of beds required for treating them was very large, and he had always understood from the medical men in these places that there was more disease than in this country, since this plan tended to increase the extent of prostitution. And it was absurd to punish women and let men who infected them go free.

Mr. Kettle, of Scotland Yard, said he thought there were about 6,000 prostitutes whose names and addresses were known to the police, but, perhaps 60,000 who were known to be prostitutes, in London. This was only a good guess. Most of the women frequented particular beats, and were known to the police of that beat. It would not be easy, he said (in reply to a question put by Mr. B. Hill) to look after a prostitute who went from one district to another unless they had cards, and were registered.

Dr. Letheby was in favour of the extension of the Act to the civil population. He quoted the statistics of the amount of venereal contagion at our large hospitals, and spoke of the number of illegitimate births in the country. He thought it, therefore, advisable to extend the provisions of the Act to London.

The debate was then adjourned.

The date of adjourned meeting is not yet fixed.

Literature.

PROSTITUTION.*

It gives us very sincere pleasure to welcome a second edition of Mr. Acton's well-known and most instructive and interesting work upon prostitution. The population of this country owe a deep debt of gratitude to that gentleman, for the bold way in which he has for many years exposed the terrible evils arising from this unhappy social condition, which, indeed, seems to be more widely spread and more injurious to human happiness in our day than at any former period in human history. The first edition of the work was published twelve years ago. By the way, we may remark in passing, that it is a fact disgraceful to the intelligence of our London faculty of medicine, that Mr. Acton was not a long time ago elected to the post of Medical Adviser to the Lock Hospital. His publications on this subject, have proclaimed him as the British Ricord; and we deeply regret that inferior men should have wasted the opportunities for observation which Mr. Acton alone among us would have been able to utilise.

Mr. Acton has always been inclined towards the introduction of the French system into this country, and now seems to be more than ever convinced of the absolute necessity of doing so, or of extending the provisions of the Contagious Diseases Act of 1866 to the civil population. According to his views, the working of the Act has been attended with the happiest results, both as regards the health of the army and navy, and the sanitary and moral improvement wrought in the unhappy women coming within its scope. Mr. Acton must prove this before we agree with him. Mr. Acton says he is as fond of liberty and has as much regard for religion as any man; but he considers the extension to venereal diseases of the principles used in other preventable diseases, no infringement on liberty; and, furthermore, religion "is on his side." The last argument we should like to get rid of at once. If by religion he means the clergy, he is wrong,—not that this should daunt any scientific man, for clergymen are as frequently wrong as right in such matters; if by religion he refers to morality, he must prove, of course, as he tries to

* Prostitution, considered in its moral, social, and sanitary aspects in London and other large cities and garrison towns. By William Acton, M.R.C.S., &c. London: J. Churchill. Second edition, 1870 pp. 303.

do afterwards, that the Contagious Diseases Act will tend to increase the highest happiness of the race. We quite agree with the remark in the preface, that the voluntary system has been tried long enough, but, then, the voluntary system's chief fault has been in this, that subscribers to hospitals have been too superstitious to admit of taking in poor diseased girls into their charities. The remedy for which would evidently be the erection of municipal hospitals under poor-law regulation for venereal cases, similar to the *Lourecine* of Paris. Let us have no St. Lazare, Mr. Acton, if you please. His examination of the character of prostitution points to prevention, amelioration, and regulation of the evil. Under the head of prevention, he speaks of the overcrowding of families (large families!) and making better provision for the relief and suitable employment of women. He proposes to make seducers substantially responsible for the support of bastards—to procure facilities for affiliation, and to assist pregnant women during confinements. These measures, added to the just employment of the Foundling Hospital funds, would, he thinks, greatly lessen prostitution, illegitimacy, and infanticide. A Government Board is proposed to look after the working of the bastardy laws and the Contagious Diseases Act, and the care of fallen women. It seems to him vain “to shut our eyes to the fact that prostitution must always exist.” Well, we don't agree with this. But of this more hereafter. Mr. Acton thinks that the State has a right to insist that any woman in selling her favours shall not become a means of communicating disease, just as it looks after the sale of poisons, bad meat, and fish. He is peculiarly interested in the regulation of prostitutes, because the great majority of these women, sooner or later, enter society again. It is only by means of the machinery of the Contagious Diseases Act extended to the civil population that we can discover and detain till cured the women affected with syphilitic disease. There are ten chapters in this work. The first defines prostitution, the second speaks of English prostitutes, the third of diseases arising from prostitution, the fourth speaks of the existing control of prostitutes, the fifth of prostitution abroad. Then comes in chap. vi., the causes; in chap. vii., the Contagious Diseases Act; in chap. viii., the recognition of prostitution in civil life; chap. ix., treating of amelioration of prostitution; and chap. x., of its prevention.

We agree with Mr. Simon that we don't see any practical definition of prostitution which could include women wishing to practise it clandestinely. There seems to be about 9,500 prostitutes, according to Sir R. Mayne, in London. There are now scarcely any “houses where prostitutes are kept.” There are only two such in London; but in 1868 there were 1,756 houses where prostitutes lodged. This shows the inutility of raids. “Those who dread (who are they?) the depopulation of England, will observe with satisfaction (surely somewhat mingled with sorrow), the resources the country commands in the reserve of bachelors and spinsters, whilst the economists will see that prudence is exercised (especially by the women) to an extent which Malthus scarcely anticipated.” It appears that there are but few “accommodation houses” in London now; there are only, he says, four or five in two or three West End parishes. Coffee houses and other places let beds which are frequently used by prostitutes. There are only 132 such “accommodation houses” in all London. Mr. Acton again informs us that there are very few deaths from syphilis. Only 127 deaths are, it seems, registered out of 3,000,000 population in 156 weeks. We don't quite agree with this view of the matter. Our own hospital experience of the diseases has shown us syphilis as the probable cause of phthisis and disease of the kidneys and liver in many cases; besides which, epilepsy and palsy are often caused by syphilis; and surely stricture of the urethra is the cause of many deaths. Of course, Mr. Acton does not allude to the infantile mortality from syphilis, always so extensive. Phagedæna, however, is now fortunately (owing to mercury and drunkenness being less common complications of the disease) a very uncommon cause of death. Most prostitutes return to honest livelihoods, and (as they have often no children afterwards) are frequently better off than virtuous or prolific women. Thus, says Mr. Acton, and in this he is an unconscious advocate of early marriages and small families as a preventive against prostitution and destitution, prostitution is in a transitory state, through which an untold number of British women are ever on their passage. Of 1,755 women at Devonport, mentioned by Mr. Sloggett, 250 had married. As regards statistics of disease, the Harveian Society's Committee of 1867 has made us familiar with the vast proportion of cases seen as out-patients at our metropo-

litan hospitals; in surgical practice frequently one-half of the cases are venereal. The army and navy, as we all know, are both infested by these contagions. How can it be otherwise so long as soldiers are unmarried, and slaves to a terrible system like the military one? The total of venereal beds is given by Mr. Acton as follows:—St. Bartholomew's, 95; Guy's, 58; Middlesex, 20; Royal Free, 26 (none at present); Lock, civil cases, 30. There are about 115 beds available for women in Woolwich and Chatham; and Dr. Stuart, of Woolwich, speaks highly of the good effects of his weekly examinations of prostitutes at Woolwich, in lessening the severity of the cases of syphilitic ulceration. But Dr. Stuart thinks there are as many clandestine as open prostitutes who are not examined. Mr. Trotter, Coldstream Guards, says that there are far more cases of venereal diseases in an equal number of men in barracks in London, where the Act is not in force, than in Windsor, where it has been applied in the proportion of 36:7 in three months. This is all rather meagre proof of the advantages resulting from the extension of the Act. Let us read in chapter v. whether there is much less disease in foreign parts.

It appears that a M. Antin of the Assistance Publique of Paris, estimated in 1856 that 20,000 women lived by prostitution. In 1854 there were 4,260 of them inscribed on the registers of the Bureau des Mœurs, 5,002 being in houses and the rest free. There are 270 beds for prostitutes at Lourecine Hospital, and 200 at St. Lazare. There are two physicians to the St. Lazare Bridewell Infirmary. The Lourecine Hospital was established, it appears, in 1836 for free venereal female patients. These may quit the hospital when they please, even before being cured, although in the latter case they are remonstrated with. Thirty *mouchards*, or detectives, haunt the streets of Paris, and according to our author receive 3 francs for detecting a diseased woman and sending her to St. Lazare. “The older prostitutes avoid contagion by examining every man who desires to have relations with them.” Most of the old prostitutes seem to regard themselves “as a class useful to the State and recognised by the police.” Of 150 patients visited by Dr. Clerc at the St. Lazare with the author, not more than two or three were confined to bed. It is believed to be almost impracticable to administer mercurial pills to prostitutes, and we think they are lucky in this, as there is a popular prejudice among them against the drug. At the police office, Rue de Jerusalem, 174,000 speculum examinations are made yearly. One woman admitted that she sometimes received as many as 40 men in 24 hours. It appears that in 1865 the effective force of the French army consisted of 348,968 men, and during the year 31,918 soldiers suffered from the disease, or 92 in 1,000, instead of 325 per 1,000 as in this country. Venereal diseases cost Paris hospitals, for 812 beds at £28, £24,000 a year. The expense of treatment of French soldiers is £60,000. Venereal diseases are much lessened in frequency in the French navy; but in the Merchant Service one-fourth of the sailors are said to be infected annually. In Belgium syphilis has almost disappeared from the Brussels hospitals. Only 42 cases were under treatment out of a population of 260,000. Formerly, there used to be as many as 150 to 160 cases in the same wards. There were but 90 venereal patients in 1,000 men during the year 1868 in the Belgian army. In Hamburg there are very stringent police regulations, and there are only 30 per 1,000 venereal cases in the army per annum. Marriage has fallen off greatly in Hamburg. In 1709 there was 1 marriage in 45 persons; in 1840, 1 in 100. In Berlin, the police system obtains. There are 1,639 known prostitutes, and about 13,000 clandestine prostitutes there in a population of 702,000. We don't hear whether Berlin is free from venereal diseases or not. The Prussian army in 1867 numbered 240,000. The average number of venereal cases is 62 per 1,000.

The average number of beds for prostitutes in Vienna is 600; of which 200 are for males. In Vienna, one in every two children is illegitimate, and in Munich there are more illegitimate than legitimate children. The Austrian State, in order to discourage over-population, says Sir W. Wilde, countenances illegitimacy. There is an immense amount of disease among clandestine prostitutes; as much as 40 to 50 in 100 of them in Paris being found to be diseased. This is the great stumbling block of Mr. Acton and his school. Are they to register some 30,000 or 40,000 women in Paris and London? Under the head of *Causes of Prostitution*, Mr. Acton truly remarks,—“We must not lose sight of the fact, that the desire for sexual intercourse is strongly felt by the male (and surely by the female too?) on attaining puberty.” But, he

adds, "Man's plain duty is to seek in honourable love the gratification of manly desire." Granted. He thinks Malthus and Mill's advice, not to breed too fast, is premature so long as the earth is in many places so empty. And yet, a little way on our author objects to Mr. Simon's plan of early marriages as a preventive of prostitution. We prefer Mr. Simon's views entirely to Mr. Acton's; but we tag on a condition to Mr. Simon's prescription, to the effect that early marriages should be accompanied by only one or two children, and that divorce should be made far more facile than at present. Mr. Acton is very fond of the Bible phrase, "Be fruitful," &c., and yet advises people to marry late. How does he reconcile this? "So ferocious is the struggle for position," he writes, "that I am more inclined to look for the sanction of society to the revival of convents, or the Malthusian modes of checking population, which prevail elsewhere (in France?), than for the rich or the poor genteel to permit their offspring to increase and multiply young paupers," &c. Quite true, Mr. Acton; it is far more likely that people will recommend small families, early marriages, and home existence to emigration, caused by pauperism, in the future, just like our highly civilized and charming neighbours, the French. Mr. Acton, of course, shows how poverty, added to ignorance, and, of course, overpopulation, is the most common cause of prostitution. Prostitutes are so barren that they don't crowd the poorhouses with pauper children, like poor married women. We wonder how it is that Mr. Acton has not studied more deeply the works of Malthus and J. S. Mill in the original. He seems to be much interested in the ideas, but not quite familiar enough with the arguments used by Chalmers, Garnier, and many of the French economists. Dr. Jeannel thinks that a weekly inspection of prostitutes is best. Mr. Acton cannot "venture to hope that the sexual passion will in our time cease to operate or diminish very materially." Agreed. It is a fixed quantity, like the attraction of gravitation. As to regulation of prostitutes, he generously intends to discard from his police regulations the class of women who live in concubinage. Why so, Mr. Acton, perhaps the police might for three francs find that such women had gonorrhœa? Indeed, young women married to old men, perhaps, should be inspected. Why not? A certain Captain Harris considers the extension of the Contagious Diseases Act to London as *very feasible*. Well! we don't agree with this gentleman; but, then, we have seen ourselves in Paris what a farce the whole affair is, and we don't care about seeing the whole female population of London snubbed by a set of *mouchards* for such a small result as that obtained in Paris. Every one knows that a lady can't sit alone on a seat in Paris without some wretched agent of the sanitary police telling her to take care and move off. We would certainly not like to be born one of the female sex in such cases. Mr. Acton is much aggrieved at Mr. Simon's protest against the Act of 1866, and at his recommendation of early marriage instead. He "thought that in the present state of crowded civilization political economists had come to the conclusion that early marriage was an evil." No. They may perhaps have come to the conclusion, not that *early marriages*, but that *large families* are an evil. Although such an advocate for the Contagious Diseases Act to the civil population, our author adds: "If prostitutes should continue to be admitted into hospitals as now, would it not be well to exact on admission a promise from them that they will not leave hospital until pronounced cured by the surgeons?" Spoken as it should be, Mr. Acton! Give them hospital accommodation and exact such a promise, and you will not require the machinery of the Act of 1866. Mr. Acton says London should have 800 venereal beds if it were as well supplied as Paris. We think it would not require more than 500. It is a curious fact, which has been lately mentioned to us by Mr. Holmes Coote, that there are not nearly so many applicants for the beds in the venereal wards at St. Bartholomew's Hospital; and the same holds true for Guy's Hospital.

In summing up our views upon the proposals made by Mr. Acton for extending the Contagious Diseases Act of 1866 to the civil population, we have to say that the army and navy are quite exceptional affairs. No other body of men have any right to have recourse to mercenary love. Prostitution, every one must see, is a grievous evil, and, like poverty, it is quite remediable. The relation between the sexes, indeed, requires to be better adjusted, so that the sexual appetite should have its normal way without causing overpopulation, or we shall always have prostitution. The French system has

a few advantages, but numerous disadvantages. It tends to lower the whole ideal of the position of women in society. If women had a vote, of course (and it seems not impossible that they may) they would insist on men being examined as well as women. The erection of *State appointed* municipal venereal hospitals would be quite sufficient to check the spread of venereal contagion—the voluntary system is quite inadequate to the task; but there is no need of any Contagious Diseases Act allowing the police to bully our poor women any more than at present. We do trust that Mr. Acton's deeply interesting and admirable work may be widely read, and attract the attention of all philanthropists. It is, we think, the best work on the subject ever issued from the press, although we entirely disagree with his views as to the necessity for prostitution, or the extension of the Act of 1866.

SCOTLAND.

EDINBURGH.

At a meeting of the Royal Society, held on the evening of the 20th inst., Professor Turner read an interesting notice of the fin whale, recently stranded at Longniddry. Its length measured 78 feet 9 inches, and its girth opposite the flipper was about 45 feet. One of the most interesting features in connection with the animal was the enormous size of the lower jaw, the inner surface of which, close to its upper and outer border, was concave, and sloped inwards, so as to admit the upper jaw within it, and measured from the angle of the mouth to the tip along the upper curved border, 21 feet 8 inches. The greatest projection of the fin, from which the animal derives its name, was 31 feet 4 inches. Although the notice was preliminary to a more extended memoir, Professor Turner entered at considerable length into the structure of the animal, to the investigation of which he is devoting as much time as he can afford. The presence of so large a whale in the Firth of Forth might be accounted for, he thought, by the fact that she was in calf. The skeleton has been secured for the Museum of Science and Art.

Dr. Matthews Duncan read a paper on "Aggregation in the Dublin Lying-in Hospital," which, he said, formed an excellent foundation for an investigation into the subject of the comparative mortality in large and small hospitals. It had been in existence for a hundred years, and nearly 200,000 cases had been treated in it. On careful examination, he found that when the hospital was empty, and contained from 800 to 1,300 patients, the mortality was 14 per thousand; when the number was 2,300, the mortality was 12 per thousand; when 2,800, the mortality was 14 per thousand; and when it rose to 3,300 it was 13 per thousand. He held these figures proved that aggregation in the Dublin Hospital did not increase the mortality.

AMONG the Scotch Bills in Parliament which have been deposited in the Private Bill Office is "A Bill for Authorizing the Corporation of the Royal Infirmary of Edinburgh to remove their Infirmary Buildings to a more suitable position, and to acquire for that purpose the site of George Watson's Hospital and adjacent lands, and for other purposes." The sum obtained for the new Infirmary is upwards of £75,000, of which £61,000 has already been paid. The amount withdrawn by those who dissent to the change of site is £1,563, only £545 of which had been paid.

A CASE of a somewhat peculiar kind was tried before the Lord Justice Clerk and a jury, and concluded on Wednesday last, in which the pursuer, Dr. William Stewart, late Principal Medical Officer in the Paraguayan Army, raised an action against M. Gelot, the holder of a bill for £4,000, granted by Dr. Stewart on the ground that he had been induced to grant the said bill to Madam Lynch, the so-called wife of Lopez, under compulsion, and under fear of his life. The verdict, after a trial of two days' duration, was in favour of the pursuer.

MEDICINE AS A REMUNERATIVE PROFESSION.

IN the present state of society, when money has a tendency to cumulate in the hands of a few, when houses of business assume colossal proportions, to the destruction of the smaller houses, when farms grow in magnitude by the absorption of their neighbours' grounds, and things in general show a tendency to run into extremes, Paterfamilias, with moderate means and several boys to be started in life, is put to his wit's end to find occupation for them of a remunerative kind. Mamma objects to the Colonies. The Professions naturally present themselves to the parental eye. Now, he finds that in “the Law” a Solicitor needs a good capital to start with; and the Bar, besides needing for success talents of a special kind, is too uncertain, too slow without aid from private resources, and too full. The Church, again, ensures but a miserable pittance to her friendless and unknown sons, her prizes falling to the lot of the well-patronized aristocrats. In the Army, the pay of the subaltern scarcely meets the expenses of the mess. The Civil Service is limited, and the Navy and Colonial Services are as bad as emigration.

The merits of Physic, as a remunerating Profession, are next discussed; but the difficulties in the way of getting reliable information are great indeed. The advantages of appearing successful in practice lead to a most unreal mode of life. The candidate for practice must appear to be, what he is not as yet, a prosperous man, and, therefore, to use a familiar phrase, keeps the best side out. The friends of the medical man are, for a like reason, ready to aid in the deceit; hence, the real state of the Profession cannot be arrived at by ordinary investigation. Lately, however, something has been done to shed some light on this inquiry. Professor Paget, of St. Bartholomew's Hospital, in endeavouring to put the prospects of students

in an advantageous light, has traced out the careers of one thousand pupils of his and his colleagues. Of these,—

23 attained distinguished success; *i.e.*, Hospital appointments, Professorships at Oxford, Cambridge, or Edinburgh, or large practices in county or large towns.

66 considerable success; *i.e.*, high position in public services, or leading practices in good positions, &c.

507 fair success, or *enough to live on* (see above and after for the real interpretation of “fair success”) and a good reputation.

124 very limited success, or, from not enough to live upon, down to absolute failure.

96 left the Profession, chiefly for other callings.

7 came from other Professions; but five of these went back again.

120 died either in practice or during pupillage.

Thus 50 per cent. make a living, such as it is, 10 per cent. obtain marked success, and 10 per cent. leave the Profession, probably in disgust.

The Medical Profession being thus shown to possess few pecuniary attractions, and likely to be shunned by the better class of the youth of our day, and their places in it occupied by a much inferior grade, it behoves us to make some investigation into the causes of this state of things with a view to a remedy.

In order to facilitate our inquiries we will examine the Profession in the two divisions into which the requirements of the people have arranged it, *viz.*, the general or family doctor, who undertakes to supply all the ordinary medical requirements of the families under his charge, and the consulting doctor, who, through his position on a hospital staff, or at a special institution (if a specialist) must necessarily have more ample opportunities for the study of disease.

Accepting, then, this very convenient and long-established division, we will examine the merits of each as to income; and first, the General or Family Doctor. As a class, even the public are beginning to see that they are not wealthy, and their tradespeople well know their struggles to make two ends meet. Their names, it is true, rarely appear in the list of bankrupts, for, being accustomed from the first to the need of rigid economy, they are very rarely spendthrifts. Fifty, or more or less, years ago, the family doctor, under the name of apothecary, carried on a lucrative trade in drugs, the profits of which, added to his practice in prescribing and supplying medicines, afforded him a very respectable income, and in many cases a large one; but the College of Surgeons, then newly established in Lincoln's-inn-fields, tempted him by its wide and easily accessible portals to become a member of that corporation, and, in later times, the railways to Scotland induced him to add M.D. to his M.R.C.S.

Possessed of these highly respectable diplomas, the trade in drugs was felt to be degrading, and the shop was soon changed into the private dispensary, or the neighbouring chemists undertook those duties by contract. Thus, the apothecary voluntarily surrendered a most lucrative branch of the Medical Profession, and the druggist stepped into his place.

Another cause of diminished income is a comparatively modern creation—the out-patient department at our Hospitals, which, by its lax manner of giving advice and medicines to all comers, acts as a serious drain on the general practitioners' sources of income.]

If to these we add a growing want of faith in physic, and the dislike to taking disagreeable compounds, we have shown a triple cause for the present depressed state of the medical practitioner's income.

Let us now examine Consulting Practice as a source of income. Does it afford a reasonable prospect of success? By no means, for although some few doctors become, in advanced life, overwhelmed with practice, even they have been compelled to spend the heyday of youth and early middle life crippled by the *res angustæ domi*; and success arrives when the time to enjoy it or to undergo its fatigues has gone by. But the great majority have to continue to battle with difficulties to the end of their days, if not possessed of independent means. Several causes combine to produce this state of things; their disproportionate numerical increase; the rivalry of the fairly educated general practitioner of the period, and the great amount of time spent in unpaid labour. The growing disproportion between candidates for consulting practice and the population is evident to every one, and we all know the quirks and quibbles practised by our family doctors to avoid a consultation if one be proposed; the division of responsibility which, in cases of danger, would seem paramount to all other considerations, is not by them considered equivalent to the loss of position which they fancy they must suffer. The losses arising from this cause are, however, generally compensated for by a little gentle pressure on the side of the patient. But the circumstances most injurious to this division of the Profession are to be found in the amount of time squandered in unpaid labour at the Hospitals and Dispensaries. The rivalry for these necessary appointments has grown to such a height that the Governors have their choice of a large number of candidates willing to act as an unpaid staff, and grateful for the appointments; the honour and glory which accompany them being, they think, equivalent to the losses they entail.

Can any remedies be suggested for such a state of things? or must the Profession be allowed to fall into the hands of a more humble class of men (at present we put lady doctors out of the question)? The family or general practitioner, having given up a lucrative branch of his business, cannot retrograde to it, even if that were desirable. Two courses, therefore, are all that remain for him—either to increase his fees, or to diminish the number of practitioners; the latter course can easily be effected by the simple plan of telling the truth and acting the truth. Let the system of deception now practised by himself and his friends be no longer followed; but let the world see him as he is, a struggling man, although a hard-working one, a man deprived of recreation and amusement, and tied to home by the nature of his Profession, with no prospect of doing more than his own personal badly-paid labour can effect. Let all this be honestly made known, and, unless mankind be greatly changed from what it now is, the number of candidates will diminish, and a system of honest remuneration for services will certainly follow.

The same remedy is, *à fortiori*, applicable to the Consulting Doctors; but for them there is an additional aid, lying in their own hands, "*Quis morietur homo cui salvia crescit in horto?*" Let them, one and all, refuse, with a true *esprit de corps*, to accept unpaid appointments. The idea that advantages, equivalent to their time and labour, accompany appointments to the smaller Hospitals, and

especially the Dispensaries, is now pretty fully exploded. In no other profession does a system of unpaid labour prevail, not even in the Clerical. The workman is worthy of his hire, for the cure of both souls and bodies. No man, who is not wholly independent of his Profession for support, has a right to give his time gratuitously; it is not his to give; his wife, his children, his home, his immediate dependents, perhaps one or both aged parents have a claim on that time. "Charity begins at home."

MR. GOSCHEN AND DISTRESS IN EAST LONDON.

ALL well-informed medical men know how much the pauperism of our large cities influences the death-rate. Villermé was, in 1832, perhaps, one of the first to show that the inhabitants of the poor quarters of Paris died in a far more rapid manner than those of the richer quarters; and, certes, those who will visit the Mouffetard quarter of Paris, after quitting the Madeleine quarter will not be surprised that the deaths of the former should be greatly in excess of those in the latter. And so with London. The death rate of St. George's, Hanover square, is somewhat like 18 in 1,000 annually; and in Whitechapel, it is 28 in 1,000. Then, again, very few of the children of the rich (1 in 10) die before the age of 5; but as much as 150 in 1,000 of the children of the poor die annually before the age of 5. Consequently, of course, to the medical man, the twaddling transcendentalism which asserts that there is always some compensation in the lot of every person, however poor or unfortunate, is nothing but an ignorant assumption. Poverty, to the extent of pauperism, is an unmitigated evil, and kills more people than the light of science can ever hope to cure; since it causes fever, epidemics of all kinds, and consumption. Hence, all medical men are, as a rule, greatly interested in questions of pauperism, except, indeed, a few who are immersed in the details of the profession, and have little or no leisure to interest themselves in anything else. The conference which took place lately in Sion College to consider the desirableness of united action with a view to checking the increase of pauperism, and to improve the condition of the deserving poor, may be worth some consideration in these pages. It was suggested that, as there is likely to be a great deal of distress this year in the metropolis, it would be as well that the ministers of different denominations should co-operate as they had done in the cholera year. The difficulty of defining the limits between legal and charitable relief is felt even by the Commissioners of the Poor Law. The principle of that law is, of course, to administer only the minimum of relief. Mr. Goschen said, indeed, that he suspected that the Poor Law, even dating it back as far as Elizabeth, had done a considerable amount of damage by establishing the principle that every person, whatever his antecedents, was entitled to relief; a principle which obtained in no other country but this. It certainly has a tendency, if not watched, to cause the poorer classes to cast aside that independent character which alone makes human nature interesting or noble; and Mr. Goschen says, that in some cases quite recently, some miners have actually stipulated, on joining benefit societies, that the allowance from these societies should not be taken into account when they received parish relief. Such facts as these made Chalmers and others so

long hold out against the introduction of the English Poor Law into Scotland, and we believe that that country will not any longer be so likely to produce a Burns or an Allan Ramsay as it formerly was since the introduction of this Act. It is evident, then, that the Poor Law should not, in any way, attempt to subsidize private charity. It should be entirely oblivious of the existence of all such charities, and should act systematically and without distinction of persons. A *minimum* of relief is all it should ever give. It has been proposed that an accurate register might be drawn up in London of all who are in receipt of either pauper or charitable relief. This we don't think is feasible, and we can't see what the Poor Law Guardians have to do with private charities at all. "The quality of mercy is not strained." Charity may be employed as the donors please; but the parish have nothing to do with charity; it has only to see that the Poor-law is carried out. There are, it seems, about 150,000 paupers in London at present, and Mr. Goschen says that not much more than 3,000 of these are able-bodied men, the rest being old, sick, and infirm men, and women and children. We don't exactly see why women are to be classed with old and infirm men. A woman, when in good work, can, we all know, often earn admirable wages; and if there are so many working-women out of employment, it is a question, worthy of most serious consideration, why this is the case in London. In many parishes the Guardians take advantage of the charities existing in them to give only out-door relief, trusting to the poor to get more from these institutions; but why should these parishes be allowed to do what the others cannot do, *i.e.*, evade the law on this account? The law of the land fixes no bound to the amount of *adequate* relief which the parish is compelled to give to all of its poor, and rates *must* be raised for this purpose. We believe that it is infinitely more economical in the long run to give adequate legal relief than to pauperize the poor by allowing them to keep at home at wretched wages, partly supported by the charities, and partly by miserable doles from the workhouse. This view of the matter has, until recently, always been taken by all well-informed Boards of Guardians. We cannot help, then, pointing out how important it is these Boards of Guardians should henceforward, in London as elsewhere, abandon this illegal way of giving out-of-door pittance to healthy persons, and determine in future to cause all such persons to enter the walls of the "house" before receiving any relief. The only exception at present to the strict carrying out of the law ought to be in the case of sickness, which naturally (so long as there are no public hospitals, like those of Paris, where ALL sick persons are entitled to enter), gives a claim, especially in such a large city as London, to public relief even out-of-doors.

One of the great causes, however, of all this miserable tinkering in London, must be looked for in the inadequate distribution of poor-rates throughout this big city. The saying that "from the poor shall be taken away even that which he hath," is exemplified every day in the history of the Poor Law taxation of the metropolis. How is it, we ask, that the parishes in the East end of London put up with this inequality? Verily, they are long suffering and slow to wrath, for it would be quite impossible to keep up the shameful inequality of rating, which exists between Whitechapel and St. George's, Hanover square, for even a year longer, were the poorer parishes but to press their claims earnestly for one Session of Parliament. Every city

should be taken in its entirety in all questions of poor rates, and there should be an entire equalization of rates throughout the metropolis from Hammersmith to Bow, and from Highgate to Camberwell. The way in which Paris is managed excites our envy and admiration more and more every day. But the spirit of mere routine is so great, and our citizen of London conceit so great, that it may be some time before we shall try to imitate that city in dividing London into districts, each with its local government and with a central government represented by the mayors of each quarter and some other delegates. As to Dr. Stallard, who spoke the other day at St. Saviour's, if he is correctly reported in saying that the State should provide a machinery for a thorough house-to-house visitation of all who are in receipt of any kind of charitable relief, we cannot understand what he supposes the province of Government ought to be. Dr. Stallard is quite outrageous in his desire for State interference. That we should all be compelled to send our children to school, or to vaccinate them; to abstain from injuring our neighbour, or from committing nuisances of many kinds, we are ready to admit, and strenuously to maintain; but the limit of State interference with individual action is very soon reached, and this extension of it proposed by Mr. Stallard would turn us into a bureaucratic-ridden people in a very few years; and if, in addition to this, the police are to regulate prostitution, and perhaps to shut up public-houses, we may have to emigrate in order to find individual liberty alive. The main principle of human life is, that every person must work in order to live, and if we except sick people and infants, it is as much as we ought to do. To do more than give a minimum of subsistence to any other person, is a grave crime against the workers who must work to support them in idleness. We, then, in conclusion, would urge upon the supporters of the various London charities, to combine together and organise the whole of the charities of the metropolis better. To the Guardians we would say, "Act as if there were no charities in London. You have no business with *charity*, but only with *adequate* legal relief to all who apply to you for it and are legally entitled to it."

Notes on Current Topics.

Medical Reform.

THOSE who hoped for a Government measure next Session have now nothing left but to resign themselves to disappointment. Few who know the reluctance of statesmen to interfere in professional politics will be surprised at the announcement that the Cabinet has too much on its hands to take up a Medical Reform Bill. Sir John Gray's Bill will, therefore, come before the House with a still greater chance of full consideration. We believe that Sir John will make a strong effort to carry his measure, of which we some time ago foreshadowed the leading features.

Nearly all the medical M.P.'s, including Sir John Gray, as well as eminent statesmen of all parties, have expressed their approval of the reform of the Medical Council advocated by Dr. Prosser James. It is, therefore, probable that this desirable reform will be carried by the coming Bill. To such a reformed Council, truly representative of the Profession, as well as of the Universities and corpora-

tions, the Government would be willing to concede those larger powers which they will not entrust to the existing oligarchical Council. Here, then, is an additional reason for reforming the Council. What a pity that body had not sufficient self-abnegation to effect for itself what must be forced upon it, and thus have secured the confidence of the Profession and the public, instead of justly forfeiting it!

Death of Professor Geoghegan of Dublin.

THE celebration of the Christmas festival in Dublin has been, in professional circles, somewhat marred by the melancholy and unexpected death of Dr. Geoghegan, well known to our readers as one of the first existing authorities on forensic medicine, of which subject he held the Professorship in the Royal College of Surgeons in Ireland. The sudden death of a very near relative a few days ago had fallen with great force upon him, but on Christmas morning he appeared to be in his usual health and spirits. On coming out of his bath he fainted; and when the assistance of his friend and colleague, Professor Benson, could be obtained, he was found to be quite dead. Professor Geoghegan's great talents have always ensured himself a place in the high esteem of the Profession; and on several occasions recently his name was mentioned as that of a probable occupant of the Presidency of the Royal College of Surgeons, of which body he has been a Fellow since the year 1830. To his rank and position as Medical Jurist, there exists in Ireland no as worthy successor, and the College has in him lost one of those members who have created and added to its prestige throughout the world. By Dr. Geoghegan's death a Surgeoncy in the City of Dublin Hospital and the Hospital for Incurables, in addition to his Professorship, becomes vacant, as well as the position of Medical Adviser to the Royal Insurance Company in Ireland.

Hysterical Aphonia.

DR. TANNER says that he never fails to cure this obstinate nervous disease by means of electro-magnetism. He places the patient in a chair, gives her one handle of the instrument moistened into her hand, and with the other touches the tongue. The patient then screams out violently, and thus convinces herself and friends that she has not lost her voice.

Proposed Royal Society of Medicine.

THE delegates from the various societies met on the 13th, and most of the clauses in the draft submitted to them from the Medical and Chirurgical Society were approved of. The section of Anatomy and Physiology was, however, unanimously condemned.

Vaginismus.

DR. TILT protests against the necessity of using the knife or scissors in this comparatively common condition. He places the patient under chloroform, separates the two thumbs which are back to back in the vagina, and keeps the vagina distended for five minutes. He then introduces a large metal bougie, and keeps it in by a T bandage for several days.

THE illustrious Professor Czermac is at present on a visit to this country.

The Health of Ireland.

THE Quarterly Return, published by authority of the Registrar-General, has just been issued, and it includes the births and deaths registered during July, August, and September, 1869, in the 781 Registrars' districts of Ireland. The births registered during the third quarter of the present year amounted to 34,058, affording an annual ratio of 1 in every 40·6, or 2·46 per cent. of the population, the average during the corresponding quarter of the years 1864-8 being 34,048. There were 18,685 deaths during the quarter ending 30th September last, a number affording an annual ratio of 1 in 74·1 or 1·35 per cent. of the population. The average during the corresponding quarter of the years 1864-8 was 18,803.

It is evident from the foregoing figures that the registration of births and deaths is very imperfect, the annual ratio of births to the estimated population in England being about 1 in 29 or 30, and of deaths of 1 in 44 or 45; whilst in Ireland, according to the present return, the ratios are, for births, 1 in 40·6; and for deaths, 1 in 74·1. The registration of marriages is still more unsatisfactory, the number of births being 34,058; the deaths 18,685; and the number of emigrants 16,254, a decrease of 881 would appear to have taken place in the population of Ireland during that period.

The number of deaths amounted to 18,685, contrasting favourably with the mortality in the corresponding periods of the previous five years, when the average number of deaths was 18,803.

Scarlet fever was the most prevalent of zymotic diseases. Sixty-two of the Registrars refer to this disease in their notes. The North-Eastern Division suffered most from scarlet fever, deaths from this disease having been reported from twenty-eight Registrars' districts. Of the 61 deaths registered in Keady, 12 resulted from scarlet fever, and 3 from diphtheria. In Castlereagh 138 deaths were registered; the Registrar states that "during the quarter 48 deaths occurred from scarlatina, the district having been visited by an epidemic of a very malignant character." In Ballybay, one-fourth of the deaths was ascribed to scarlet fever, and Drogheda suffered much. The Registrar states that "the sanitary arrangements of the district are very deficient."

The prevalence of measles and whooping-cough was reported by many Registrars.

The deaths from typhus and typhoid or enteric fever were numerous. The sanitary arrangements of the districts visited by fever were, in nearly every instance, most defective. The Tipperary Registrar, referring to the prevalence of fever in the town, remarks, "This I attribute to the overcrowded, filthy, and neglected state of the houses of the poor, and more especially their unwillingness to send to hospital cases requiring prompt removal. Such occurring in quarters where the destitute poor chiefly reside, and where sanitary arrangements to secure cleanliness and good sewerage are sadly neglected, the wonder is that we are not more frequently visited by zymotic diseases. I do think that until the sanitary code is rendered as compulsory in the district as the Vaccination Act, it will be impossible to prevent those nuisances that usually are in close proximity to the doors of the poor," &c. The Registrar reports as follows:—"Nothing can be worse than the sanitary state of the village of Goleen. There is but one well, and this is kept in a most disgusting way. There are

seven occupied houses in the village, and during eleven years there have been about 30 deaths, and we had neither fever, famine, or cholera. At Rock Island (a village under the Government), about two miles from Goleen, where sanitary measures are well carried out, there are eleven houses, with large families in each, yet, during *thirty-one years* there were but 8 deaths, and those thirty-one years included the famine, fever, and cholera years."

No death from small-pox was returned during the quarter.

From various parts of the country most favourable reports have been forwarded by the Registrars as regards the benefits resulting from the successful working of the Compulsory Vaccination Act.

"Dark Sam, the Medical."

THE above is the title of a chapter in the new Christmas novel, "Brilliant Prospects," by R. L. Johnson, which we have read with deep interest. As the novel in question has met with the approval of the *Athenæum* and other leading literary organs, we need not allude to any of its merits, but merely say that in other parts beside this chapter there are indications of the author's familiarity with medical men and customs that almost make one fancy he must himself have studied the profession. "Dark Sam, the Medical," is only an episode in the story, so that if we say something about him we do not spoil the plot for our readers. It relates the career, at a Dublin School of Medicine, of a medical student, who, several years ago, was addicted to flirtations, which, on several occasions, nearly got him into serious trouble. He escapes from several fair ones by ingenious excuses, and a very strange trick of making himself scarce at the very crisis of his love making. He was at last, however, hooked and landed, as all such slippery fish ought to be, and the secret that haunts him afterwards is told in a most comical way.

Our weary brethren looking for an amusing book this Christmas time should get "Brilliant Prospects."

Medical Society of London and Athletic Sports.

ON the 20th inst., at a very numerously attended meeting of this society, a most interesting paper was read by Dr. Farquharson, formerly of the Coldstream Guards, on the effects of athletic sports on the system. So far as the too brief limits of the paper allowed, the relative merits of walking, running, rising, and rowing were discussed; and then the author enlarged at some length on the game of football as played at Rugby, and he described some of the various accidents that had come under his notice as the results of this form of athletic exercise. Considering the exceptionally violent and rough way in which football appears to be played at Rugby, it was remarkable to hear how few immediately serious injuries had come under notice. Cases of fracture of the metacarpal bones, of severe injury to the shin bone, and to the ligamentum patellæ were mentioned, as well as a distressing case of injury to the cervical spine, from the neck being so violently bent forward that the lad's nose touched his chest. This case had symptoms of paraplegia for a time; but these had, in a measure, passed away, and things had assumed a more favourable aspect. The patient is still under treatment.

An active discussion ensued on the termination of the

paper. Mr. Dunn regretted that the author had not made mention of fencing as a sport eminently calculated to educate every muscle in the highest way possible.

Some apt remarks were made by Dr. Simms on the intense folly of training men on an exclusive diet of beef-steak; this was just the same as if a steamer were prepared for a long voyage by making its piston rods of double strength, while no thought was taken of putting coal into the fires or water into the boiler. Dr. Richardson, in a vigorous and athletic speech, denounced all violent pastimes and sports as remnants of blue paint and savagery; and he alluded to the effect of rowing races as a great cause of permanent excessive cardiac development, with various systemic troubles that would arise from an over-developed heart.

Some interesting remarks were made by an Army Surgeon on the effect of the introduction of athletic exercises into the Army; it certainly was a question if the soldiers of the present day were equal in physique to the veterans of Waterloo and the Peninsula. It was mentioned that the time appointed for what was called the "running drill" was immediately after the men had had their dinners; but on the speaker representing that this practice was not unlikely to cause indigestion, the time for this exercise was changed. The sense of the Society generally seemed quite in favour of a moderate indulgence in athletics. It seemed a pity no fox-hunting doctor was present (for there are fox-hunting doctors as well as fox-hunting parsons) to put in a word for this manly and life-renewing exercise.

Horace has said that,—"*Post equitem sedet atra cura*;" but even if "black care" does settle himself behind the horseman at starting, we doubt very much whether he manages to keep his seat over the hedges and ditches, and we certainly never heard of him as in at the death.

SCARLATINA rages in Marylebone. In November, it carried off 34 persons, 23 of whom were under the age of five.

A DONATION of £1000 has been received from "H. G." by the East London Hospital for Children, at Ratcliffe-cross.

THE total number of deaths from fever in the Mauritius from 1867 to October, 1868, was probably not less than 48,000 out of a population of 350,000.

MR. WILLIAM ADAMS has divided subcutaneously the neck of the thigh bone within the capsule ligament, by means of a fine saw. This is a great triumph of subcutaneous surgery, as the case is doing well.

AT a recent meeting of the Royal Medical and Chirurgical Society of London, Mr. Pollock, of Guy's Hospital, related eight cases of amputation at the knee-joint. He thought that on the whole this operation was less dangerous than amputation through the lower third of the thigh.

THE following are the probable arrangements for Friday Evening Lectures at the Royal Institution of Great Britain, Albemarle street, Piccadilly. Lectures will be given by Professors Tyndall, Odling, Ruskin, Carpenter, Clifford, Colonel James, J. Reid, Esq., Professor Sylvester, Mr.

Peter Barlow, and Professors Rolleston, Roscoe, and Huxley. These lectures will all be delivered before Easter; and after Easter there are to be lectures by Professors Blackie, Williamson, and Odling. The lectures are at 8 P.M., and persons are admitted to all the course of lectures, from Christmas to Midsummer, for two guineas.

SIR JOHN FIFE, himself a most successful operator for stone, has lately been operated on by Sir W. Fergusson for calculus. We rejoice to hear that there is every prospect of his recovery.

M. PEAN, recently related to the Academy of Medicine at Paris that out of ten cases of ovariectomy performed by him, seven had lived. This is a great advance in French surgery.

THE Barking Creek people have been lately complaining of the London sewage rendering their town unhealthy. It appears, however, that there are many cesspools in the town, which are far more injurious to health.

At the Clinical Society on Dec. 10th, Mr. Cooper Forster and other surgeons spoke very favourably of torsion of arteries as a method of arresting hæmorrhage. The artery is seized between the blades of the forceps used for holding needles, and then turned rapidly round on its axis four, five, or six times, so as to rupture the internal and middle coats. The groove for holding the needle is better left out in such forceps.

WE are glad to see that Mr. Lowe, in a recent dinner at the Royal Society, on St. Andrew's Day, remarked that literature had an unfair advantage in competition with science, and recommended the opening of the Fellowships at the Universities to students of science. We quite agree with this. Science is the true regenerator of the human race; whereas literature is only the art of expressing what is known in an agreeable way.

THERE is a case of enlargement of the liver in a young man, aged twenty, in Guy's Hospital, in which the liver appears to be enlarged from scrofulous deposit. In the Metropolitan Free Hospital, also, a case of immense increase of the size of the liver, probably from syphilis, is at present to be seen, under the care of Dr. C. Drysdale and Mr. J. Warner. In both cases the liver descends as far as the umbilicus.

IN the Pathological Society, on Dec. 7, Dr. Murchison exhibited a specimen of impacted gall stones. The symptoms observed during life were repeated attacks of colic, pain, and sickness afterwards, and latterly jaundice. The rupture of the duct caused death. Dr. Pye Smith showed a case of suppuration of the heart, probably caused by syphilis. Mr. Pick showed a tracheotomy tube which had remained two years without removal in a man's trachea. Dr. Leared showed the cancerous lung of a patient admitted into the Great Northern Hospital for phthisis. The upper two-thirds of the right lung were invaded by cancer of the encephaloid kind, and cancer cells were seen in the sputum.

THE Profession will learn with great regret of the dangerous illness of Dr. Croker, Physician to Dr. Steevens's Hospital, Dublin. We understand, and we receive the information with much concern, that little hope is entertained of his recovery; and should he unfortunately be removed from amongst his professional brethren, his loss will add one more to the sad list of deprivations which medicine in Ireland has recently suffered.

MISS GARRETT has passed with *bien satisfait* the third examination for M.D. at Paris. A medical contemporary, who is rather fond of intolerant writing, tells us that the Medical Society of Philadelphia, U.S., has recently excluded from its fellowship all medical men who teach physiology to women, or consult with them. This rather intolerant proceeding, which pleases the above mentioned writer apparently, would, of course, exclude MM. Wurtz, Baillon, and Lutz, in Paris, as well as Dr. Hughes Bennett, Dr. Alexander Wood, &c. The Philadelphia society is much in need of having a copy of a very celebrated essay on "Liberty" sent to them for their perusal, otherwise their society may become, like the paradise of Puritans, a place to which most people with any love for their kind would not like to go. *In omnibus caritas.*

A RECENT issue of the *London Gazette* informs us that Colonel Lord Strathairn, Commander of the Forces in Ireland, has, with the approval of H.R.H. the Commander-in-Chief, selected Dr. J. Marmaduke Taylor, of the Royal Horse Artillery, to fill the office of Assistant-Surgeon in the Horse Guards Blue, now so long vacant. Dr. Taylor has seen twelve years of service. While serving in India he volunteered for the Chinese expedition, and was present at the siege of Peking and the taking of the Taku Forts, for which actions he received a medal and two clasps. Dr. Taylor, as well as his brother, the late Dr. A. H. Taylor, whom the Profession will recollect as having obtained the Legion of Honour and Medjidie Decorations for distinguished services in the trenches before Sebastopol, received his education in Dublin, and was a Fellow of the Royal College of Surgeons in Ireland.

SPECIAL CORRESPONDENCE.

BIRMINGHAM, Dec. 26.

THE health of Birmingham, which has for some years past been so good, will this year show a still further improvement. When the Registrar-General's returns are issued, Birmingham will most probably stand as the healthiest of the large towns for the year 1869. This will be due to the very low death-rate of the summer months, when the weekly returns were several times at rates varying from 16 to 17 per 1,000. The last months have, however, not been so healthy. Typhoid fever has been very prevalent, but the scarlatina epidemic has been comparatively slight.

It is a remarkable coincidence that Birmingham, with its defective water supply, should have a death-rate so much lower than Glasgow and Manchester, with their pure waters. It is another link in the long chain of evidence which proves that the rate of mortality in any town is the product of many concurring causes. Here about one-half the population is supplied from well waters containing in very many instances from 20 to 48 grains of organic matter per gallon. Such a state of things calls loudly for the

interference of health authorities, and the permanent suppression of these noisome pumps. Unfortunately, at the present time there is a difficulty in obtaining an adequate water supply, and the Town Council has recently appointed a Committee to report on the subject. There is a strong party in the Council anxious to purchase the waterworks from the local company; but the present moment is an unfortunate one for such an undertaking, as the purchase would be at the highest rate on account of the large profits of the company of late years, and the Corporation would undertake the supply of the town at a time when one of the main sources of supply, the river Tame, has to be cut off, and artesian wells seem to be the chief means at command. The Committee of the Council will, it is to be hoped, in the interests of the public, sift the subject thoroughly, and bear in mind, that if the Corporation does undertake the supply, that the public will then have to trust their local governors implicitly, as there will be no local body to criticise the Council, as the Council now criticises the quality of the water supplied by the company.

The Medical School at the Queen's College has a larger class than for many years past, and in spite of the increase in the number of students, the supply of subjects is still plentiful. The school in this respect is greatly favoured. Last year the supply of subjects was very good, no less than thirty-two students successfully passed their anatomical examination at the College of Surgeons, and the exhibition in Anatomy of the London University also fell to the lot of a student of the Birmingham School. The Professors have determined on holding this year a College conversazione, to which all the students will be invited, and thus, it is hoped, the beginning of a closer connection than that of the lecture-room will be initiated between the students and their teachers. While wise and thoughtful considerations of this kind actuate its rulers, the College must advance, and, if rumour speaks truly, the pecuniary difficulties of past years are likely soon to end. An offer has been made to purchase the College buildings for educational purposes, and as the site is central and very valuable, it is felt that the purchase money would not only suffice to pay off all debts but would leave some £20,000 in the hands of Queen's College wherewith to seek an equally useful, cheaper, and, perchance, happier home. At present nothing is decided; in my next, I hope to announce the result of future deliberations.

Correspondence.

LARGE FAMILIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of the 8th inst. you put an interdict against discussing the above subject in its *theological* aspects, and you state that, in future, "Your correspondents must strictly confine themselves to the *medical* aspects of the subject." I venture, Sir, to think that the above interdict involves something of a dangerous sophistry. Theology is "the science of divine things;" in other words, it is the abstract symbol of practical morality, which ought to and must enter into the consideration or discussion of all the affairs of life, especially the intimate relations between man and man, and still more of those between man and woman. Therefore, the study and discussion of such a subject as the procreation of our species cannot, I think, be separated from its morality—*i.e.*, its theology. In admitting the so-called medical discussion of the subject in the style of some of your correspondents, without checking and tempering their views by the restraints imposed by morality and religion, I respectfully imagine, would seem like opening your columns to the suggestions of scepticism or infidelity, and shutting them to those of Christianity.

One of your correspondents has correctly said that this is not strictly "a medical question;" but, even if it were, I submit that it could not be discussed apart from its relations to morality, which would involve "theology." We are sworn

to practise our Profession "*Cautè, castè, et probè.*" But it is a question of social science, in which medical men, as physiologists, may be supposed to be better skilled than the laity. If, indeed, it could be defined what *are* the strictly medical aspects of the question, then I admit that we are bound to adhere to them; but in this case that is impossible, I believe; and if it be opened at all in your columns, I respectfully contend that it should be opened up fully, and not on one or two of its aspects only. In short, it should be treated as a broad question, greatly affecting society at large, and having many sides.

Whether the discussion be carried further or not, some very valuable papers have been elicited by it already, and which, I am sure, have been perused with pleasure and profit by many. I refer more particularly to those of Mr. Nourse and "A Layman," in your issue of the 1st inst., and that signed "Justitia," in the one of the 8th inst.

I am, Sir, your obedient servant,

L. T. H.

THERAPEUTICS v. QUACKERY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of the 8th inst. there is a paragraph relating an instance of a gross fraud perpetrated on the Profession and the public by a nostrum called "sweet quinine," it having been ascertained, on examination, not to contain quinine at all. It is well to refer again to it, as a peg to hang a discourse on and "point a moral." I cannot finish the quotation in the absence of any possible adornment in what forcibly illustrates the credulity of the public and the Medical Profession. The public, in their ignorance of medical matters, follow the lead of their professional advisers; but what is to be said of educated practitioners who habitually allow themselves to be led by the nose by trade puffs?

Each vendor of medicine thinks it incumbent on him "to bring out something new," which means, in most instances, calling an old thing by a new name, indicating anything or nothing. All that is further deemed necessary to obtain currency for the novelty is the countenance of some medical man of the talking genus, who, at a gathering of his brethren, brings it before them, and narrates any number of *post hoc* in support of his recommendation. I am far from saying that chemists and apothecaries should be debarred from making suggestions and advancing their trade interests by "new things;" on the contrary, I think they should be encouraged to do so, as, from their practical knowledge and acquaintance with drugs, and their behaviour under various conditions, improved processes of preparation may frequently be arrived at. But we should strongly protest against educated medical men, who take an obligation to discountenance secret remedies, taking things of the kind we allude to under their patronage. Their obvious duty is first to ascertain what it is they order, and not shelve their responsibility by adopting a mere nostrum put forward by a person who, perhaps, never saw a case of disease in his life.

This very prevalent practice should be considered nothing else than quackery, pure and simple. For a case in point we need not go farther than the almost universally used "chlorodyne," the composition of which is still imperfectly known, but supposed to contain as many ingredients as the Mithridates Electuary. One may surely ask what chance has medicine, in relation to therapeutics, of ever becoming a science if its professors and practitioners continue to use mystical remedies? It is little wonder that there should be so much incredulity as to the good done by medical attentions while such unscientific practice prevail.

Of late years the tone of medical literature has greatly tended to increase scepticism. I well recollect, when emerging from my student career with a diploma as physician, &c., the enthusiasm in my mind about Watson's "Practice of Medicine," with its matchless style and philosophic reasoning. The first thought on facing the responsibility of actual practice was, "What value are we to give our patients for the fees if, after all our studies, we limit our duties to an accurate diagnosis, and then hand them over to the nurse as the only valuable ally of the *vis medicatrix*?" This may seem all discursive, but I believe I will show that it bears directly on the point I started with.

The practice of ordering remedies we know nothing about can scarcely cure our patients unless by a happy accident, and brings discredit and doubt on medicines of known efficacy, apt

to be classified with them as part of our armamentum. We lose faith in the weapons nature and science place at our disposal to combat disease, and the public soon diagnose our want of faith, and lose faith in us. All this leads to that widespread scepticism, from which thinking studious people take refuge in those branches of medicine, physiology and pathology, which amply reward their diligent pursuit, and seem to be all in all, to the exclusion of the real end and aim of medical science—to wit, curing patients. This scepticism finds its highest development and best expression in the work I mention, and mention with reverence. From its elegance and clearness of style, it intensifies that feeling, and seems likely to perpetuate it to an almost indefinite period. This brings me back again, round the vicious circle to the point I started from—the evil consequences of ordering quack nostrums on the *omne ignotum* principle. The quackery of nostrums leads to doubt, and doubt back to quackery, and so on round. I know several highly cultivated medical friends, whom I never meet that I do not hear of some wonderful cure by a lately discovered elixir vite, and, at our next merry meeting, that the same disease “yielded like magic” to a still later invaluable remedy; the latest and best being never apparently arrived at, though always believed to be. I am always reminded thereby of the ludicrous description I once read of the disconsolate state of Beau Brummel’s valet on coming out of his master’s room with a dozen cravats on his arm, all out of fashion.

I think it is quite time that a decided stand should be made against this sort of thing, by medical men resolving to know what they order, and that good will eventuate to our Profession by turning our attention thereto.

I am, Sir, yours, &c., Q.

WOMEN PHYSICIANS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of December 22nd, I perceive that a member of the Profession in Ireland, Dr. Duggan, strongly objects to the new movement going on among our sex. Surely, the gentleman has very little knowledge of the wants and wishes of so large a class as the unmarried women of this country now constitutes. The energies which are now frittered away, in wearisome every day so-called occupations, were surely more safely and profitably directed towards the study of pursuits likely to be beneficial to others, as well as infinitely more interesting to themselves. We should, perhaps, hear less of “Girls of the Period,” were our young ladies encouraged to bend their energies towards some nobler aim than that of out-heroding the last fashions of Paris. Surely they would be far happier with some practical end before them, than remaining in a frequently miserable and profitless existence; and, instead of being discouraged by letters like the above mentioned, I think they ought in every manner to be helped onwards in a path which bids so fairly to be useful to themselves and beneficial to the community.

All I plead is, that they should have a fair trial; and, if they have, what is good in the new movement is sure to prevail. And, I may remark, that there can be no sufficient reason for keeping women out of the medical profession, as being unfit for it; surely, if such be the case, time will show this by their want of success.

With regard to your correspondent’s argument, that ladies of refined mind would shrink from the details necessary for a course of medical study, I would reply, that many ladies of the most refined mind and fastidious natures are compelled by the necessities caused by sickness in their family circle, to perform tasks of which medical men, and men at large, have very little idea. Surely, the same qualities which are so judiciously and practically exercised in private could be even better exercised when improved and directed by the systematic training of our medical schools. We see the admirable effect of proper training in the case of hospital nurses, who are comparatively an uneducated class; why, then, should social position and education disqualify a woman for the higher duties of medical practice, to which she brings the same womanly qualities which renders the less educated nurse so beneficial an attendant at the sick bed?

I should be very glad, Sir, if your correspondent would inform us, what are the many other useful occupations which are to be preferred to fill up the measure of an unmarried

woman’s existence, for, I confess, that I do not myself know of any which are so far superior as to prevent them following out the bent of their own inclinations, if these should lead them towards a course of medical study. It is not Providence which has put a bar upon the full exercise of any medical talents women may possess, but man’s laws, which have, in later ages, excluded her from this and many pursuits which she might beneficially follow, and which, indeed, in ruder ages, she filled with as much efficiency as he did.

With respect to the alleged difficulty of attending public lectures with medical students, I must remind Dr. Duggan, in the first place, that that is not absolutely necessary, as separate classes are instituted in Edinburgh at present for ladies; and, furthermore, I believe that the novelty once removed, this difficulty also, of both studying together, would disappear.

I am afraid that, in the benevolent wish of your correspondent to keep us to the study of “poetry, of music, painting, languages, and literature,” he has rather forgotten that women must live; and as I fear the fine arts in the present day are not a very marketable commodity, perhaps we may be allowed to try something which would be more likely to supply us with the necessaries of existence. We know already that some female physicians are in the receipt of handsome incomes, and we should like very much to be allowed to follow their example without narrow-minded obstructions being thrown in our way.

From all of these considerations, I trust, Sir, that the arguments used by Dr. Duggan may fail to retard the movement, which I hope may end in the entrance into the profession of many educated ladies.

I remain, Sir, your obedient servant,
London, 27th Dec. 1869. ELIZA ARNOLD.

Obituary.

THE LATE MR. JOHN GAY, M.R.C.S.

The deceased died at the early age of forty-nine. He practised, as did his father and grandfather before him, at Swindon, Wiltshire. He was much esteemed by all who were acquainted with him.

THE LATE MR. G. C. KENRICK, M.R.C.S.

MR. KENRICK died at Seend, Wiltshire, in his sixty-fourth year, having suffered from paralysis of the lower extremities for four years past. For the last thirty-five years he had established his practice in Melksham, and enjoyed a most extensive and lucrative practice in that town. He was much beloved and respected as an able practitioner through the whole of North Wilts.

EXTRAORDINARY RECOVERY FROM EXTENSIVE SAW WOUND OF THE SKULL.

Dr. A. C. Fulsom relates the following:—A man received a dangerous wound of the head from a circular saw, and was seen by him in about half an hour, when he found the condition of things to be as follows:—The wound commenced at the frontal bone, half an inch above the nose, and extended a little to the left and a little below the occipital protuberance, passing through the superior edge of the parietal bone. Measured by the convex surface of the skull, the length of the cut in the bones was nine inches. They fell apart over an inch—the length of the scalp wound being eleven inches. The membranes of the brain, as well as its substance, were divided, the former much lacerated, and the latter falling apart sufficiently to admit a common pocket rule to the depth of one and a-half inches, and a small silver probe two inches, before touching the walls of the cut. Thirty-two minute pieces of bone, together with considerable sawdust, were taken from the wound, also a tablespoonful of the substance of the brain. No large arteries were severed, and the patient did not lose over two ounces of blood. The pulsation of the cerebral arteries could be distinctly felt, and there was no congestion of the brain or its membranes. The pulse 72. No pain or undue sensitiveness about the wound. The patient could not tell when the brain, membranes, or walls of the cut were touched, but the scalp was

sensitive when handled. The cranial bones were brought in apposition by placing a tourniquet around the head, and gradually tightening it. The scalp wound was brought together by sutures, places being left for the exit of pus. The sutures were removed on the eighth day, and the wound healed by first intention, except at the places purposely left open. There was no cerebral disturbance, and no medicine required. He was dismissed at the end of three weeks, and in five or six weeks from the date of the injury he was again at work in the mill.—*Pacific Medical and Surgical Journal.*

GLYCERATE OF TAR.

The excellent effects of tar in skin diseases leads us to call attention to the elegant preparation called glycerate of tar. Its preparation is thus described by Mr. J. B. Moore, in the *American Journal of Pharmacy* :—

Glycerine seems to be a good solvent of the medicinal properties of tar, and possessing demulcent, alterative, and nutrient properties, serves as a valuable adjunct to the latter therapeutically.

I will now present the formula which I have adopted, after repeated trials, as the most desirable for the manufacture of this preparation :—

R Picis liquidæ (strained), ℥j. troy.
Magnesiæ carb. (rubbed
to powder on a sieve), ℥iij. ,,
Alcoholis, ℥ij.
Glycerin, ℥iv.
Aquæ, quantum sufficit.

Mix the alcohol and glycerine with ten fluid ounces of water. Rub the tar in a mortar, first with the carb. magnesia gradually added, until a smooth pulverulent mixture is obtained; then gradually add, in small portions at a time, with thorough trituration continued for fifteen or twenty minutes, six fluid ounces of the mixture of alcohol, glycerine, and water, and strain, with strong expression; return the residue to the mortar, and repeat the trituration as before, with five fluid ounces more of the same liquid, and express; again treat the dregs in the same manner with the remainder of the menstruum, and after expression reduce the residue by trituration to a uniform condition, and finally pack firmly in a glass funnel prepared for percolation, and pour upon it the expressed liquors, previously mixed, and when the mixture has all passed from the surface continue the percolation with water until one pint of the liquid has been obtained.

When first prepared, the "glycerate" is of a beautiful rich reddish-brown colour. After a short time it loses, in a measure, its transparency, in consequence of a separation of *inert* pitchy matter. But its pristine beauty may be easily restored by filtration, which is accomplished in a few minutes, as it passes the filter very rapidly. This deposit of resinous matter continues for a considerable lapse of time, but does not diminish or impair in the slightest degree the medicinal virtues of the preparation, but simply temporarily mars its beauty.

It possesses in a high degree all the sensible properties of tar. In this they are more strongly marked than in any preparation of tar, excepting the tincture, I have seen.

In conjunction with the fluid extract of wild-cherry bark, acetate, or syr. squills, syrups of guinaria, lactunas carium, &c., in varied proportions to suit the views of the prescriber, it will form elegant and palatable combinations, which will be peculiarly adapted to the treatment of chronic coughs, and the various diseases of the pulmonary organs.

Each fluid ounce of the glycerate, if the process has been carefully managed, will represent about thirty grains of tar, the dose of which is from a dessert to a tablespoonful.

The glycerate may be made, and I think almost equally well, without alcohol, by replacing that liquid with glycerine. When made in this way, the preparation deposits less resinous matter, as glycerine takes up less of that substance, yet the odour and taste of the tar is nearly as strong as when alcohol is employed in its manufacture.

A CASE OF POISONING BY THE OIL OF TANSY.

As cases of poisoning by oil of tansy, are not, I believe, of very frequent occurrence, I thought it might be of interest to note a case with which I came in contact recently.

On the 24th of August, Mrs. ——— consulted me regarding her daughter's health, a prominent symptom being a cessation of the catamenia. I prescribed a chalybeate mixture, and saw nothing more of my patient until the 27th of September. Her

appearance then aroused suspicions, which I confided to her mother. I visited her next morning and, after a careful examination told her I believed her to be *enceinte*, which she strenuously denied. That evening a messenger summoned me saying that Miss ——— was "in a fit." I found her perfectly unconscious, though not profoundly comatose, pulse feeble and somewhat frequent; pupils slightly dilated. I fancied that I could detect a faint odor of tansy on her breath; but her mother told me she had been drinking camomile tea, and had not had any tansy. I gave her a mixture containing ammoniated tincture of valerian, determining to return shortly. On doing so in about half an hour, I found that she had vomited a little, and the odor of tansy was now too strong to be concealed. I managed to get her to drink some warm water, thus keeping up the emesis, ordered an enema of mustard and water, and afterwards gave her castor oil, suspended in milk. In a couple of hours she was so far recovered as to be able to talk. The next morning all symptoms were gone, except some lightness and pain of head.

I was afterwards informed that before my arrival the patient had been frothing at the mouth.

She asserts that the quantity taken was not over half a teaspoonful: that it was obtained (from a druggist in a tumbler) there being only the one dose. As she refused to give the name of the druggist, further investigation of the subject was prevented.

I may add that no uterine disturbance has ensued; and that the calculations of the patient now agree with physical signs, confirming my opinion that she was between four and five months gone when the abortion was attempted Dr. Aldright in *Canada Medical Journal.*

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—At the annual election meeting of the Royal College of Physicians of Edinburgh on Thursday week, the following office-bearers were elected for the ensuing year :—

President.—Dr. Andrew Halliday Douglas. Council.—Dr. John Moir, Dr. Robert Bowes Malcolm, Dr. Alexander Wood, Dr. Robert Paterson, Dr. James Matthews Duncan, Dr. William Sanders. Vice-President.—Dr. John Moir. Examiners.—Dr. Bell, Dr. Wood, Dr. Douglas, Dr. R. Paterson, Dr. Wright, Dr. Keiller, Dr. Pattison, Dr. Gamming, Dr. Duncan, Dr. Haldane, Dr. G. Balfour, Dr. Struthers, Dr. Ritchie, Dr. Stewart, Dr. Linton, Dr. Muirhead, Dr. Angus Macdonald, Dr. Fraser. Treasurer.—Dr. Samuel Somerville. Secretary.—Dr. Daniel Rutherford Haldane. Curator of Museum.—Dr. William Henry Lowe. Librarian.—Dr. James Warburton Begbie.

INDIAN PRISONS.—The number of persons in jail every day throughout India is about 74,000. Dr. J. L. Bryden annually publishes statistics of the health of the prisons in Bengal, the North-Western and Central Provinces, Oudh, and the Punjab. The daily jail population of these provinces numbered 55,237 last calendar year, to which figure the number of prisoners has gradually increased since 1860, when it was 46,348. But, contrary to Miss Carpenter's imaginings, the health of the convicts has steadily improved as their numbers have grown. In 1860 the number daily sick was 57, and the mortality was close on 111 per thousand. In 1863 the daily sick were only 29, and the death rate so low as 30½, a rate which we believe to be below that of the ordinary native population. The improvement has been steady year by year. Even when the famine in Bengal crowded the prisons with emaciated creatures, the death rate rose temporarily from 57½ in 1865 to 62 in 1866, and fell to 38½ in 1867. What cholera is to the English soldier typhoid fever seems to be to the Asiatic convict, and from this the jails were almost entirely free last year. The jail disease is dysentery, which carried off more than a third of all those who died. Fever ordinarily causes more sickness but less mortality. Looking at the jails according to Provinces, the death rate per thousand has varied in the ten years ending 1863 as follows :—In Lower Bengal and Assam it has fallen from 105 to 53; in Behar, Cawapore, and Oudh, from 115½ to 28½; in Central India, from 81½ to 27½; and in Agra, Meerut, and Rohileund, from 86½ to 16½. In the Punjab the rate has varied from 22½, rising to 81½ in the memorable attacks of 1861 and 1864, to 12½ last year. Even including epidemics, the improvement due to very expensive sanitation has been enormous, and it is steadily going on. Our convicts are now better cared for than the British soldier used to be.—*Homeward Mail.*

GUY'S HOSPITAL.—The annual series of concerts in aid of the Samaritan Fund was given at the above Hospital on the evenings of Wednesday, Thursday, and Friday last, before select and fashionable audiences. The musical and general arrangements were undertaken by Messrs. Buchanan and Passmore, who acquitted themselves to the most complete satisfaction. Indeed, the entertainments throughout were capital specimens of the almost perfection to which amateur talent properly directed can be brought. Space will not permit of detail, but if special commendation is due to any, in so exceptionally good a body of performers, we would mention Messrs. Passmore, Dunnage, and Palmer. Much praise is also due to the instrumentalists, to whose excellent manipulation the success of the performances is in a great measure attributable.

NOTICES TO CORRESPONDENTS.

"ERGOT OF RYE AS A THERAPEUTIC AGENT."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—If your correspondent, "N. T. T." in this day's paper, will look to MEDICAL PRESS AND CIRCULAR of 1st inst., he will find a short paper by me, containing all the particulars he requires relative to the "Liq. Ergotæ" referred to by Dr. Waring Curran.

Since then I have had several letters from medical men attesting its value. Dr. W. Curran writes to me that it is "energetic and sure," which expresses in two words all that is needed.

If "N. T. T." will communicate to me his address, I shall be happy to send him some of the "Liq. Ergotæ," that he may test it in his own practice. Your obedient servant, EDWARD LON G.

Dublin, Dec. 15.

DR. LUTHER ON THE CAUSATIVE AGENCY.

To the Editor of "The Medical Press and Circular."

SIR,—In consequence of the reference which has been made by Dr. Luther to me, as an authority on the subject of the properties of permanganate of potash, I venture to intervene with a word or two in the discussion between him and Dr. Mulvaney.

Since the date of my correspondence with Sir Joseph Olliffe, I have seen reason considerably to alter my opinion as to the inertness of the hydrated binocide of manganese, which is formed when permanganate of potash in solution is decomposed. In the finely divided state in which it is first generated in solution, I have found this substance to possess very considerable oxidizing activity. The best proof of this is the energetic manner in which it oxidizes aniline, and forms therewith almost everyone of the series of coal-tar colours. This circumstance furnishes a satisfactory answer to the remark of Sir Joseph Olliffe, that "the deodorizing effects were very apparent in the case of the patient above alluded to, notwithstanding the decomposition of the salt, a question may therefore arise as to whether the binocide of manganese itself may not be antiseptic (disinfectant).

When, however, the hydrated binocide of manganese is collected from solutions in which it had appeared as a precipitate, and is dried, its active properties are almost entirely lost; it becomes nearly inert, but not quite so inert as the native binocide of manganese. The latter, and not nascent hydrated binocide of manganese, is evidently the substance referred to by Dr. Luther, when he says, "Many preparations are in use in France; but I believe the binocide is considered inert," for the only binocide of manganese hitherto used in France or any other country has been the native. Had he been aware of the differences observed by me in the properties of the several binocides, he would not, it is to be presumed, have added, "To which condition the permanganates are reduced by admixture with oil or sugar," since they are not reduced to the condition of the native binocide.

Oxide of manganese in these several states differs also remarkably in its solubility. Strong sulphuric acid in the cold, will not act at all upon the native binocide, whereas the hydrated binocide as it is generated in solutions from permanganate by decomposing agents, is easily acted upon by many feebler acids. In the latter state it even forms definite compounds with several organic bodies, among which are sugar and albumen.

Yours obediently,

H. B. CONDY.

Battersen, 24th Dec., 1869.

PERMANGANATE LOTION IN SLOUGHING ULCER.

To the Editor of "The Medical Press and Circular."

SIR,—Might I be permitted to ask Mr. Nourse to be good enough to favour your readers with some details respecting the "dressing with a lotion of liquor calcis permanganatis," under which the case of sloughing ulcer published in your number of 22nd Dec., "made more progress than under any other dressing?" Considering the above circumstance, and the uselessness of the various applications consisting of sulphate of copper, opium, poultices, strong nitric acid, and nitrate of silver, which had been previously employed, it would be instructive to know the strength of the successful lotion, and the particular way in which it was applied; also on what principle the calcic permanganate, which is not in the pharmacopœia, was preferred to the potassic which is, and to Condy's Fluid (the sodic) which is cheaper and stronger than either.

Yours obediently,

CURIOSUS.

25th Dec., 1869.

THE REMOVAL OF DR. GOLDING.

To the Editor of "The Medical Press and Circular."

SIR,—The removal of Dr. Golding by sealed order on the part of the Poor-law Commissioners, for neglecting to reply to letters of the Registrar-General, must excite very considerable surprise and indignation. The duties of medical officers are quite distinct from those of registrars, and ought to be so considered, and it by no means follows that the registrar should be a medical officer, or a medical man at all.

Fortunately, the Poor-law Commissioners themselves are bound by the laws, and when they take such a very peremptory step as to dismiss

a possibly most efficient medical officer for an alleged neglect of some duty outside the duties of that office, and under a different government to that of the Commissioners, it becomes the duty of the Profession to take care that its rights are not infringed with impunity. The Act, 1st and 2nd Vic., cap. 56, sec. 33, empowers the Poor-law Commissioners to dismiss officers "unfit for, or incompetent to discharge the duties of their office."

Yours faithfully and obliged,

JUSTICE.

DR. STALLARD AND THE HOLBORN UNION.

To the Editor of "The Medical Press and Circular."

SIR,—The writer of your leader, Dec. 15th, on the Holborn Guardians, knows nothing about the subject. If the Guardians spend a shilling "contrary to law," the auditor would detect it, and make them pay it out of their own pockets. As you have chosen to associate my name with illegal practices, and to misrepresent my opinions, I claim the right to deny them by requesting the insertion of this letter.

Yours very obediently,

J. H. STALLARD.

7 King's road, London, W.C.

OVER-POPULATION AND LARGE FAMILIES.

To the Editor of "The Medical Press and Circular."

SIR,—Allow me to supply an omission in my letter on "Over-Population and Large Families" (which appeared in your number for Dec. 8). I ought to have added this:—

No one can say with truth that I have imported matters irrelevant into this debate. I have said that creeds and their teachings find no place in our scientific discussions, and to this I have myself adhered. Moreover, I have stated and asked nothing that was not to the point. The only question I have put as yet remains, after several months' waiting, unanswered, except by a few words in French from some anonymous correspondent, who had nothing to do with making the allusions I inquired about. Thus much to perfect the intention of my letter, which, having done, I can bestow no more time on the subject, which requires very truthful and accurate treatment on the part of those who engage in it. I am, Sir, Your obedient servant,

Brighton, Dec. 24th, 1869.

N. E. C. NOURSE, F.R.C.S.

LARGE FAMILIES.—Having devoted considerable space to the discussion of this question, we can receive no more letters for insertion upon the subject. There are one or two in type which must close the correspondence in our next.

DR. PULMER, Dromohair.—Your name has been entered on the subscription list, and we shall be glad to receive cases or reports for publication if approved.

LETTS'S DIARIES.—Messrs. Letts, Son, and Co., whose "Prescription Copyist" we noticed in a former number, have sent us specimen-sheets of their "Visiting List." Each leaf is ruled with thirty-one columns, for the days of the month, and the sheets are printed in several sizes, so as to slip in any ordinary pocket-book. We have also seen their "Appointment Diary," in which space is allotted for every hour of the year. To medical men with large practices this little volume will be found a very handy companion, and with their "Medical Ledger," a large quarto volume of 200 pages, will supply all that is required for the ordinary book-keeping of the general practitioner. We have personally used the diary for the last few years, and find it answers the purpose for which it is designed.

ALPHA.—In strict law unqualified gentlemen cannot find employment in any ships under Government inspection, though merchantmen bound for Australia, with a few passengers, sometimes take an apothecary without a diploma; this is very rare, and is not a course which we can advise.

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

The Causes and Treatment of Imperfect Digestion. By Arthur Leared, M.D. London: John Churchill and Sons.

Lessons in Elementary Botany. By Daniel Oliver, F.R.S. London: Macmillan and Co.

The Sanitary Condition of St. Pancras Infirmary. By Dr. Stevenson, the medical officer.

The Royal London Ophthalmic Hospital Reports. London: John Churchill and Sons.

Health of Newcastle and Gateshead. By Dr. Phillipson, the medical officer.

An Appeal to the People of England on the Recognition and Superintendence of Prostitution by Governments. By an English Mother.

Sin Licensed by Act of Parliament. Pacific Medical Journal. New York Medical Gazette. Boston Medical Journal. Nature. California Medical Gazette.

APPOINTMENTS.

ANNRESLEY, Surgeon J. C., in civil medical charge of Shalpole, is placed in executive charge of jail at that station, and is invested with powers of a magistrate under Section 23 of Criminal Procedure Code, such powers to be exercised within precincts of jail.

GAMGER, D. ARTHUR, has been elected Physician to the Royal Hospital for Sick Children, Edinburgh.

HARRISON, Surgeon-Major J. B., M.D., held executive charge of jail at Syalkot from August 11 to 22 last.

Deaths.

BAGG.—On the 20th inst., at his residence, 28 Talbot road, William Bagg, Esq., aged 66.

SMITH.—On the 20th inst., at Weston-super-Mare, Nathaniel Smith, F.R.C.S., late of Clifton, in his 88th year.

SMITHSON.—On Dec. 19th, at 3 Belgrave Road, Rathmines, Dublin, Jane, the beloved wife of Joseph S. Smithson, Esq.

WALLACE.—At Athboy, Co. Meath, from "fracture of the base of the skull," occasioned by a fall from his horse, Robert Bruce Wallace, Esq., L.R.C.S.I. and L.K. and Q.C.P.I., son of Dr. Wallace, of Trim, Co. Meath.

WOOD.—On the 13th inst., Samuel Wood, M.D., of Bandon, Co. Cork, aged 63.

PURE TASTELESS COD-LIVER OIL
IMPORTED BY BEWLEY AND DRAPER.

IT is this OIL, the use of which is directed by the MEDICAL COUNCIL, and which is ordered by the BRITISH PHARMACOPEIA.

DR. PEREIRA

Says, "The FINEST OIL is THAT WHICH IS MOST DEVOID OF COLOUR, ODOUR, and FLAVOUR."—"No other Livers but those of the TRUE COD can be obtained for the preparation of Oil at Newfoundland," a fact which is the best guarantee of the GENUINENESS OF THIS OIL.

In bottles, price 1s., 1s. 6d., 2s. 6d. and 4s. 6d.

Sold by **BEWLEY and DRAPER,**
23 MARY STREET, DUBLIN.

And may be had from all respectable Apothecaries in Town and country.

SIR J. MURRAY'S

PURE FLUID MAGNESIA

IS RECOMMENDED BY PHYSICIANS SINCE 1807 for Bile, Acidities, and Indigestion. They also order his COR-DIAL CAMPHOR (3 grs. per ounce) as the best restorative for weak nerves or low fevers. His LEMON SYRUP, mixed with either Fluid, forms a brisk Aperient for any age—bottles 1s. and 2s. 6d. To guard against false liquids the Patentee's labels are subscribed "Sir J. MURRAY, Physician to the Lord Lieut."

AERATED LITHIA WATER.

MESSRS. BLAKE, SANDFORD, and BLAKE are prepared to supply the LITHIA WATERS (of which they were the original manufacturers under Dr. GARROD's instruction) of any strength prescribed by the Profession for special cases. Those in constant use contain two grains and five grains in each bottle, either by itself or combined with BICARBONATE of POTASH or PHOSPHATE of AMMONIA. Also, POTASH, CITRATE of POTASH, SODA, SELTZER, VICHY, and MINERAL ACID WATERS, as usual.

BLAKE, SANDFORD, and BLAKE, Pharmaceutical Chemists,
47 PICCADILLY.

LIQUOR PEPSINÆ [LONG'S].

ʒss. to ʒj. for a dose, at or immediately after meals.

THE MOST CONCENTRATED AND EFFECTUAL PREPARATION OF PEPSINE KNOWN.

IT IS SWEET AND PALATABLE, EVEN FOR CHILDREN.

A drachm with 15 minims of muriatic acid, and 1 oz. of water, will dissolve 700 grains of moist fibrine at 100 degrees Fahr.

The Strength of each batch is carefully tested.

H. L. & Co. are warranted by the approbation of several Medical Men in recommending this preparation with confidence.

MANUFACTURED BY

HAMILTON, LONG, and Co., State Apothecaries, &c.,
3 and 4 Sackville street; 107 Grafton-street; 1 Rathmines terrace, Dublin.

THE SILVER MEDAL, PARIS, 1867.

SAVORY & MOORE'S
PANCREATIC EMULSION

Agreeable to the Taste. Readily Miscible in Milk, Water, and Wine. Not deteriorated by keeping.

N.B.—The "Reports of the Experience of Medical Men," &c. (Churchill and Son), and of Cases treated with the Emulsion, published in the 'Lancet,' 'Medical Press,' &c., are founded on the use of SAVORY and MOORE'S PREPARATIONS ONLY.

PANCREATINE

"Acts on azotized food either alkaline, acid, or neutral, (three times quicker than the gastric juice, pancreatic digestion, being to a very large extent)." —BARON CORVISART, 1859.

PANCREATINE, in Powder.

PANCREATINE WINE.

PANCREATIZED COD-LIVER OIL. The Labels give a test for Pancreatine, and a formula for making a Pancreatic Emulsion.

NOTICE.—The above are supplied in bulk for Hospital and Dispensing purposes.

SAVORY and MOORE'S
FOOD FOR INFANTS.

"THE BEST PREPARATION. Resembling mother's milk as closely as possible." —Dr. T. H. BARKER.

"A REAL IMPROVEMENT on the ordinary kinds of Liebig's Food." THE LANCET.

NO BOILING OR STRAINING.

Tins, 1s., 2s., 5s., and 10s.

149 NEW BOND STREET, AND ALL CHEMISTS.

KREOSOTE.

CAUTION TO BUYERS.—The Sole English Manufacturers of this article are the undersigned:—

THOMAS MORSON & SON,
31, 33, and 124, Southampton-row, London, W.C

BENZODYNE

A SOLUTION of the active principles of Gum Benzoin, separated from useless matter, the entire chemical products being conserved. The emulsion formed with PRICE'S BENZODYNE is an elegant medicine, recommended to the Profession as of great value in Chronic Cough, and all Pulmonary Diseases, as well as in Diarrhoea, Dysentry, &c. Prepared by Mr. PRICE, Analytical Chemist, 2 Lower Seymour street, London, W. 10s. per lb. sample bottles, enclosed to any Wholesale Druggist.

BARNES'S

PURE ETHERISED COD-LIVER OIL,

No. 1. Minimum strength }
No. 2. Medium strength } Dose, two fluid drachms.
No. 3. Maximum strength }

Prepared with the Finest Oil, and sold in Imperial Pints and Half-pints also per Gallon.

J. B. BARNES, PHARMACEUTICAL CHEMIST.

1 and 2 TREVOR TERRACE, PRINCES' GATE, S.W., LONDON.
Prize Medal awarded in 1851 for Valerianic Acid and Valerianates.

WHITE'S

SACCHARIZED HYDRATE OF MAGNESIA.

FOR INFANTS and FEMALES it will be found an invaluable Medicine. From its agreeable and pleasing taste, it has the advantage over all other preparations of Magnesia, as the most susceptible stomach will not reject it.

SOLE MANUFACTURERS AND PROPRIETORS,
BOILEAU and BOYD,

Wholesale Druggists and Manufacturing Chemists,
91, 92, and 93 Bride street, Dublin.

Wholesale Agents:—Barclay and Sons; Newbery and Sons; S. Maw and Son; W. Edwards, London; Raines and Co., Liverpool; Edinburgh, and York; Bewley, Hamilton, and Co.; the Apothecaries' Hall; Dr. Butler; George Oldham and Co., Dublin; Gratian and Co., Belfast.

Sold in bottles at 1s. and 2s. 6d. each, and in Winchester Quarts for Dispensing.

EVANS' STYPTIC.

THE Introduction of this Preparation to the notice of the Profession arose from the desire expressed by several eminent Physicians and many Patients to obtain an efficient Styptic at a moderate price—Ruspi's celebrated Styptic being so costly.

Dr. E. begs to state that the efficacy of the above Styptic has been tested for the past three years by several Medical Men in a variety of hemorrhages, in purpura, menorrhagia, &c., and it has met their approval.

[Dose].—A dessertspoonful with a dessertspoonful of cold water every second, third, or fourth hour.

SYRUPUS ACIDI CARBOLICI.

USEFUL IN CASES OF

PYROSIS, YEASTY VOMITING, and FLATULENCY.

Acid. Carbolic Cyst. gr. iv.

Tinct. Chloroform. Co. drachmam.

Syrupi Amygdalarum drachmas vii.

NOTE.—The disagreeable flavour of the Carbolic Acid is entirely concealed by this combination.

J. EVANS, M.D., STATE APOTHECARY AND CHEMIST
(by Special Appointment) to H.R.H. the Prince of Wales,
49 DAWSON STREET, DUBLIN.

COD-LIVER OIL.

NEW IMPORTATIONS, 1869.

NEWFOUNDLAND FINEST QUALITY,

9s. 6d. per gallon, including tin.

LIGHT-BROWN NORWEGIAN,

6s. 6d. per gallon, including tin.

Remittance to accompany order. P. O. O. payable at the Chief-Office.

T. KEATING'S, 79 St. Paul's Churchard, London.

The Proprietor begs to assure the Profession that the above are the finest qualities imported.

LIQ. CHLORODYNII (H. L. AND CO.)
VEL CHLORODYNE.

THE recent controversy regarding this valuable therapeutic agent has induced Messrs. HAMILTON, LONG and Co. to present to the profession a Chlorodyne of known strength and composition, which they apprehend will be deemed an advantage.

Dose 10 to 20 drops.

Acid. Hydrocyanic dil. 4 M. in 1 Dram.

Chloroform 8 M. " " "

Morph Hydr. 4 gr. " " "

LABORATORIES.—

3 and 4, LOWER SACKVILLE STREET, and } DUBLIN.
